When a part of North America's remaining forestland is cleared for cultivation, when its trees are felled for timber or ravaged by blight or fire, many people regret the loss of habitat, property, life, and natural beauty. Less often considered but of vital importance is the release of carbon that also results from the loss of vegetative cover. Plants, through photosynthesis, convert carbon dioxide to carbohydrates and can thus store carbon within their tissue. This storage is only temporary, as vegetation ultimately releases carbon back to the atmosphere through decomposition. Forest vegetation accounts for approximately 90 percent of the vast amounts of carbon stored in the biomass of terrestrial ecosystems. Forty percent is currently contained within the temperate and boreal regions of the world. The remainder is concentrated primarily in tropical forests, which typically have greater average biomass and can thus store more carbon. Current concern over the possible global effects of increasing concentrations of atmospheric carbon dioxide must therefore take into account the effects of changing land use on the distribution and cycling of carbon.

Most discussions about the growing problem of atmospheric carbon dioxide center, not on living vegetation, but on fossil fuels (primarily coal, oil, and natural gas—the fossilized remains of photosynthesizing organisms). Since the early 1800s, the ever increasing use of fossil fuels has liberated tremendous quantities of carbon dioxide. The world's oceans and diminished forests cannot provide an endless sink for this carbon, and approximately one-half the carbon dioxide gas produced each year from human activities now accumulates in the atmosphere. With the current rate of increase in the use of fossil fuels, atmospheric carbon could double in as little as fifty years. Many scientists anticipate that as a result, the average global temperature will rise, perhaps by 2°C. The wide range of effects of such a warming could include melting of the polar icecaps and shifts in climatically suitable crop zones.

What many people don't realize is that the amount of carbon released by industry every year is equal to less than 0.5 percent of the total reserve carbon held in vegetation and soil. This implies that relatively small changes in the area or productivity of the world's vegetation can have a great impact, for better or for worse, on the carbon balance. Unfortunately, over much of the earth's surface, soils are currently being degraded and forests cut down at an alarming rate. And deforested areas, in addition to no longer being able to absorb carbon, are themselves sources of carbon. Land clearance in the tropics, for example, which is proceeding at an estimated rate of one percent of the land area every year, may contribute half again as much carbon dioxide as is released by the combustion of fossil fuels. The preservation of all possible reservoirs, or sinks, of carbon has become critical, and detailed studies of the world's temperate forests, to identify areas where intensive forest management can enhance carbon accumulation in the future, may prove of great value.

Inventories of current carbon reserves in temperate forests give us a snapshot of one moment in a long history of forest change. They provide only a static picture of a dynamic process. To place this process in perspective, we need to understand the historical alterations of forest ecosystems that have led to the present distribution of biomass and carbon. Before reconstructing the carbon dynamics of a region, we must estimate the carbon pool existing at the start of the time period being considered. Carbon losses resulting from deforestation and cultivation and carbon gains resulting from reforestation can then be documented. Finally, we can determine the changes in carbon storage, taking into account both losses and gains of carbon through time.

W S Hooks, Archives of the Great Smoky Mountains National Park

J S Coovert, Mississippi Department of Archives and History

Once we establish this trajectory of change, we can use it as a guide to predicting and controlling future trends.

The landscapes of the southeastern United States, extending westward from Delaware to Arkansas and southward to Louisiana and Florida, have undergone major modification in the past 250 years. And although other regions differ with respect to the details of land use, the transformations in this region exemplify the overall trends in carbon storage in the temperate zone.

In pre-Columbian times, the Southeast was covered with a diverse mosaic of forest communities, interspersed with some prairielike openings created by Indian burning and by locally dry or nutrient-poor soils. Using an early inventory of forest resources prepared in 1883 by botanist C. S. Sargent, director of the Arnold Arboretum at Harvard University, we can derive average biomass and carbon values for the original forests remaining in the 1880s. These uncut forests, representative of presettlement conditions, generally attained a greater biomass than many commercial forests reach today, in part because present-day exploitation of marketable timber is continual and in part because certain dominant forest types, and even species, no longer exist.

If we envision the presettlement vegetation of the Southeast as being in a state of equilibrium with natural disturbances such as fires and windthrows, we can use the period from A.D. 1700 to 1750 as a beginning point for considering changes in vegetation. With the coming of European settlers, forests east of the Mississippi River were increasingly opened up for cultivation and exploited for building materials and fuel. Fragmentation of the forests closely followed patterns of settlement in the 1700s. By 1790, most of the Atlantic seaboard was extensively settled, particularly the lowland tidewater regions of Virginia and the Carolinas. Portions of the lower Mississippi Valley were also settled early, with the wide levees of the Red and Mississippi rivers cleared first for the production of sugar cane. Settlement of the interior of the Southeast proceeded along valleys between the Appalachian and Cumberland mountains, until the discovery of gaps in the Cumberlands permitted settlers to transport their families and belongings over the mountains. The frontier receded rapidly as the population grew, with settlements reaching western Louisiana and Arkansas by 1840.

The Industrial Revolution and accompanying mechanization accelerated the pace of destruction of the southeastern forests. Before the end of the eighteenth century, William Dunbar, a plantation owner in the Tunica Hills of Mississippi and Louisiana, combined the use of the cotton gin, introduced in 1793, and the principle of contour farming. The western Florida parishes of southeastern Louisiana quickly became a major cotton-producing area. In the early 1800s, railroad lines were established to connect plantations along tributaries to the Mississippi River, and the export of cotton increased. By the 1850s, the stretch of fertile hills from Natchez,

In about 1700, forests in the southeastern United States and other parts of eastern North America began to recede. Trees were felled for many purposes, including the clearing of land and the gathering of building materials and fuel. As recently as the 1920s, the tanning industry in the Great Smoky Mountains used the bark of hemlock trees, far left, leaving the logs to rot once they had been stripped. Increased mechanization quickened the pace of forest destruction, and by the end of the last century, many lumbering operations, such as the sawmill in Greenville, Mississippi, left, were served by railroads. George Inness's 1855 painting The Lackawanna Valley, *below, shows clearly how the combined impacts of settlements, cultivation, and railroads reduced the vast forests to little more than patchy remnants.*

National Gallery of Art, Washington

With the introduction of the cotton gin in 1793, cotton yields went up, putting pressure on the forests. By 1850, plantations along the lower Mississippi River had replaced native magnolia and beech trees.

Mississippi, to Saint Francisville, Louisiana, produced some of the greatest cotton yields in the South. One result of increased cultivation of the land was a rapid change in forest cover and composition. As plantations expanded, majestic forests of giant magnolia (*Magnolia grandiflora*) and beech (*Fagus grandifolia*) trees, recorded in the first land surveys of the area, were replaced by open fields.

By 1850, the federal government was conducting an agricultural census every ten years. Using decennial census data, we can estimate the proportion of land remaining in virgin forest, that in cultivation, and that reverting to secondary forest. These records show that a major decrease in forest area occurred between 1750 and 1850 in the South. By 1880, less than 35 percent of the Southeast remained in virgin forest, concentrated for the most part in the southern Appalachian Mountains, the Mississippi River bottomlands, the Ozark and Ouachita mountains of Arkansas, and the Gulf Coastal Plain pinelands. Beginning in the 1890s, the remaining tracts of virgin timber in the southern Appalachians and the Gulf Coastal Plain were exploited for lumber, turpentine, and shipbuilding. Some wooden structures from this era, made from the valuable and decay-resistant heartwood of virgin longleaf pine (*Pinus palustris*), are still standing on the coastal plain.

Some forest recovery had occurred after the Civil War as the average size of farms decreased and sharecropping increased. The resultant old-field succession on abandoned land led to the development of secondary forests in the southeastern United States. In the Piedmont of Georgia, for example, up to 30 percent of the land area reverted to forests at this time. Even with this partial recovery of secondary forests in the Piedmont, however, the net result of removal of virgin forest, together with cultivation, erosion, and impoverishment of the soil, was a pronounced depletion of carbon reserves.

Don Nugent

To transport the cotton produced on the fertile southern plantations, steamboats plied the Mississippi. Plantations not situated directly along the waterway delivered their cotton to the river by railroad.

Lithograph by Currier and Ives of William Walker's 1883 *Cotton Plantation*, The Historic New Orleans Collection

On average, between 1750 and 1950 the southeastern United States released 0.13 petagrams (1 petagram = 10^{15} grams) of carbon each year. During this period, the area lost a total of 28.2 petagrams of carbon from the oxidation of vegetation and soil carbon.

Replenishment of carbon reserves did not begin until the mid-1900s, when conservation and forest-management practices started to take effect. The U.S. Forest Service, created in 1928, conducts intensive inventory and management of remaining forest resources. Virgin forests currently occupy less than one percent of their former area in the Southeast, persisting only in small, isolated stands. Upland old-field succession and intensively managed, commercial forest holdings, however, have continued to add to the amount of biomass in the vegetation. In the Piedmont area, where the boll weevil epidemic of the 1920s led to the abandonment of much farmland, regeneration of the pine forests has been particularly extensive. Today, about 95 percent of all forest tracts in the Southeast are categorized as commercial forest and are under direct Forest Service supervision. Forest Service practices of restocking and selected harvesting, which make possible the control of species composition and stand density, have resulted in a net gain in biomass and carbon on these lands since the 1950s. Consequently, as its forests capture carbon dioxide and convert it to wood, the Southeast today serves as a net sink for carbon. This region, representing 15 percent of the world's temperate forest area, illustrates the potential for counterbalancing the effects of continued deforestation elsewhere.

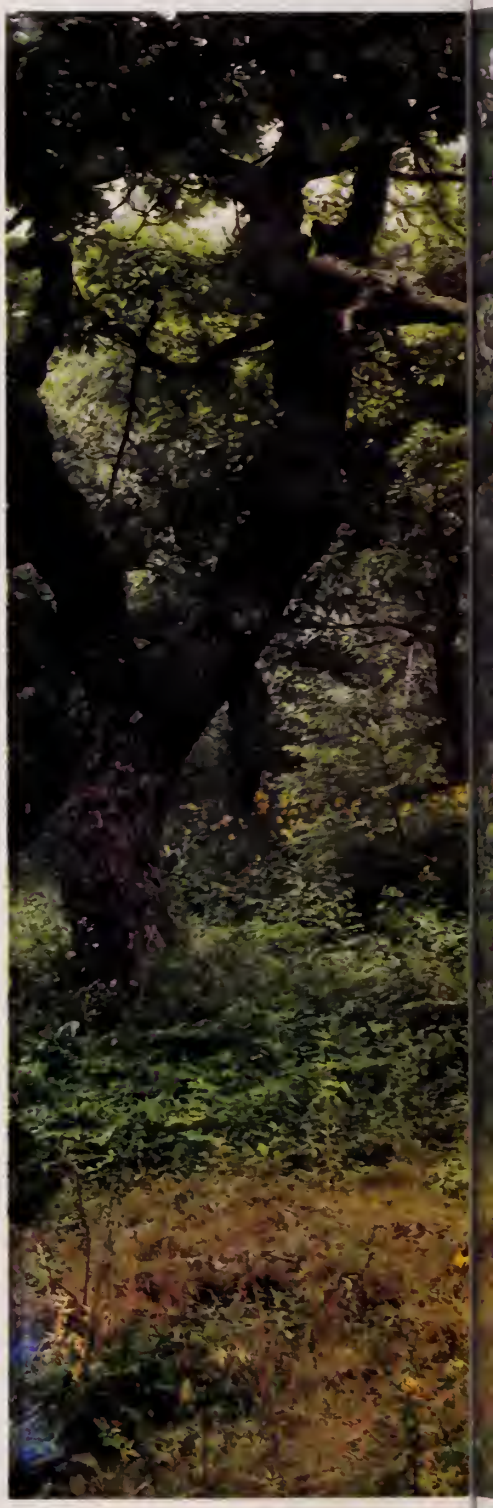
Proper forest management, with an eye to approaching the upper limits of forest growth and hence maximum carbon gain, also necessitates vigilance against disease. For example, when the American chestnut (*Castanea dentata*), a dominant canopy species in the southern Appalachians at the turn of the century, succumbed to blight in the 1920s, the result was a major change in forest composition and biomass. Originally distributed along the Appalachian mountain chain from Massachusetts to northern Georgia, chestnut trees once attained a height of up to 115 feet and a diameter at breast height of 8.5 feet. Reaching largest size and greatest abundance in the mountains of eastern Tennessee and western North Carolina, this species once occupied up to 60 percent of the forest canopy. Tragically, a fungal parasite (*Endothia parasitica*) accidentally introduced from Asia in the early 1900s in a shipment of nursery stock was responsible for widespread die-off of mature chestnut trees. By 1925, this blight had spread into the southern Appalachians, and today, only stump sprouts of chestnut persist, rarely reaching reproductive maturity. The oaks and other hardwoods that have replaced chestnut in the Appalachians are smaller in stature than their predecessors. Recovery and regrowth of forest stands after major alterations, such as logging and blight, is a slow process. Decades of protection from continued lumbering would be required for the regeneration of a forest of giant oaks, yellow poplar, and other hardwoods comparable in biomass to the massive chestnut trees.

The balance between carbon source and carbon sink is clearly sensitive to changes in forest composition and land use. If the current gains in carbon storage in the Southeast are to be sustained, the area of managed, commercial forests and their high productivity must be stabilized or even increased. An economic policy that maintained greater net growth than harvest would further enhance the capability of southeastern forests to gain carbon.

This capability is currently threatened, however, by active deforestation of the southern bottomland forests. The Mississippi Valley, once densely forested with tupelo gum (*Nyssa aquatica*) and bald cypress (*Taxodium distichum*), is one of the largest regions in the Southeast with great potential for accumulating biomass and carbon through forest regeneration. The fertile bottomlands along the Mississippi and other river systems in the Southeast, however, are now being rapidly converted to crop production, particularly of soybeans. The Forest Service estimates that at current rates of conversion, most of the remaining

Forest History Society

The American chestnut, devastated by blight in the early 1900s, was once a dominant species in the southern Appalachians. The present forest of smaller trees has less biomass and can store less carbon.



bottomland swamps in the Southeast will be drained, deforested, and planted in soybean fields by 1990. If, over the next several decades, the productivity of commercial forests remains at 1977 levels and the land area now occupied by virgin forest remains constant but the area of secondary forest decreases by as much as 10 percent, then the southeastern biota could return to being a source for atmospheric carbon. Even if the bottomland forests continue to be cut, continued reforestation of unused cropland in other portions of the region might compensate for the loss.

The historical patterns of change in the carbon cycle in the Southeast have been repeated elsewhere in the eastern United States, with certain regional differences. Between 1700 and 1850, the rates of carbon loss paralleled settlement patterns, with the most rapid and intense losses occurring within the original thirteen colonies. Between 1850 and 1900, farm abandonment and reforestation in New England—particularly Massachusetts, Rhode Island, and Connecticut—followed the initial land clearance, creating a temporary sink for carbon there.

In the area of the Midwest extending from Minnesota to Ohio, the magnitude and rate of carbon loss was greatest between 1850 and 1900. In the Great Lakes region, the logging of valuable stands of white pine (*Pinus strobus*) was succeeded by severe slash fires that liberated great quantities of carbon over a relatively short period of time. The depletion of soil carbon that resulted from such fires, for example, in the north of Michigan's Lower Peninsula, reduced soil fertility on sandy outwash plains, thereby prolonging forest recovery.

From 1900 to 1950, loss of carbon was widespread and rapid throughout the East, but overall, since 1950, the eastern United States has been a carbon sink, with only heavily agricultural states continuing to lose carbon each year. A wedge of low carbon values extends from Iowa and northern Missouri into Illinois, Indiana, and Ohio, corresponding to the cultivated land of the Corn Belt. Elsewhere in the East, recovery has been substantial. Furthermore, this trend toward carbon gain has been occurring during the last three decades throughout the temperate region of the Northern Hemisphere. An analysis of forest inventory data from the United States, Canada, Europe, and Asia, by T. V. Armentano of the Institute of Ecology and C. W. Ralston of Duke University, has shown that this current temperate-zone carbon sink has amounted to between 20 and 60 percent of the annual carbon released from the combustion of fossil fuels. Thus, forest recovery in the temperate zone has apparently at least slowed the increase in atmospheric carbon dioxide caused by the combustion of fossil fuels and the deforestation of the tropics.

The forests of eastern North America, which were a carbon source for most of the past 250 years, constitute 25 percent of the forests in the world's temperate zone and are at present one of the principal carbon sinks in that zone. But the levels of atmospheric carbon continue to rise. Regional studies of changing land-use patterns illustrate the spatial and temporal complexities involved in the storage and the exchange of carbon between the atmosphere and vegetation and soil. As we gain an appreciation of the magnitude and direction of the changes, we are beginning to develop a basis for sound management of forests, which play such an important role in the global carbon cycle. □

The forests of North America, such as this oak woods in North Carolina's Pisgah National Forest, make up a quarter of the world's temperate forests. Preservation of these carbon reservoirs must be part of any effort to slow the rising levels of carbon dioxide in the atmosphere.

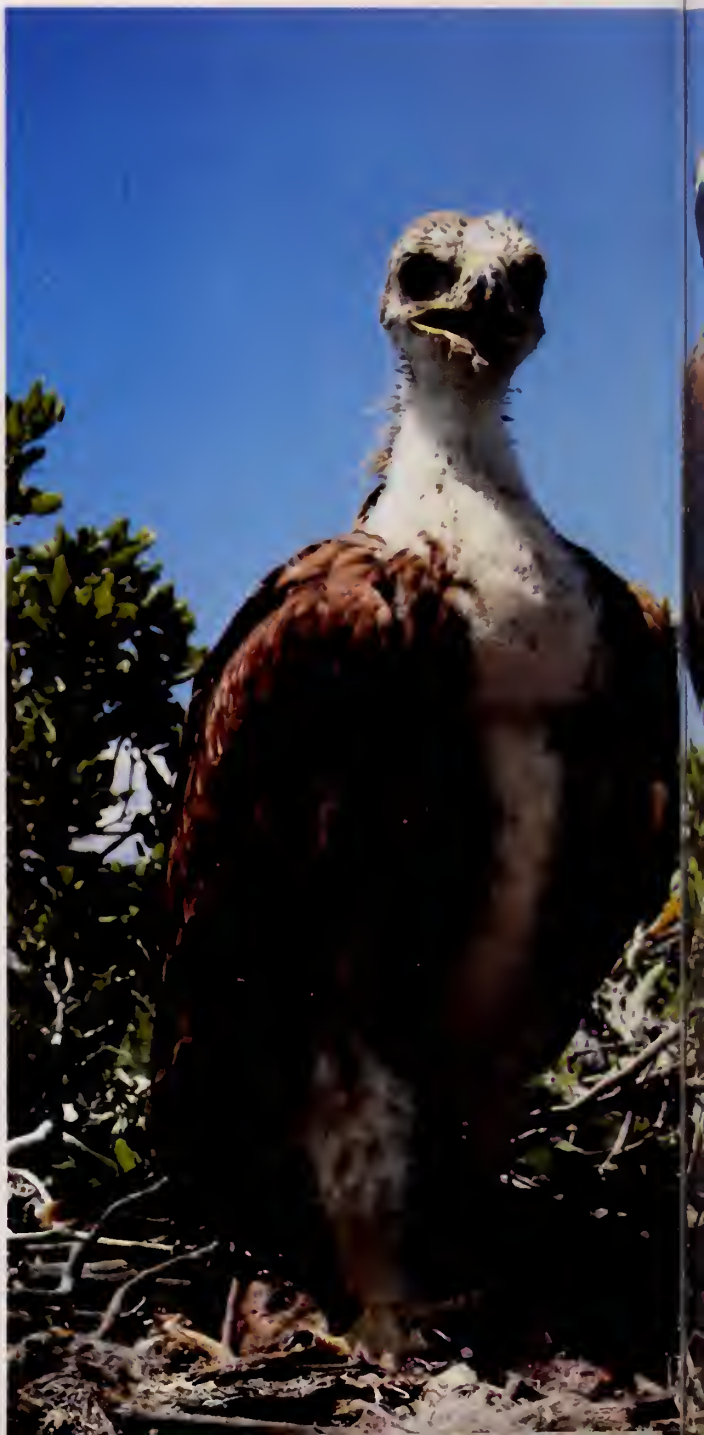
Spain's Imperial Eagle

Photographs by José Luis González

The Spanish imperial eagle (Aquila heliaca adalberti) *is among Europe's most handsome and most endangered birds. An estimated sixty pairs survive in Spain, primarily in Cáceres Province and in the Coto Doñana National Park, Andalusia, and a few pairs remain in Portugal. Spain has granted the eagle full legal protection, and healthy chicks are born every year, but the birds are still subject to pesticides and other poisons, hunters, and loss of habitat, notably to the planting of eucalyptus.*



The preferred habitat of the Spanish imperial eagle is savanna with scattered trees for nesting or sparse lowland forest. Forest clearance is forcing the birds closer to human activities, where their habitual fearlessness of humans increases their vulnerability. Mated pairs are monogamous and apparently stay together year-round. Parents share the task of building the nest and incubating the eggs. Both parents also bring back food for the young birds, although the female does most of this work. The male may refuse to deliver food to a disturbed nest site, waiting in a nearby tree for the female to collect it. Birds, small mammals (such as rabbits and hares), carrion, and an occasional reptile make up the bulk of the diet of both nestlings and adults.

Grande

Although the young birds are able to tear at prey by the time they are about five weeks old, they also continue to feed directly from the parent's bill until they fledge at about nine weeks.

Up to four chicks may hatch in a single brood, and a pecking order is soon established among the nestlings. The parents partition food among the young birds until late in the nestling period, but sometimes only one chick, usually the eldest and strongest, survives. The nestlings, often several days apart in age, lose their white down as they grow and acquire juvenile plumage. They are completely feathered by the time they are eight weeks old. The chick (left) is clearly the youngest; the other, older chicks sport more of the darker feathers typical of immature plumage. The young birds will not develop full adult plumage until they are three or four years old, but they may pair and breed before that time.

Once they have fledged, juveniles stay near the nest for two to three weeks, sometimes roosting in the nest itself. Adult Spanish imperial eagles appear to tolerate the presence of young of the same species within the nesting territory. Immature birds eventually disperse, generally remaining on the Iberian Peninsula but occasionally crossing the Strait of Gibraltar into Morocco.

Young Traders of Northern Nigeria

In Hausa society, where women live in strict Muslim seclusion, children play an active and indispensable economic role

Text and photographs by Enid Schildkrout

Thirty years ago, Erik Erikson wrote that "the fashionable insistence on dramatizing the dependence of children on adults often blinds us to the dependence of the older generation on the younger one." As a psychoanalyst, Erikson was referring mainly to the emotional bonds between parents and children, but his observation is a reminder that in many parts of the world, adults depend on children in quite concrete ways. In northern Nigeria, children with trays balanced on their heads, carrying and selling a variety of goods for their mothers or themselves, are a common sight in villages and towns. Among the Muslim Hausa, aside from being a useful educational experience, this children's trade, as well as children's performance of household chores and errands, complements the activity of adults and is socially and economically significant.

Children's services are especially important to married Hausa women, who, in accordance with Islamic practices, live in purdah, or seclusion. In Nigeria, purdah is represented not so much by the wearing of the veil but by the mud-brick walls surrounding every house or compound and by the absence of women in the markets and the streets. Women could not carry out their domestic responsibilities, not to mention their many income-earning enterprises, without the help of children, who are free from the rigid sexual segregation that so restricts adults. Except for elderly women, only children can move in and out of their own and other people's houses without violating the rules of purdah. Even children under three years of age are sent on short errands, for example, to buy things for their mothers.

Hausa-speaking people are found throughout West Africa and constitute the largest ethnic group in northern Nigeria, where they number over eighteen million. Their adherence to Islam is a legacy of the centuries during which Arabs came from the north to trade goods of North African and European manufacture. The majority of the Hausa are farmers, but markets and large commercial cities have existed in northern Nigeria since long before the period of British colonial rule. The city of Kano, for example, which was a major emporium for the trans-Saharan caravan trade, dates back to the eighth century. Today it has a population of about one million.

Binta is an eleven-year-old girl who lives in Kano, in a mud-brick house that has piped water, but no electricity. The household includes her fa-

The northern Nigerian city of Kano, which dates back to the eighth century, has a population of about one million. Reflecting the Islamic custom of keeping married women in seclusion, mud-brick walls surround every house or compound.

Two girls carrying bowls of cooked food stop to talk in the street. Free from the rules of purdah, children move in and out of their own and other people's houses. Women depend on them to sell food or other goods prepared at home.

ther and mother, her three brothers, her father's second wife and her three children, and a foster child, who is the daughter of one of Binta's cousins. By Kano standards, it is a middle-income family. Binta's father sells shoes, and her mother cooks and sells bean cakes and *tuwo*, the stiff porridge made of guinea corn (*Sorghum vulgare*), which is the Hausa staple. Binta described for me one day's round of activities, which began very early when she arose to start trading.

"After I woke up, I said my prayers and ate breakfast. Then I went outside the house to sell the bean cakes my mother makes every morning. Soon my mother called me in and asked me to take more bean cakes around town to sell; she spoke to me about making an effort to sell as much as I usually do. I sold forty-eight bean cakes at one kobo each [one kobo is worth one and a half cents]. After I returned home, some people came to buy more cakes from me. Then I went out for a second round of trading before setting out for Arabic school. I study the Koran there every morning from eight to nine.

"When school was over, I washed and prepared to sell *tuwo*. First my mother sent me to another neighborhood to gather the customers' empty bowls. I also collected the money from our regular customers. My mother put the *tuwo* in the bowls and told me the amount of money to collect for each. Then I delivered them to the customers.

"On my way home, a man in the street, whom I know, sent me on an errand to buy him fifteen kobo worth of food; he gave me a reward of one kobo. I then sold some more *tuwo* outside our house by standing there and shouting for customers. When the *tuwo* was finished, I was sent to another house to buy some guinea corn, and one of the women there asked me to bring her one of my mother's big pots. The pot was too heavy for me to carry, but finally one of my brothers helped me take it to her.

"When I returned, my mother was busy pounding some grain, and she sent me out to have some locust bean seeds pounded. She then sent me to pick up three bowls of pounded guinea corn, and she gave me money to take to the woman who had pounded it. The woman told me to remind my mother that she still owed money from the day before.

"When I came home I was sent out to trade again, this time with salt, bouillon cubes, and laundry detergent in small packets. Afterward I prepared some pancakes using ingredients I bought myself—ten kobo worth of flour, one kobo worth of salt, five kobo worth of palm oil, and ten kobo worth of firewood. I took this food outside to sell it to children.

"My mother then gave me a calabash of guinea corn to take for grinding; my younger sister also gave me two calabashes of corn to take. The man who ran the grinding machine advised me that I should not carry such a large load, so I made two trips on the way back. He gave me and my younger brothers, who accompanied me, one kobo each.

"I was then told to take a bath, which I did. After that I was sent to visit a sick relative who was in the hospital. On the way I met a friend, and we took the bus together. I also bought some cheese at the market for five kobo. I met another friend on the way home, and she bought some fish near the market for ten kobo and gave me some. I played on the way to the hospital. When I got home,

Having purchased a supply at the market, two girls arrange kola nuts for resale according to size and quality. The nuts, chewed as a stimulant by adults, are kept fresh by a moist piece of burlap laid in the tray.

I found the women of the house preparing a meal. One of them was already eating, and I was invited to eat with her.

"After nightfall, I was sent to take some spices for pounding, and I wasted a lot of time there. The other children and I went to a place where some fruits and vegetables are sold along the street. We bought vegetables for soup for fifty kobo, as my mother had asked me to do. By the time I got home it was late, so I went to sleep."

Binta's many responsibilities are typical for a girl her age. Like many women, Binta's mother relies upon her children in carrying out an occupation at home. Although purdah implies that a woman will be supported by her husband and need not work, most Hausa women do work, keeping their incomes distinct from the household budget. Women usually cook one main meal a day and purchase their other meals from other women. In this way they are able to use their time earning a living instead of performing only unpaid domestic labor.

Among the Hausa, men and women spend relatively little time together, eating separately and, except in certain ritual contexts, rarely doing the same things. Differences in gender are not as important among children, however. In fact, it is precisely because children's activities are not rigidly defined by sex that they are able to move between the world of women, centered in the inner courtyard of the house, and the world of men, whose activities take place mainly outside the home. Children of both sexes care for younger children, go to the market, and help their mothers cook.

Both boys and girls do trading, although it is more common for girls. From the age of about five until marriage, which is very often at about age twelve for girls, many children like Binta spend part of every day selling such things as fruits, vegetables, and nuts; bouillon cubes, bread, and small packages of detergent, sugar, or salt; and bowls of steaming rice or *tuwo*. If a woman embroiders, children buy the thread and later take the finished product to the client or to an agent who sells it.

Women in purdah frequently change their occupations depending on the availability of child helpers. In Kano, women often trade in commodities that can be sold in small

quantities, such as various kinds of cooked food. Sewing, embroidery, mat weaving, and other craft activities (including, until recently, spinning) are less remunerative occupations, and women pursue them when they have fewer children around to help. Unlike the situation common in the United States, where children tend to hamper a woman's ability to earn money, the Hausa woman finds it difficult to earn income without children's help. Often, if a woman has no children of her own, a relative's child will come to live with her.

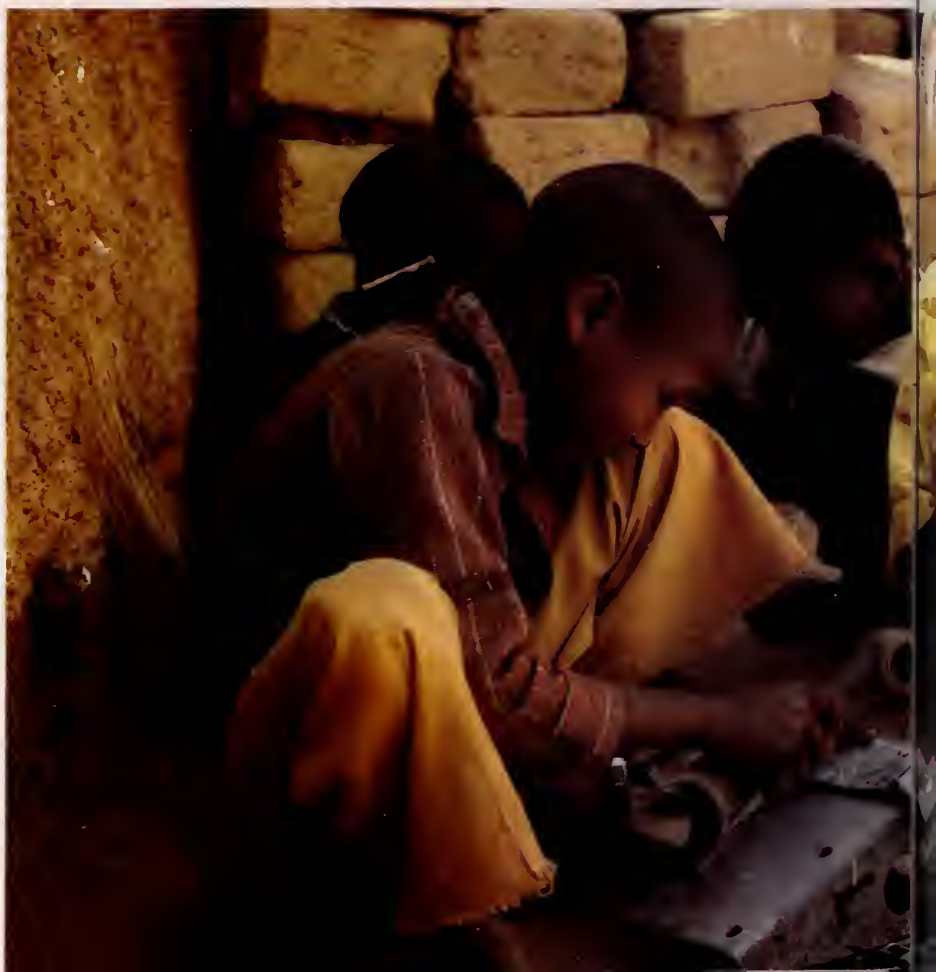
Child care is another service children perform that benefits women. It enables mothers to devote themselves to their young infants, whom they carry on their backs until the age of weaning, between one and two. Even though women are always at home, they specifically delegate the care of young children to older ones. The toddler moves from the mother's back into a group of older children, who take the responsibility very seriously. Until they are old enough, children do not pick up infants or very young children, but by the age of nine, both boys and girls bathe young children, play with them, and take them on errands. The older children do a great deal of direct and indirect teaching of younger ones. As soon as they can walk, younger children accompany their older siblings to Arabic school. There the children sit with their agemates, and the teacher gives them lessons according to their ability.

Much of a child's activity is directed toward helping his or her par-

Children too young to be entrusted with the care of infants often imitate the way women carry babies on their backs. The six-year-old above has a doll, but other children improvise with pillows or bits of firewood.

While washing clothes at home, a woman keeps her infant in close physical contact, safe from such dangers as livestock or fire. After children are weaned, older children are expected to help with their care.

ents, but other relatives—grandparents, aunts, uncles, and stepmothers—and adults living in the same house as servants or tenants may call on a child for limited tasks without asking permission of the parents. Like other Muslims, Hausa men may have up to four wives, and these women freely call on each other's children to perform household chores. Even strangers in the street sometimes ask a child to do an errand, such as delivering a message, particularly if the chore requires entering a house to which the adult does not have access. The child will be rewarded with a small amount of money or food.



Adults other than parents also reprimand children, who are taught very early to obey the orders of grown-ups. Without ever directly refusing to obey a command, however, children do devise numerous strategies of noncompliance, such as claiming that another adult has already co-opted their time or simply leaving the scene and ignoring the command. Given children's greater mobility, there is little an adult can do to enforce compliance.

Besides working on behalf of adults, children also participate in a "children's economy." Children have their own money—from school allowances given to them daily for the purchase of snacks, from gifts, from work they may have done, and even from their own investments. For example, boys make toys for sale, and they rent out valued property, such as slide viewers or bicycles. Just as women distinguish their own enterprises from the labor they do as wives, children regard the work they do for themselves differently from the work they do on behalf of their mothers. When Binta cooks food for sale, using materials she has purchased with her own money, the profits are entirely her own, although she may hand the money over to her mother for safekeeping.

Many girls begin to practice cooking by the age of ten. They do not actually prepare the family meals, for this heavy and tedious work is primarily the wives' responsibility. But they do carry out related chores, such as taking vegetables out for grinding, sifting flour, and washing bowls. Many also cook food for sale on their own. With initial help from their mothers or other adult female relatives, who may give them a cooking pot, charcoal, or a small stove, children purchase small amounts of ingredients and prepare various snacks. Since they

Older children do a lot of direct and indirect teaching of younger ones. Here, a boy who attends primary school demonstrates at home how to write in English, using chalk on the cement pavement of the courtyard.

Children make most of their own toys, and sometimes sell them to other children. With the author as a steady customer, these boys set up a "company" to manufacture toy cars, trucks, and airplanes from tin cans, bottle tops, and plastic box tops.

sell their products for less than the adult women do, and since the quantities are very small, their customers are mainly children. Child entrepreneurs even extend credit to other children.

Aisha is a ten-year-old girl who was notoriously unsuccessful as a trader. She disliked trading and regularly lost her mother's investment. Disgusted, her mother finally gave her a bit of charcoal, some flour and oil, and a small pot. Aisha set up a little stove outside her house and began making small pancakes, which she sold to very young children. In three months she managed to make enough to buy a new dress, and in a year she bought a pair of shoes. She had clearly chosen her occupation after some unhappy trials at street trading.

In the poorest families, as in Aisha's, the profit from children's work goes toward living expenses. This may occur in households that are headed by divorced or widowed women. It is also true for the *almajirai*, or Arabic students, who often live with their teachers. The proceeds of most children's economic activity, however, go to the expenses of marriage. The income contributes to a girl's dowry and to a boy's bridewealth, both of which are considerable investments.

The girl's dowry includes many brightly painted enamel, brass, and glass bowls, collected years before marriage. These utensils are known as *kayan daki*, or "things of the room." After the wedding they are stacked in a large cupboard beside the girl's bed. Very few of them are used, but they are always proudly displayed, except during the mourning period if the husband dies. *Kayan daki* are not simply for conspicuous display, however. They remain the property of the woman unless she sells them or gives them away. In the case of divorce or financial need, they can provide her most important and immediate source of economic security.

Kayan daki traditionally consisted of brass bowls and beautifully carved calabashes. Today the most common form is painted enamel bowls manufactured in Nigeria or abroad. The styles and designs change frequently, and the cost is continually rising. Among the wealthier urban women and the Western-educated women, other forms of modern household equipment, including electric appliances and china tea sets, are becoming part of the dowry.

The money a young girl earns on her own, as well as the profits she brings home through her trading, are invested by her mother or guardian in *kayan daki* in anticipation of her marriage. Most women put the major part of their income into their daughters' *kayan daki*, as well as helping their sons with marriage expenses. When a woman has many children, the burden can be considerable.

For girls, marriage, which ideally coincides with puberty, marks the transition to adult status. If a girl marries as early as age ten, she does not cook for her husband or have sexual relations with him for some time, but she enters purdah and loses the freedom of childhood. Most girls are married by age fifteen, and for many the transition is a difficult one.

Boys usually do not marry until they are over twenty and are able to support a family. They also need to have raised most of the money to cover the cost of getting married. Between the ages of eight and ten, however, they gradually begin to move away from the confines of the house and to regard it as a female domain. They begin taking their food outside and eating it with friends, and they roam much farther

Hausa women usually engage in some form of enterprise; most of their profits are invested in their children's marriage expenses. Working at home, a woman, right, weaves a mat for sale. This woman is a co-wife to the woman shown with her daughter, below right. As Muslims, Hausa men may have up to four wives, who often call on one another's children to perform household chores. The young girl carrying a tray on her head, below, has small quantities of goods for sale—bouillon cubes and packets of salt, sugar, and detergent. Children usually trade on behalf of their mothers or other adults but they may also earn money from their own small investments.

than girls in their play activities. By the onset of puberty, boys have begun to observe the rules of purdah by refraining from entering the houses of all but their closest relatives. In general, especially if they have sisters, older boys spend less time than girls doing chores and errands and more time playing and, in recent years, going to school. Traditionally, many boys left home to live and study with an Arabic teacher. Today many also pursue Western education, sometimes in boarding school. Although the transition to adulthood is less abrupt for boys, childhood for both sexes ends by age twelve to fourteen.

As each generation assumes the responsibilities of adulthood and the restrictions of sexual separation, it must rely on the younger members of society who can work around the purdah system. Recently, however, the introduction of Western education has begun to threaten this traditional arrangement, in part just by altering the pattern of children's lives.

The Nigerian government is now engaged in a massive program to provide Western education to all school-age children. This program has been undertaken for sound economic and political reasons. During the colonial period, which ended in the early 1960s, the British had a "hands-off" policy regarding education in northern Nigeria. They ruled through the Islamic political and judicial hierarchy and supported the many Arabic schools, where the Koran and Islamic law, history, and religion were taught. The British discouraged the introduc-

tion of Christian mission schools in the north and spent little on government schools.

The pattern in the rest of Nigeria was very different. In the non-Muslim areas of the country, mission and government schools grew rapidly during the colonial period. The result of this differential policy was the development of vast regional imbalances in the extent and level of Western education in the country. This affected the types of occupational choices open to Nigerians from different regions. Despite a longer tradition of literacy in Arabic in the north, few northerners were eligible for those civil service jobs that required literacy in English, the language of government business. This was one of many issues in the tragic civil war that tore Nigeria apart in the 1960s. The current goal of enrolling all northern children in public schools, which offer training in English and secular subjects, has, therefore, a strong and valid political rationale.

Western education has met a mixed reception in northern Nigeria. While it has been increasingly accepted for boys—as an addition to, not a substitute for, Islamic education—many parents are reluctant to enroll their daughters in primary school. Nevertheless, there are already many more children waiting to get into school than there are classrooms and teachers to accommodate them. If the trend continues, it will almost certainly have important, if unintended, consequences for purdah and the system of child enterprise that supports it.

Children who attend Western school continue to attend Arabic school, and thus are removed from the household for much of the day. For many women this causes considerable difficulty in doing daily housework. It means increased isolation and a curtailment of income-producing activity. It creates a new concern about where to obtain the income for children's marriages. As a result of these practical pressures, the institution of purdah will inevitably be challenged. Also, the schoolgirl of today may develop new skills and new expections of her role as a woman that conflict with the traditional ways. As Western education takes hold, today's young traders may witness a dramatic change in Hausa family life—for themselves as adults and for their children. □

Shakespeare–The Poet's Worlds

by S. Schoenbaum

In 1592 the playwright Robert Greene, dying in miserable squalor, lashed out, in his *Groatsworth of Wit, Bought with a Million of Repentance*, at a successful professional rival who—lacking even a university degree!—had the impudence to fancy himself "the only Shake-scene in a country." This is our first record of Shakespeare in London. He was then twenty-eight and had been in the capital long enough to establish himself and attract envious notice. Some years earlier, then, he had boldly set out from Stratford-upon-Avon on the high road to London, a hundred miles distant.

What had possessed him to pull up stakes and leave behind—for the time—his wife and three small children? In an early play, *The Taming of the Shrew*, Petrucchio speaks of "such wind as scatters young men through the world / To seek their fortunes further than at home, / Where small experience grows." Some such wind carried Shakespeare from the little Warwickshire town of his origins to a London overflowing the ancient city walls: a magnet for foreign visitors, hub of the publishing trade, and—above all, for him—the center of theater. But Stratford had nurtured him, and unlike some of his literary colleagues, he never severed his provincial ties.

As a child plying his textbooks through the unmercifully long Elizabethan school day, he must have turned whenever possible to another, more seductive book. This was the book of nature open to him in the gardens, orchards, and hedgerows of leafy Stratford, along the Avon's banks, and in the beckoning fields and woodlands just outside. "Flowers I noted," the poet says in Sonnet 99, and in fourteen brief lines, the forward violet, the lily, the buds of marjoram, and the roses standing fearfully on thorns all find their place. Shakespeare's works constitute a brilliantly colored garden in which flowers, wild and cultivated, blossom side by side.

Along the river's bank the young Shakespeare would have noticed sedge, rushes (used to strew the floors of Tudor houses), and the tall reeds that thatched the roofs of humble cottages. In the stream the green leaves of the vagabond flags swayed to and fro in "the varying tide," while the willow trees growing along the water's edge cast their gray reflection. Traditionally, the willow symbolized forsaken love. Desdemona sings a song of willow before she dies, and in perhaps the most famous floral passage in Shakespeare, willow frames the scene of Ophelia's drowning.

If Shakespeare's works are a scented garden that invite the horticulturist's interest, they hold, too, the pleasures

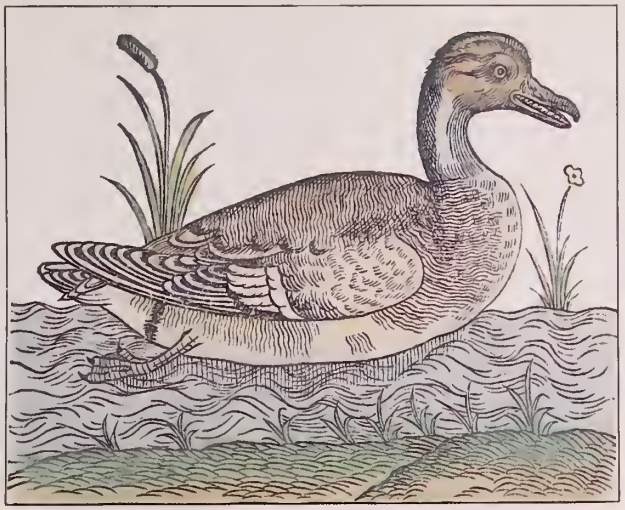
"Shakespeare: The Globe & the World," a special exhibition from the collection of the Folger Shakespeare Library in Washington, D.C., will be on view at the American Museum of Natural History from June 18 to September 20. This article is adapted from the catalog to the exhibition, Shakespeare: The Globe & the World, *by S. Schoenbaum, © 1979 by the Folger Shakespeare Library, published by Oxford University Press in association with the Folger Shakespeare Library.*

Shakespeare's birthplace in Stratford-upon-Avon was painted in 1834 by Phoebe Dighton.

A hand-colored woodcut of a fallow deer appears in Edward Topsell's Historie of Foure-footed Beastes *(London, 1607). A legend originating after Shakespeare's death has him poaching such deer on the grounds of Sir Thomas Lucy's estate, four miles upstream from Stratford.*



of the arboretum. Shakespeare names, among others, elm, pine, box, ash, oak, and aspen. The oak, although vulnerable to lightning, betokens strength; Coriolanus, in the Watch's words, is "the rock, the oak not to be wind-shaken." In all, Shakespeare's plant inventory comprises more than 150 varieties, according to one tabulation.

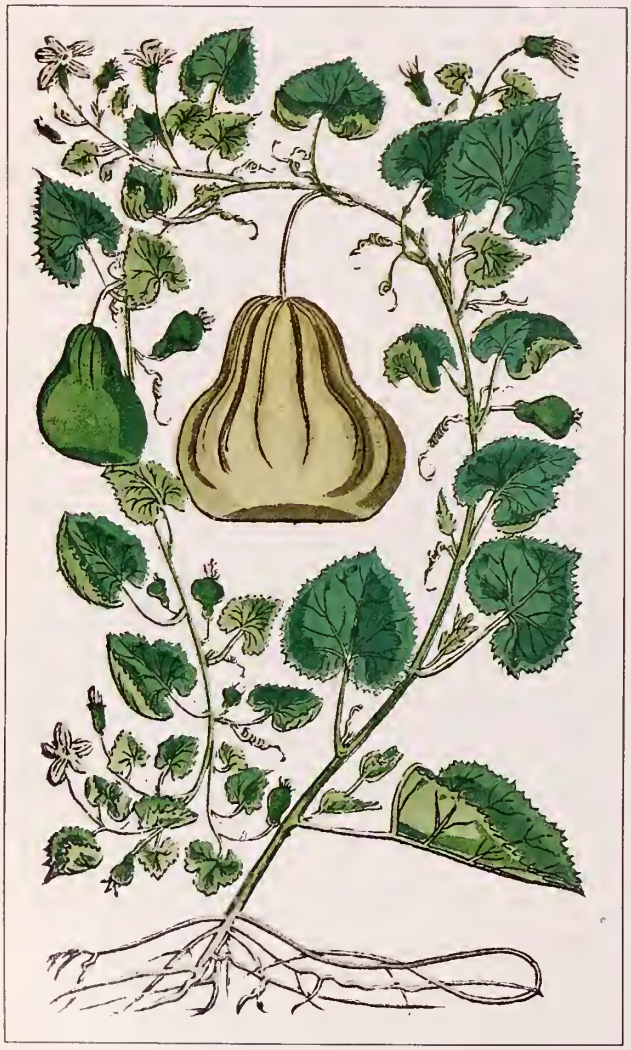
Bird references, while less numerous, occur often enough to keep a drowsy ornithologist awake. They include birds of prey and carrion (eagle, kite, raven, vulture, and owl), as well as game birds (woodcock, partridge), waterfowl (swan, wild goose, loon, dive-dapper, and mallard), and such familiar songsters as the blackbird, redbreast, and thrush. For his birdlore, as has often been noted, Shakespeare also draws upon inherited typologies: the phoenix rises from its ashes; the pelican feeds her young with her own blood.

Some of the other creatures the young Shakespeare would have encountered on, or near, his Warwickshire doorstep were the harmless, necessary cat; the farmer's dog barking at the beggar; the "breeding jennet, lusty, young, and proud" that "rushes, snorts, and neighs aloud." On neighboring farms, such as the one his Uncle Henry worked in Snitterfield, Shakespeare would have seen the livestock with their offspring. Poor Wat, the relentlessly hunted hare in *Venus and Adonis*, is part of a vernal world Shakespeare fondly evoked. Outrunning the wind, turning and crossing, bounding through gaps in hedges and fences, he reaches the illusory safety of the hilltop where he "stands on his hinder legs with list'ning ear,/To hearken if his foes pursue him still." The poet's sympathies notwithstanding, Shakespeare may well have hunted. Certainly other high-spirited youths of Warwickshire did so, and the plays and poems yield a sufficiency of knowledgeable allusion.

London offered different attractions. There Shakespeare acted, as well as wrote plays for his acting company. During his idle hours he could plunge into the life of the town. London, which conferred no degrees, became his university, providing the nonacademic context for that knowledge of the human heart, unrivaled in range and depth, which for many remains the most astonishing aspect of the Shakespearean achievement. Around him he could see a fair city full of folk and observe the inexhaustible pageant of everyday life.

Shakespeare saw the country folk come to town with their wares, on foot or in their carts, and he heard the market bell ring. To Grace Church Street, husbandmen brought corn and malt to sell at their standings in the great corn market, situated there since the Middle Ages.

The duck and the owl are depicted in Pierre Belon's L'Histoire de la Nature des Oyseaux *(Paris, 1555), a French naturalist's early attempt at bird classification. While taking cues from nature, Shakespeare also drew on legendary associations and birdlore, such as the belief that shrieking night owls bode ill, especially at a birth.*



The Stocks, in Cornhill Ward, were a marketplace for flesh and fish. Billingsgate, one of the main city wharves, also offered freshly caught fish, but not until much later—in 1696—did Parliament allow a daily market there. A small portion of Smithfield was reserved, as in times past, for marketing horses and cattle. Bakewell Hall, in the little ward of Bassings Hall, was immemorially "employed as a weekly marketplace for all sorts of woollen clothes broad and narrow, brought from all parts of this realm, there to be sold." Farmers fetched their poultry to Leaden Hall Market, where other commerce went on as well.

Tradesmen and sellers of wares kept shops everywhere: mercers and haberdashers on London Bridge, goldsmiths in Cheapside, pepperers and grocers in Bucklesbury, drapers in Candlewick Street, skinners in Bridge Row, stockfishmongers, cooks, and ironmongers in Thames Street, poulterers in Grace Street, while "the brewers for the most part remained near to the friendly waters of the Thames." In the old days the bakers of London were enjoined to sell no bread in shops or houses: only in the market in Bread Street. Such centralization had long since vanished in the wake of urban growth, but in a regulated economy nothing is more stringently controlled than the price and quality of the daily bread. Elizabeth's Privy Council still enforced the "statutes and ancient customs for making and retailing of all lawful sorts of bread."

In Elizabethan England, the Crown sought also to curb excess in apparel, but not very successfully. The fashionable reveled in luxurious materials (silks and velvets from Italy and France) ornamented with precious jewels. But if the upper classes consumed conspicuously, and the mercantile classes with balance-sheet moderation, many in this period lacked any means at all. They wore rags.

High- and low-born, whether in tatters or finery, people thronged to the capital. Of the magnets drawing the hurrying folk, one or two are especially conspicuous. Fronting the Cornhill stood the gigantic emporium that Sir Thomas Gresham, a mercer of London, had commissioned Flemish architects to build in imitation of the great Bourse at Antwerp. In the cloistered piazza of the Exchange, merchants gathered to conduct their affairs while above, in the Pawn, tradesmen—milliners, haberdashers, armorers, apothecaries, glass-sellers, and the rest—carried on their retail businesses in shops illuminated by wax-lights. Here one went for a mousetrap, a birdcage, a shoehorn, or a lantern. At the

A finely illustrated botanical book, or herbal, available in Shakespeare's time, was Den Nieuwen Herbarius *(Basel, 1550), from which this hand-colored picture of a gourd is reproduced. The author of* The New Herbal *was German botanist Leonhard Fuchs, after whom the fuchsia was named.*

Royal Exchange, Mammon had his London temple.

If one preferred God, Saint Paul's beckoned, although Mammon had established a foothold there too. To the Middle Aisle of Paul's, called Duke Humphrey's Walk, repaired the Westminister crowd—courtiers, wits, and gallants-about-town—to strut in their finery, observe and be observed. Lawyers, stationed at their pillars, received clients; wenches, masks clapped to their faces, arranged assignations. Meanwhile, divine services went on. In Paul's churchyard flourished the book trade—a relatively new industry. In the outpourings from the presses, Shakespeare found the literary sources for his comedies, histories, and tragedies.

Shakespeare also caught glimpses of the real world of intrigue and pomp, which as his history plays testify, he came to understand so well. That was when his troupe was summoned to Richmond or Greenwich or Whitehall—wherever Elizabeth kept her court—to participate in the festivities of the Christmas season.

Although the London panoramas tease rather than satisfy curiosity, they give us an inkling of what the Globe (and other bankside amphitheaters) looked like from the outside. We see the surrounding shrubbery and tenements; we see the competing arena in which chained and blinded bears were tormented by hungry dogs for the amusement of holidaymakers; and in the near distance, we see the silver-gliding Thames. The London theaters, each with an estimated capacity of some 3,000 spectators, were among the principal attractions of the metropolis for foreign visitors.

On 29 June 1613, during a performance of Shakespeare's *Henry VIII*, the thatched roof on the Globe playhouse caught fire, a wind fanned the flames, and within two hours the theater was reduced to rubble. Miraculously, no lives were lost. A year later the second Globe opened its doors to the public on the same site. This time the roof was prudently tiled. Shakespeare may well have decided that this was an opportune time to bid adieu to the multitudes who, for over two decades, had applauded his plays and rewarded him with material success. So he retired at twilight to New Place, the pretty house of brick and timber he had acquired in Stratford. Presumably, Shakespeare there cultivated his garden, which was celebrated for its vines.

On 25 April 1616, he was laid to rest in Holy Trinity Church where, fifty-two years earlier, he had been christened. Thus did he begin and end his days in Stratford. In between, London had provided a stage for supreme achievement. □

Although the Crown sought to curb excess in apparel, fashion enjoyed a renaissance in Elizabethan England. Below, a courtier and his lady are depicted in an anonymous watercolor sketch from the time of James I, the successor to Elizabeth I.

Peaceable Peccaries

Much snuggling and nuzzling enable these relatives of wild pigs to maintain cooperative and cohesive herds

by John A. Byers

In 1683, an anatomical account of a New World mammal was published in the *Philosophical Transactions* of the Royal Society of London. The beast had been brought alive to England and when it died was given to Dr. Edward Tyson for examination and dissection. Tyson had in hand a male of a species known today as the collared peccary, *Tayassu tajacu*. His wonderfully descriptive name for the animal was the Mexico musk-hog. Spanish explorers of the time also knew the animal and referred to it as the javelina (from the Spanish *jabalina*, or "spear," a reference to the animal's large canine teeth).

The collared peccary is one of three extant species in the family Tayassuidae. The tayassuids diverged from the true pigs, or Suidae, in the early Oligocene, about 40 million years ago, and differ from true pigs in several important respects. Like pigs, however, peccaries possess a tough, disk-shaped snout and have a proclivity to root. Although they were once cosmopolitan, peccaries are confined today to the New World. The collared peccary occurs over a huge range between Argentina and the American Southwest; its close relatives, the white-lipped peccary and the chacoan peccary, are found only in the tropics and subtropics. In the United States, collared peccaries occur in the southern regions of Texas, New Mexico, and Arizona.

Peccaries and pigs differ in many ways. To begin with, the former are much smaller: collared peccaries are about three feet in length, stand about a foot and a half at the shoulder, and weigh about fifty pounds; wild boars (from which domestic pigs were derived) may weigh up to ten times as much. The coats of peccaries are composed entirely of large, coarse bristles; those of pigs vary, but in general they have hair as well as bristles, the latter being more scattered, shorter, and less robust than the bristles of peccaries. Pigs have a simple stomach; peccaries have a multichambered stomach resembling that of the ruminants in form and, somewhat, in function. Pigs have rather primitive feet; peccaries have more specialized feet that show adaptations for running. The canine teeth of pigs curve outward, as in the wart hog; those of peccaries are straight and interlocking. Finally, the two groups differ with respect to litter size and social organization. Pigs give birth to large litters of small, relatively helpless young; mothers spend much time alone caring for their young in a nest or den; and there are no permanent social groups. Peccaries do have permanent social groups and females bear litters of only two young, which are able to walk soon after birth. As a result, mothers are able to rejoin their herd quickly.

I studied peccaries on the 3-Bar Wildlife Area, a sixty-square-mile research preserve maintained by the Arizona Department of Game and Fish. I was drawn to the collared peccary because, in the literature, there were tantalizing intimations that the species was highly social. A major goal of my earlier research had been to discover whether specific types of early experience lead to specific types of adult behavior in animals. More generally, what developmental strategies does each species use to achieve its level of social organization? This is, of course, a huge question, and one way to begin attacking it is to look for broad patterns at the ends of the spectrum of social organization, that is, in highly social and in nonsocial species. My intimations that peccaries would be at the high end of the spectrum turned out to be correct.

The social unit of peccaries is a cohesive herd, composed of equal numbers of males and females. This reflects a sex ratio at birth of 1:1 and the fact that individuals rarely disperse into new areas. Herd size in the American Southwest, and throughout Central America and South America, in those areas where reliable counts have been made, averages twelve to fifteen members. There is essentially no sexual dimorphism. Within herds, animals remain close to each other, and individuals become visibly upset and may utter loud, squalling cries if they lose contact with their fellows. Herds therefore act as a unit in which all individuals move, feed, and rest together.

Each herd occupies an exclusive home range about one square mile in size. Within each home range a network of peccary trails connects feeding locations and traditional resting sites, or bed-grounds. The animals give the strong impression that they possess a detailed "cognitive map" of the home range: when undisturbed, their movements are deliberate, and they choose energetically efficient paths (by angling up a hill rather than attacking it head-on or by contour-

Snuggling in their afternoon bed-ground, two peccaries typify the close contact maintained by these animals. The herd to which these peccaries belong will use another site for its nighttime bed-ground.

ing around the head of a canyon rather than crossing directly by going down and then up). Obviously, the animals know, in some sense, their destination (whether a bed-ground or a feeding ground) and they take the most efficient, but usually not the most direct, route to get there.

Herds also seem to know when they are near the borders of their home ranges. At these times, the peccaries increase the rate of deposition or secretion from their large dorsal gland, a scent organ present in both sexes that lies on the midline of the back, just anterior to the tail. Tyson made much of the dorsal gland in his 1683 article and, after examining in a withering fashion the hypotheses of his contemporaries that the structure was a second navel, a mammary gland, a urinary orifice, an intestinal orifice, or a spiracle for breathing, he correctly identified it as a scent gland.

But what is most particular in our *Hog*, and makes the greatest wonder; and differences it, from any other Animal I know of in the World; is the *Teat* or *Navill* or *Foramen* rather on the hinder part of the back. All who mention this *Animal*; look on this, as a thing so extraordinary, and uncommon; that I know not how their amazement has so far clouded their reason, as to betray them into most extravagant Conjectures, and opinions concerning it.

Scent marking is probably the way in which adjacent herds define the boundary between their home ranges. This seems plausible because the rate of actual interactions between herds is extremely low; in a year of field observations I saw herds come together only twice. In one of these instances, there was a flurry of short chases back and forth, then both herds drifted apart and bedded down within 1,000 feet of each other. In the other, the same two herds were together, feeding peacefully along the border between their home ranges when I found them; they slowly fed and ambled in separate directions.

I tested the idea that scent marking might be important in boundary definition by erecting fence posts at quarter-mile intervals along a ridge where the home ranges of three herds met. Peccaries investigated the posts but did not mark them. I then collected dorsal gland secretions from a captured member of a herd five miles away and placed it on the posts. Residents responded to this new odor by marking on top of it, often with such vigor that I could smell the posts from some distance and could see dorsal gland secretion dripping from them. This result suggested that peccaries recognized an unfamiliar dorsal gland scent and re-marked it to indicate that the area was occupied.

The dorsal gland, besides being used in scent marking, figures prominently in a cooperative social action I call the "mutual rub": two animals approach each other and stand side by side so that each rests its head against the other's rump; each then vigorously rubs the side of its head up and down over the other's rump and dorsal gland. This activity lasts about five seconds, and no doubt smears the oily secretion of each partner's dorsal gland onto the head and back of the other. Peccaries also spend much time nuzzling each other and lying in close contact—two activities that further promote the transfer of the secretion. The overall result is that each animal becomes an effective broadcaster of the dorsal gland scent, so much so that when herds were directly upwind from me, I could sometimes detect them by smell. This suggested to me that peccaries, with their keen sense

of smell, use a "cloud" of dorsal gland scent that surrounds each herd as a cue to judge their distance from the herd's center. Vision is certainly less important. Peccaries have notoriously poor eyesight and, if the wind is right, will blunder to within a few feet of an unconcealed, but motionless, person before taking flight.

Hearing may be the most important orienting mechanism. On several occasions I was very close to feeding herds as they drifted past me, and each time I was impressed by the sounds that envelop a feeding herd: the click of hoofs on rocks, the crunching and smacking sounds of chewing, and the periodic low grunting all herd members make. The low grunt is a repetitive flat sound, similar to the grunts made by pigs. Lost peccaries emit the sound almost constantly and appear to listen for a return call; they quickly approach animals in the vicinity that respond. Thus, group cohesion seems to be promoted primarily through hearing and olfaction.

Why do collared peccaries stay close together and why is vision not an important means of doing so? The species probably evolved from other peccaries in the Pliocene rain forests of South America. Predation by large cats is today, and no doubt was then, a serious threat, constituting a selective pressure strong enough to cause individual peccaries to bunch together. In the dense rain forest understory, these low-slung beasts would have had trouble using vision to keep in contact with each other, but they could have used sounds and smells (to which vegetation is more "transparent") to do so. Bird watchers are familiar with this phenomenon. In thick vegetation, far more birds can be heard than seen.

The tendency for peccaries to stay close together is so strong that most individuals probably never leave the herd into which they are born. As a result, herds most likely comprise a group of closely related animals. This, in turn, has probably been responsible for the evolution of the highly cooperative behavior that herd members extend toward each other. (Chacoan and white-lipped peccaries also live in herds, and white-lipped groups can exceed 200 individuals. Essentially nothing is known about the constancy of herd composition or social behavior in these two species.)

Cooperative behavior among peccaries can be crucial in winter. In central Arizona, winter nights are usually chilly and sometimes downright cold. On one memorable morning at the 3-Bar, the temperature before the sun rose was 17°F, and there was a light covering of snow that capped the saguaros and made them seem to shiver. Peccaries are typical tropical mammals. Because they have no heat-retaining wooly undercoat, peccaries quickly begin to expend extra energy to maintain a constant body temperature when they are exposed to cold. As a result, in the winter they are diurnal, moving and feeding during the day. Huddling together on winter nights is essential if the animals are to stay alive. (As summer nears, peccaries become increasingly nocturnal, moving and feeding at night and resting in a shaded bed-ground throughout the day.)

One typical winter morning, I arrived at a vantage point above a herd's bed-ground before sunrise and before the animals were up. Rustling amid the turbinella oaks began as the sun appeared, and soon stretching, yawning, and shaking animals drifted into view. There was a concentrated bout of mutual rubbing between herd members, then the animals began to move in a rough single file from the bed-ground. They traveled only a short distance until, reaching a sunny spot, they began to feed.

During the winter much of the highly nutritious food on which peccaries usually depend, such as acorns, bulbs, mesquite beans, and cactus fruit, is unavailable, and for several months the animals may subsist al-

most entirely on prickly pear cactus. Lyle Sowls, leader of the Arizona Cooperative Wildlife Research Unit, has shown that captive peccaries can survive for several months on prickly pear alone but that they eventually deteriorate on such a diet. The plant is important for the animals because it sustains them through the lean winter period. The pads, or cladophylls, of the prickly pear cactus, with their long spikes and tufts of spines, do not seem to be inviting food items, yet the peccaries, with apparent disregard for the spines, attack them with impunity. Occasionally, individuals will worry a pod loose from the plant, then paw at it as if to break off some spines. More frequently, they simply approach a plant and bite directly into it.

In the herd I was observing, feeding animals remained close together and often several individuals fed side by side from the same plant. Occasionally, squabbles broke out when one animal approached and began to feed next to another, but more frequently the animals simply fed together peaceably. In many instances, two animals were able to approach and feed so close to each other that their snouts almost touched. Juveniles, in particular, were able to approach adults and feed mouth to mouth with them. Juveniles even snatched food dangling out of the mouth of an adult without suffering retribution.

After a bout of intensive feeding, the herd began to travel rapidly in a particular direction, with animals feeding in a more choosy and desultory fashion. Moving and feeding continued until between 10:30 and 11:00 A.M., by which time the herd had traveled approximately a half mile from where it started and was nearing another bed-ground. As is often the case, this site was surrounded by a radiating network of trails, and when the animals encountered a trail, they quickly moved onto it and walked steadily toward the bed-ground.

As the animals entered the bed-ground a striking event took place: all herd members began to play in a wild and comic manner. Such play bouts are frequently started by juveniles, but most adults participate in them. Mutual chasing around a bush and one peccary flopping on the ground to mock bite with a partner standing over it were particularly common. My favorite play action involved one animal running full-tilt downhill toward another lying flopped on its back; the two would clamp jaws, and the running peccary's momentum would carry it sailing over the other, rotating in a slow arc, like a diver in layout position, until it crashed heavily on its side. As is true of their social behavior in general, peccaries show great behavioral diversity while playing. Play bouts lasted about fifteen minutes, and juveniles tended to play longer than adults. Eventually, all animals reclined close together, many lying side by side.

The herd rested for several hours. Individuals got up and fed briefly or changed places to recline next to another herd member or moved in and out of the sun to keep comfortable. Much quiet, amicable behavior, including sniffing, nuzzling, and lying in close contact, could be observed

Jerry Day

Two peccaries perform a "mutual rub." Each rubs its head over the other's dorsal gland. The scent of the gland's oily secretion may aid in judging distance between herd members.

Jerry Day

Prickly pear cactus is an important winter food. The spines of the plant do not deter the peccaries, which simply bite into the pads. Two or more peccaries commonly feed together without dispute.

during this time. When the animals began to move again, they did so rather suddenly. More feeding followed, with the animals moving rapidly. As darkness fell, the herd was close to the bed-ground where it would spend the night.

A day in the life of an individual peccary is thus dominated by feeding, slow movement, and resting, with other animals always close at hand. The day is punctuated by brief feeding squabbles, mutual rubs, and most conspicuously, by play. The single most revealing and important fact about peccary social organization is that the average distance between animals is about ten feet, or three body lengths. Individuals are born into a herd and are literally surrounded by familiar animals throughout their lives. By this criterion alone, peccaries are more social than most other ungulates. Moreover, as I have intimated, they also display a level of cooperation that makes them unique among the hoofed mammals.

Cooperation takes several forms. First, there is some degree of cooperative feeding, or food sharing. This practice may occur between adults, but it is especially prevalent between adults and juveniles. All juveniles are apparently given carte blanche by all adults, and juveniles are not in the least hesitant to use their special status, often aggressively driving an adult from a food source, as well as snatching food from an adult's mouth. Adults could easily dominate juveniles in these encounters, but they do not. This social convention is probably important for juveniles in several ways: it provides for mostly positive social interactions between juveniles and their future peers; it gives juveniles access to high-quality foods; and it probably teaches them what types of plants should be eaten. All adults extend these favors toward *all* young; nonparents are as tolerant as parents.

Feeding interactions illustrate a more general phenomenon: adults are tolerant of juveniles in all respects. In bed-grounds, juveniles clamber over the reclined herd and try to wedge themselves between adults; on trails, they are often able to shoulder adults aside. In one typical instance, two small infants stood beneath an adult's chin and repeatedly snapped at its mouth as it tried to feed. The adult was forced to elevate its snout in order to chew, and in this position it began to walk forward. The juveniles darted between its front legs and caused it to stumble. There was no retribution.

Adults also act cooperatively to protect juveniles from predators. The canine teeth of peccaries in both sexes are long, robust, and self-sharpening since the back of the bottom canines slide against the front faces of the teeth on top. Adult peccaries do not tolerate coyotes or bobcats. They quickly drive them away, while often ushering juveniles in another direction. The response of herds to humans, and probably to large predators such as bears or mountain lions, is different. Here there is no attempt at defense; the animals simply run away. If the disturbance is mild enough (as when the herd picks up the scent of a distant human observer), there is a well-organized retreat, with one or two adults

Jerry Day

Rubbing its dorsal gland against a rock face, this peccary is scent-marking a boundary site of its herd's home range. Neighboring herds seldom mark over each other's scent deposits.

in the lead, followed in single file by the juveniles, then the rest of the adults. If the disturbance is more immediate (as when the observer blunders into the midst of a herd), the animals tend to scatter in all directions in an every-peccary-for-itself manner. This set of strategies makes sense. If defense or organized retreat is possible, it is carried out. If the danger is so large and imminent that defense would be futile, the herd's scattering may tend to confuse a predator. It also would tend to draw attention away from the helpless juveniles, which in these situations seek some kind of cover and remain motionless. Herds quickly regroup after a disturbance, individuals using the low grunt to locate one another.

A third form of mutual assistance is cooperative nursing. Unlike females in most ungulate species, peccary females will allow young other than their own to nurse. Juveniles approach from the rear and suckle while the female stands. Females do not turn around to check the identity of these young, and it seems that most young are able to nurse from most females that have milk. On several occasions in herds that had many new young, there was a snapping, jostling horde of hungry young at the rear end of one female. There were obvious injustices—with larger young pushing smaller ones aside—but the nursing females continued to munch cactus complacently, as if the storms behind them did not exist. Milk production in mammals is an energetically expensive business, and females of most species usually make sure that they give milk only to their own young. In many ungulates, females will not tolerate an alien juvenile in their vicinity while they are nursing. I thus found it striking that peccary females seem to distribute milk indiscriminately.

Peccaries are also unusual mammals in that males do not compete actively for mating rights. When a female is in estrus, there may be a slight increase in aggressive behavior, but more often than not, pairs court and mate with other males quite close by. On one occasion I saw a female mate with one male, then turn and court and mate with another while the first stood idly by. I found it curious that males seem to give up individual reproductive success. The most likely explanation is that the males in a herd are so closely related to each other that for any individual the difference in real reproductive success between a female producing his offspring or the offspring of another male is so slight that it is not worth fighting about. It is not known if inbreeding reveals deleterious recessive genes in peccaries or if there are social mechanisms that preclude matings between very closely related individuals.

The low level of competition between males is also reflected by the lack of sexual dimorphism in peccaries. Males and females are equal in body size, and both sexes have large, sharp canine teeth. In other species that have mating systems in which males fight for access to females, males are usually much larger than females and tend to have large, conspicuous fighting and display structures, such as the horns and antlers in many other ungulates. The lack of sexual dimorphism in peccaries suggests to me that the species has had a substantial evolutionary history of reduced male–male competition.

The collared peccary is thus, by many measures, a highly social beast. The animals in a herd are cohesive and possess two specialized ways of maintaining close contact (the mutual rub and the low grunt). There is cooperative feeding, mutual tolerance of young by all adults, regular play that involves all herd members, cooperative nursing, and reduced male–male competition. The species is close to one extreme of the spectrum of mammalian sociality and was indeed appropriate for my study of behavioral development.

The development of behavior and the nature of early experience in peccaries is another story in itself. The gist of what I found is that in development, as in adult social behavior, peccaries are different from most other mammals. In other highly social species, juveniles interact amicably with each other and in this way probably form the bonds that draw them together as adults. Peccary juveniles barely interact with each other for the first seven months of life and when they do interact, it is likely to be in a fight over access to food or a female's teat. Yet these juveniles eventually grow up to become amicable, cohesive, and cooperative adults. Adult tolerance of juveniles is probably vital in this species, and juveniles seem to be brought into the social group via their interactions with adults, not their interactions with each other. There are intricacies in this process that I will try to sort out in future field seasons. □

The 1981 Rolex Awards For Outstanding Enterprise

The Rolex Awards for Enterprise is an international program to provide financial help and special encouragement for individuals whose projects have broken new ground in their chosen fields. These projects capture that spirit of enterprise which has been such a characteristic of the development of the Rolex watch. Here are the five award winners of 1981 with a resume of their projects.

A Blueprint for Disarmament — Seymour Melman

If global disarmament ever is to be achieved, one vital step in the process will be to convert industrial economics from military to civilian work. Seymour Melman, an American Professor of Industrial Engineering, has been exploring myriad technical, economic and organizational changes required to make such conversions work.

As industrial economics vary widely, Professor Melman is formulating three representative models for conversion: the U.S.A. and Western Europe, the Socialist countries, and the less-developed countries.

His 1981 Rolex Award for Enterprise will enable Professor Melman to develop his blueprints for conversion.

To Save the Snow Leopard — Rodney Jackson

In the snow-covered Nepalese Himalayas lives the elusive, endangered snow leopard.

Mr. Rodney Jackson, a wildlife biologist, plans to capture live several specimens of these magnificent creatures and collar them with radio transmitters. Very little is known about the snow leopard, but we do know that it faces almost certain extinction as man encroaches upon its habitat.

Mr. Jackson's 1981 Rolex Award for Enterprise will expand our knowledge of the snow leopard and its environment and help save a beautiful species from extinction.

Preserving Mexican Folk Music — Eduardo Llerenas

The culture of Mexican folk music is one of the richest in the world.

However, due to the influence of TV, radio and the record player, it is a culture fast disappearing.

With two companions, Mr. Eduardo Llerenas has made over eighty trips into the remotest parts of Mexico in order to record, compare and preserve the country's traditional songs.

When completed, the work of Mr. Llerenas will provide an accurate and lively record of the folk music of Mexico.

His 1981 Rolex Award for Enterprise will help Mr. Llerenas to complete this valuable undertaking.

Re-fertilizing the Earth — Andre Martin

All over the world, vast tracts of fire-damaged land lie waste. To return land such as this to its original fertility is the aim Andre Martin has set himself. The undergrowth, brushwood and scrub, the only things which will grow on such land, are cleared and converted into an organically rich compost.

In a successful experiment in France, twenty previously desolate acres have been returned to successful cultivation using this method.

His 1981 Rolex Award for Enterprise is reward for Andre Martin's truly fertile imagination.

Let the Sperm Whale Live — Milan Mirkovic

Mr. Milan Mirkovic has devised a novel irrigation method for the growing of the jojoba bush. The jojoba nut contains an oil which is almost identical in properties to sperm whale oil and therefore could become a commercial alternative to sperm whale slaughter.

However, it is only Mr. Mirkovic's use of containers filled with earth and a water absorbent polymer (it holds 1,000 times its own weight of water, thus dramatically reducing the cost of irrigation) which may make the cultivation of the jojoba a commercial possibility. Mr. Mirkovic's 1981 Rolex Award for Enterprise should help in saving the sperm whale.

Each of these five winners has received 50,000 Swiss francs as a contribution to the fulfillment of his work. Each has also received a specially inscribed Rolex Oyster as a tribute.

The 1981 Rolex Awards for Enterprise: Help and encouragement to those who have demonstrated truly outstanding enterprise.

SCOTTISH HIGHLANDS. Wildlife trips weekly April-October. Other wildlife destinations include Shetland, Orkney, Iceland, Tanzania, Canary Islands, Nepal, Texas, Arizona & California, and Alaska. Also backpacking and trekking in Nepal, Peru, Bhutan and Scottish Highlands. Expert leadership. Write: McGregor Travel, 33 Lewis Street, Greenwich, Connecticut 06830, or call: (800) 243-5330

VACATIONS IN NATURAL HISTORY for singles, couples, families—sailing—trekking—birding—photography—research. Blue Sky Adventures, Dept. NH5, Oak Ridge, NY 07438

RATES AND STYLE INFORMATION

$1.75 per word, 16 word ($28) minimum. *Display classified* is $150 per inch. All advertisements must be prepaid. Rates are not structured for agency or frequency discounts. All advertisements are accepted at NATURAL HISTORY's discretion. Send check/money order payable to NATURAL HISTORY to: The Market, NATURAL HISTORY Magazine, Central Park West at 79th St., New York, NY 10024. Please include your personal address and telephone number, issue preferred, and suggested heading. Deadline—8th of month, two months prior to cover date (the January issue closes Nov. 8). Camera-ready art is required for display ads. A tearsheet or copy of the page with your ad will be sent upon publication.

Box numbers, telephone numbers, and hyphenated words count as two words; abbreviations and zip codes as one word each. All states are shown in two-letter code followed by zip, then telephone (with area code), if desired. Occasionally, slight editing is required for clarity. Thank you!

Searching for Dim Companions

Astronomers use a variety of techniques to find the less luminous partners in double star systems

by James W. Christy

The major characteristic of the universe is that it organizes matter into very small packages, thus producing its characteristic appearance in visible light of bright points on a black background. The organizing force is gravity. Gravity has condensed matter from the vastness of space into galaxies, stars, planets, comets, and even smaller bodies. Many of these small bodies are relatively dark objects. Consequently, in addition to the bright points on the black background, there are even more dark points about which we know little. Some are dead stars, notably the postulated black holes. Fortunately, it is possible that black holes, black dwarfs (stars too small to ignite and shine as a result of nuclear reactions), and planets may occur primarily in the presence of visible stars. This is demonstrated in the existence of the planets around our sun and in the existence of double stars, or binary systems, where very small and dim stars sometimes orbit brighter ones. Many binary systems consist of stars of nearly equal brightness, but it is the dim companions that are especially interesting. The frequency of systems with small companions relates directly to our understanding of the formation processes of stars and, furthermore, to the expected frequency of occurrence of systems with extremely small companions, such as planets.

That dim stars are often paired with brighter ones at least eliminates the frustration of searching the entire sky, 535 billion square seconds of arc, when looking for nearly invisible objects. (An arc second is a measurement of how large an object appears to the viewer. It is a small unit that depends on the size and distance of the object. One arc second, for example, is about one eighteen-hundredth of the diameter of the full moon as seen from the earth.) However, this pairing means that many of the objects in the universe may lie very close to other stars, inside the atmospherically caused fuzziness that broadens images seen through earthbound telescopes. The size of such images is normally larger than one arc second. At the distances of most stars, such fuzziness would easily obscure an entire solar system. One might conclude that there is very little one can do to obtain information about these less luminous objects from ground observations, but the fact is that during the last century astronomers have been amazingly successful, using a combination of techniques for pulling information out of fuzzy images. Because the success of these techniques depends primarily on the distance of the systems from the earth, let us divide them into three separate distance groups. First, there are those nearer than the bright star Vega, in the constellation Lyra, approximately 27 light-years from the earth; second, those farther than Vega and out as far as the Pleiades star cluster, 410 light-years away; and third, those beyond the Pleiades and out as far as the center of our galaxy, 30,000 light-years away.

The sun is just eight light-minutes from the earth, and so Vega lies about the same distance from the sun as from the earth—twenty-seven light-years. Nearer than Vega there are about two hundred known stars, most of which are smaller and dimmer than the sun. Probably many smaller and even dimmer stars remain to be dis-

covered. Only twenty of the nearby stars are visible to the eye without a telescope since fully 90 percent of all nearby stars are very dim dwarfs. Of the twenty brightest nearby stars, we have excellent knowledge because their brightness permits application of all of the techniques at our disposal.

For example, the angular diameter of Vega has been shown by means of interferometry measurement to have a value of 0.0037 arc seconds, about three times that which the sun would have if seen from the same distance. Interferometry is a technique used for the measurement of wavelengths of light in order to determine the distances between stars and the diameters of stars. Interferometry takes advantage of the wave nature of light. That is, light waves from two adjacent points, say, two stars or two points at opposite ends of a star's diameter, will interfere with one another, causing light and dark fringes to appear in the image when an interferometer is properly adjusted. The presence or the absence of fringes as the instrument is adjusted provides a measurement of the diameter of the star or reveals the presence of a companion star. A stellar companion to Vega of similar brightness is easily excluded by such measurements, which also show that Vega has no fainter companions down to approximately one-tenth of its brightness.

The existence of a companion of less than this brightness would be revealed by a perturbation. A perturbation is a wobble in the motion of a star across the sky. Because binary stars revolve in orbits around their common center of mass, a faint companion of one-tenth the mass of Vega would cause Vega to wobble with a motion of one-tenth of the apparent distance between the two stars and with a period the same as their mutual orbital period. Because we can detect wobbles as small as 0.01 arc second by measuring photographs of bright stars taken over the years, a faint companion of one-tenth Vega's mass would be detectable if its distance from Vega were larger than 0.1 arc second. That is equivalent to 0.8 astronomical units at Vega's distance from the earth (one astronomical unit equals the distance between the sun and the earth). If the companion had a mass one-hundredth that of Vega's, its separation would have to be larger than 1.0 arc second, or eight astronomical units, to be detectable, and its orbital period would be about fourteen years. An orbital period longer than this presents an observing problem because at least two orbital periods of observation are needed to confirm the perturbation. For longer periods the companion would at times be outside the fuzzy image of Vega, and direct detection would be possible by visual examination or by photography.

In addition to the wobbling motion caused by a stellar companion, there exists the changing orbital velocity of each member of the pair. The ratio of the velocities of the two members of the binary star, orbiting their common center of mass, will be the inverse of the ratio of their respective masses, with the less massive star having the greater velocity. If the mass of one of the stars is one-tenth that of the other, then the less massive star will have an orbital velocity ten times that of the more massive one. If an astronomer obtains several spectra of

Enter the world of Questers nature tours.

When you travel with Questers, you have the advantage of our knowledge of the travel world And our experience of the natural world We are travel professionals And our only tour program is Worldwide Nature Tours

Under the leadership of an accompanying naturalist, we search out the plants and animals, birds and flowers rain forests, mountains, and tundra .seashores, lakes, and swamps of the regions we explore At the same time, we include the more usual attractions in touring—the cities, archaeological sites, and people.

The current Directory of Worldwide Nature Tours describes 29 tours varying from 9 to 36 days and going to virtually every part of the world Included are The Amazon, Peru, Patagonia, Galapagos, Hawaii, Alaska, Death Valley, Everglades, Ladakh, Sri Lanka, Iceland, Scotland, Greece, Australia, and New Zealand Tour parties are small, the pace leisurely, and itineraries unusual

Call or write Questers or see your Travel Agent today for your free copy of the Directory of Worldwide Nature Tours.

the light from such a binary system, shifts in the lines in the spectra may be measurable. These Doppler shifts measure the radial velocity of the brighter of the two stars in the system (a star in a binary pair with, say, one-tenth the mass of its partner will contribute less than one percent of the light of a spectrum). The radial velocity is the component of the star's motion that is directly toward or away from the earth. If we happen to be looking at the system so that the stars are moving at right angles to our line of vision, then their radial velocities will always be zero, and their orbital motions will be undetectable in the spectrum. For most binary systems, the stars are not moving at right angles to our line of vision, however, so that some radial velocity due to orbital motion exists and can be measured if it is large enough and if the star is bright enough so that its spectrum can be obtained with an exposure time that is much less than the orbital period.

In the case of Vega, if a one-tenth mass companion at a distance of 0.8 astronomical units existed, the velocity variation of Vega would be about 3.5 miles per second in five months time. This velocity variation is just detectable, which tells us that in such a case the method is useful for separations of less than 0.1 arc second, because the velocities become larger with decreasing orbital size for any pair of objects. In neither the positional nor the radial velocity observations for Vega itself has a perturbation been detected. Thus, the existence of a companion star with a mass larger than one-tenth that of Vega is virtually excluded by present observations. This does not hold true for all of the other bright stars nearer the earth than Vega, where the techniques of visual examination, interferometry, perturbation measurements, and measurements of radial velocity perturbations have resulted in the detection of numerous stellar companions.

However, most of the nearby stars are not visible to the unaided eye. In fact, the faintest known of these objects are one million times fainter than the brightest 10 percent of the nearby stars. Fortunately, the method of perturbation measurements still works well for these faint stars, although the other methods fail when applied to stars of fainter apparent magnitude. Photographic exposures of up to several hours are required for the faintest stars known, but the positional measurements possible with such photographs are nearly as accurate as those of the very short exposures for stars one million times brighter. Furthermore, the faintest star known, Van Biesbroeck's Star in the constellation Aquila, has a mass approximately one percent that of Vega. A hypothetical companion of Van Biesbroeck's Star would thus produce a wobble of Van Biesbroeck's Star 100 times that produced by a similar companion of Vega. Using the above techniques during the rest of this century, astronomers should find all of the stellar companions of stars nearer than Vega. Most have been found already.

Van Biesbroeck's Star is the least massive star known, with a mass about thirty times that of Jupiter. The theory of stellar interiors indicates that a star with a mass smaller than this will not undergo nuclear burning in its interior, and thus stars of masses from roughly three to thirty times that of Jupiter are termed "black dwarfs." Although they may glow from internal heat as do Jupiter and Saturn (in infrared radiation), they will be much fainter than true stars, such as the sun, which shine as a result of nuclear energy production.

The problem of detecting black dwarfs and planets is not easily solved. When orbiting other stars, planets such as the four giant planets of our solar system—Jupiter, Saturn, Uranus, and Neptune—can be detected by the perturbation method only if the star they are orbiting is one of the nearest to our solar system and if the star has a small mass. However, with existing equipment even these conditions bring the planet only to the fringe of detectability. Fortunately, instrumentation now in the development stage will be capable of greater precision. Also, the launching into orbit of the Space Telescope in 1985 should provide an increase of more than tenfold in our capacity to detect small masses. Thus the opportunity exists to detect some black dwarfs and planets around nearby stars, and perhaps by the year 2000 to at least estimate the number of black dwarfs and planets nearer than Vega.

Let us now look at a more distant region of space, beyond Vega's distance of 27 light-years and extending as far as the Pleiades star cluster, 410 light-years from the earth, or

about fifteen times as distant as Vega. The number of stars out there should increase approximately in proportion to the volume of the region, which is $15 \times 15 \times 15$, or 3,375, times greater than the volume of the region between the earth and Vega. If we multiply $15 \times 15 \times 15$ by 200, for the known stars out as far as Vega, we get 675,000 or more stars that may be nearer than the Pleiades. This region of space, although only a tiny piece of our Milky Way galaxy, is critical to astronomy because in this region many types of stars exist that do not happen to be found nearer to earth than Vega. And in this region, relatively nearby within a 410-light-year radius, astronomers can calibrate the luminosity, or true brightness, of the stars because direct distance determination, which is impossible at greater distances, is feasible. At greater distances the brightness of the stars is generally used to make crude estimates of their distances. This is done by means of the very critical luminosity calibrations in the Pleiades and nearer.

At distances between that of Vega and that of the Pleiades, we can do little to detect black dwarfs and planets because the size of their wobbles decreases in proportion to their distance. The discovery of stellar companions is still possible, however, although more difficult. But the number of stars to investigate for companions is very large, and most of the binary stars known (roughly 50,000) have been discovered in this region by direct visual examination of the image through the telescope. An experienced visual observer can detect stars separated by only one-tenth of an arc second by waiting patiently for moments of excellent viewing. Superb eyesight and telescope quality are required for this demanding task, as well as unusual endurance on long, cold nights.

Radial velocity perturbations do not decrease with distance, and therefore, for sufficiently luminous stars, the method of velocity perturbations retains its value out to great distances. However, the brightness of a star decreases with the square of its distance. If Vega were moved fifteen times farther away, to the distance of the Pleiades, it would be 15×15, or 225, times fainter, and the exposure required to obtain its spectrum would be 225 times longer, or roughly an hour. In principle, we have the capacity to discover in this region all companions that are of a luminosity brighter than that of our sun. In practice, there are too many such objects, and we must be somewhat selective.

Beyond the distance of the Pleiades lies 99.99 percent of our galaxy and roughly 100 billion other galaxies. All of the universe must be interpreted in terms of what is observed in the Pleiades and nearer because of the blurred images and faintness that limit most observations beyond the Pleiades. The number of stars becomes huge, in the hundreds of billions within our galaxy alone. In such an enormous sample of stars, another detection technique becomes possible. Many binary star systems will be found oriented in such a way that their orbital plane lies nearly exactly in the line of sight. The two stars of a binary system will pass in front of each other producing eclipses at intervals of one-half of their orbital period. The brightness variation makes such "eclipsing binaries" show up on repeated photographs. Once the brightness changes of an eclipsing binary system are detected, detailed study can yield a rough idea of the shapes and surfaces of both stars. If the stars are bright and their radial velocities are obtainable, astronomers can measure with precision the diameters of the stars in the pair by determining the lengths of the two eclipses in the orbital period. Thus even at distances of thousands of light-years, for a few select stars we can measure sizes down to one-millionth of the image diameter and, in a fashion, see two stars.

In our solar system a similar technique will yield a special surprise in the case of the planet Pluto and its moon Charon. A few years from now, Pluto's slow orbital motion around the sun will line up its orbital plane and that of Charon in such a fashion that seen from the earth each object will alternately eclipse the other. For some five subsequent years this system will behave like an eclipsing binary, with an orbital period of about six days. Thus a brightness mapping of the surfaces of both bodies will be obtainable, and we will at last be able to discern the details of Pluto and Charon despite their distance from the earth.

James W. Christy is an astronomer at the U.S. Naval Observatory in Washington, D.C. He is credited with discovering Pluto's satellite Charon in 1978.

Presenting the Arctic

Magnificent. Dramatically different. Seen by few.

A land of delicate wildflowers and vast rolling tundra. The home of caribou, polar bear, sea mammals, migratory birds, Arctic char. And the land of the midnight sun.

Meet and visit the Inuit ...great hunters, skilled craftsmen, a people in harmony with this land.

Better Than Jogging

NordicTrack
Jarless Total Body Cardiovascular Exerciser Duplicates X-C Skiing for the Best Motion in Fitness

This revolutionary new exerciser duplicates the smooth, rhythmic, total body motion of X-C skiing for the most effective cardiovascular exercise obtainable. Uniformly exercises more muscles than any other exercise device. Makes high heart rates easy to obtain and keeps more muscles in tone. Also highly effective for weight reduction.

Completely jarless natural motion does not cause joint and back problems as in jogging or running. Arm and leg resistances are separately adjustable for maximum effectiveness. The NordicTrack uses no motors and folds compactly for convenience. Used in homes, businesses, and institutions. Our customers include Xerox Corporation, US Army, Penn State U and the YMCA.

Celestial Events

by Thomas D. Nicholson

The Moon Phases in June are new on the 2nd, first-quarter on the 9th, full on the 17th, and last-quarter on the 24th. The next new moon is on July 1, first-quarter on July 8, and full on July 16.

The early crescent moon should appear by the 4th or 5th below the twin stars of Gemini, Castor and Pollux. By the evening of the 7th, the moon is entering Leo, and the bright star near it is Regulus. The first-quarter moon of June 9 is entering Virgo. The bright objects near it on the 9th and 10th are Jupiter and Saturn and on the 11th, Spica, Virgo's brightest star. The waxing gibbous moon passes above Antares, the bright red star of Scorpius, on June 15. Full moon of June 17 is very close to the winter solstice, in Sagittarius, and the waning gibbous moon moves through Capricornus on June 20 and 21.

The first glimpse of the crescent moon in July should be on the 5th, with Regulus nearby. Entering Virgo on July 7, the moon passes near Jupiter and Saturn that night and is near Spica on the 8th. The full moon of July 16 is in Sagittarius again, and a partial lunar eclipse (visible in North America) occurs July 16–17.

Stars and Planets At one time or another in June, all the planets but Mars are evening stars (Mercury is one until the 21st and Neptune after the 14th), but only Jupiter and Saturn are bright enough and sufficiently well placed for viewing. Uranus, Neptune, and Pluto are too dim to be seen and Mercury, Venus, and even Mars, although it is a morning star, are too close to the sun's position.

Jupiter and Saturn are very well placed, however, high in the south–southwest at dusk. In their position near the western edge of Virgo, they have no competition from nearby bright stars. They stand out because of Jupiter's brilliance (once Venus sets, Jupiter is the brightest object visible, except for the moon) and because of Saturn's proximity to the brighter planet. During the early evening, they move west together, trailed by Spica, the brightest star of Virgo. Be sure to look on the nights of June 9, 10, and 11 when the moon is passing through their part of the sky.

Jupiter and Saturn (after the 5th) have resumed direct, easterly motion through the stars and both will move slowly closer to Spica, while Jupiter in turn moves closer to Saturn. Jupiter, the brighter of the two, is to the right all month, but the distance between them diminishes markedly, and Jupiter will slide slowly to Saturn's south (below it). In late July, Jupiter will pass to the left (east) of Saturn, the third and last of the three conjunctions that have occurred since January 14.

Venus and Mercury may be glimpsed as evening stars early in June, low in the west during twilight. Venus, which is very bright, will be the easier to see and viewing it improves during the month. Mercury will be better placed at the beginning of June, but it is not very bright and moves closer to the sun rather quickly.

Mars, the only visible planet in the morning, rises just before dawn, north of the Hyades in Taurus. However, it is a dim, inconspicuous object and will remain so for many months.

The sun spends most of June in the constellation Taurus, moving into Gemini just before reaching the summer solstice. Mercury is in Gemini all month until it moves westerly into Taurus for a brief period in late June and early July. Venus moves out of Taurus into Gemini in early June and into Cancer before the end of the month. Mars is in Taurus all month, Jupiter and Saturn are in Virgo near the autumnal equinox, Uranus is in Libra (close to Scorpius), Neptune is in Ophiuchus (near Sagittarius and the position of Kepler's Nova of 1604), and Pluto is in the southwest corner of Boötes, near Virgo.

June 1–2: Perigee moon (nearest the earth) occurs 21 hours before the new moon, adding its force to the usu-

ally stronger spring tides. Look for higher tides on the 2nd.

June 3: If the western sky is clear enough, you might see the very slender crescent moon (only 36 hours old) to the left and above Venus. Mercury is closer to the moon, to its right.

June 5: Saturn is stationary, relative to the stars, and resumes its normal direct (easterly) motion.

June 9: Mercury begins its retrograde (westerly) motion, rapidly approaching the sun's position as it moves between the earth and the sun.

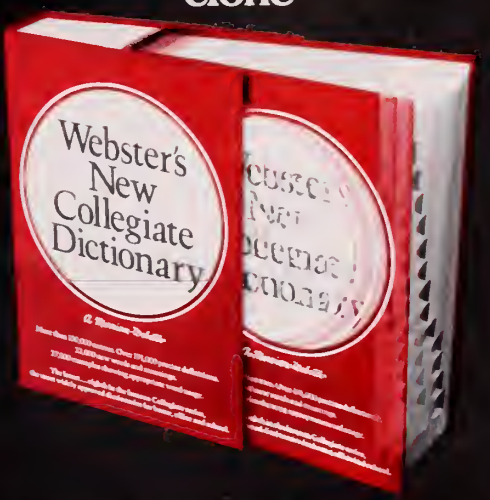
June 9–11: Be sure to watch the moon move past Jupiter and Saturn (from the 9th to the 10th), and then past Spica (on the 11th).

June 13: The moon is at apogee (farthest from the earth).

June 21: The sun arrives at the summer solstice at 6:45 A.M., EST, and summer begins in the Northern Hemisphere. The sun's path across the sky today is the highest and longest of the year, making the 21st the longest day. However, as sunrise–sunset tables will verify, this is *not* the date of the earliest sunrise and latest sunset. Earliest sunrise occurs about June 14 and latest sunset about June 27, but the dates vary with latitude.

June 24–25: The last-quarter moon rises about midnight on the 24th. If you are curious about the position of the vernal equinox, it is just above the moon's position in tonight's sky.

June 29–30: Another perigee moon occurs on the 29th. The star nearest the crescent moon at dawn is Mars.



July 3: Mercury resumes direct (easterly) motion. The earth is farthest from the sun (aphelion), 152,103,000 kilometers (94,513,000 miles) distant.

July 7–8: The moon again passes Jupiter and Saturn (on the 7th) and Spica (on the 8th).

July 14: Mercury is at greatest elongation from the sun in the morning sky, but not well placed for viewing.

July 16–17: A partial lunar eclipse occurs tonight, visible in North America from 10:25 P.M. until 1:10 A.M., EST. (Adjust for other time zones.)

Seven
beautiful ways
to keep warm

At last — a superbly efficient woodburning stove beautiful enough for your home. And now in your choice of seven decorator tile colors!

The WESO Ceramic Tile Stove employs both convection and radiant heat to surround you with gentle, all-over warmth. The fire burns all night without tending — and when the coals have finally died, the tiles continue releasing heat into your rooms.

The WESO is built to burn both wood or coal. As you will see in our color literature, in appearance it is nothing less than breathtaking.

All WESO stoves have been tested to UL standard 1482

Plus
a new coal-
burning stove

A handsome enamelled cast iron heater from WESO. Burns cleanly and odor-free up to 24 hours on a loading

Why settle for any stove that offers any less than these 10 important features?

1. Tiles are safer to touch than blistering metal. 2. Liquid expansion thermostat for precise heat control. 3. Firedoor window lets you view the flames 4. Suspended burning basket and shaker grate permit burning coal safely 5. Air-tight construction for long fire life 6. Ash pan for mess-free cleaning 7 Top grille lifts for cooking 8. All-night burn 9. Secondary air combustion system 10. Protective wrought-iron style front grille swings away at a touch.

Rush me your literature portfolio by first class mail, featuring the WESO in all seven tile colors, complete performance data, details on WESO's new coal stove, and current shipping schedule. Enclosed is $1 to help cover mailing costs.

The Wildest of All Wild Places

by Boyce Rensberger

SAND RIVERS, by Peter Matthiessen. *The Viking Press, $19.95; 213 pp., illus.*

The "real Africa" has probably always been more a state of mind than a place. If you grew up in America or Europe, the very word itself, spoken in awe—Africa—was enough to evoke images of a deep and mysterious continent, the wildest of all wild places. Whether the images were nurtured by Joseph Conrad or Ernest Hemingway or even Edgar Rice Burroughs, Africa was the farthest you could go from where you were. Africa was one of those places you hoped would always be there.

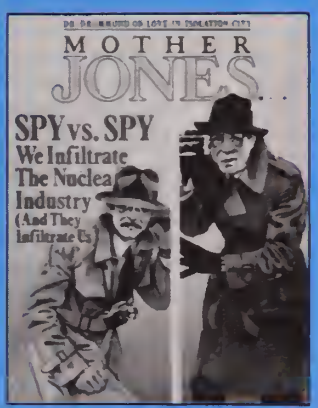
If you grew up in Africa, as did Brian Nicholson, a crusty old game warden who is the central figure in Peter Matthiessen's new book, *your* real Africa also lives in the mind. Not as a vicarious image but as a memory of the untrammeled natural spectacle that existed before Westernization pushed so far. It is the selective memory of one's youth mixed with the suspicion that things really were better in the old days. Your real Africa isn't there anymore.

Sand Rivers is the true story of a quest to recapture one piece of the real Africa, the little-known Selous Game Reserve in southern Tanzania. The Selous (pronounced Se-loo) is considered by some to be the greatest stronghold of large wild animals left on the earth. The book is a vivid and at times poetic diary of a foot safari, complete with ten barefoot porters, into a region where few have trod since the slavers and ivory caravans withdrew a century ago. The few Africans who lived there were evicted decades ago when colonial administrators established the reserve, and even then tsetse flies were keeping human numbers low.

Matthiessen's expedition—his first literary return to Africa since *The Tree Where Man Was Born*—took place in late 1979. As roads and Land-Rovers swarm over practically every other part of East Africa, Matthiessen and Nicholson walk into the unmapped wilderness. They take no compass but follow an old African game tracker named Goa, who probes the tall grass and miombo woodland with a drooping hand stretched ahead like a five-fingered dowsing rod. His yellowed eyes spot the dark elephant shadows moving in the distance, the lions prowling nearby, the startled rhino mother prepared to defend her calf. Bloody close calls in the past have taught Nicholson to carry a .458 "elephant gun," but Goa, wise in animal ways, always leads the silent file around the edge of the beast's perceived zone of safety.

Some 100,000 elephants have been estimated to live in the Selous, more than in all the rest of East Africa. There are also about 650,000 other large animals, including East Africa's largest populations of rhino, buffalo, hippo, crocodile, lion, and leopard, along with 350 species of birds and some 2,000 kinds of vascular plants.

Although the Selous Game Reserve has had some form of official protection for more than sixty years, it has been too remote from airports and tourist circuits to enjoy the fame or suffer the pressures of the kind experienced by the Serengeti National Park, some 400 miles to the northwest, or by Kenya's Amboseli, Tsavo, or Maasai Mara national parks. The Selous's only "use" has been as a reserve for very strictly limited sport hunting, an activity that threatened no species but did, until it was banned in 1973, bring Tanzania appreciable revenues.



The largest wildlife sanctuary in Africa, the Selous's 22,000 square miles make it three times the size of the vast Tsavo National Park and nearly four times as big as the Serengeti. Unlike most other wildlife sanctuaries, it is well watered by a network of broad, sand-lined rivers. Unlike other African reserves, the Selous covers an entire ecological unit, three of them in fact. This means that all the watersheds and migratory routes essential to its ecosystems lie within its boundaries.

And yet, as Matthiessen frequently intimates but never fully establishes, there are disturbing signs that the end may be near or, at least, the beginning of the end.

Before he quit in disgust in 1973 to become a charter pilot in Nairobi, Brian Nicholson had been in the Selous for twenty-three years, most of them as a game department warden. With the staff of crack game scouts that he trained, Nicholson watched carefully over the sanctuary he loved, battling poachers, working to expand the boundaries, and periodically burning the dry grasslands to—at least as he saw it—encourage the new growth that would continue to attract and hold the vast herds.

The Selous region had been made a game reserve as early as 1905 when the Germans were there. After World War I, when Tanganyika Territory, as it was called, passed into British hands, the reserve was maintained. In 1922, it was formally named after Frederick Courtenay Selous, a legendary British elephant hunter and explorer who once served as Theodore Roosevelt's "white hunter." In the 1930s a colorful young game ranger named C.J.P. Ionides came to the region and, with Selous as his hero, privately made it his life's work to protect and enlarge the reserve. With determination and, at times brutality, Ionides forced Africans out of the area

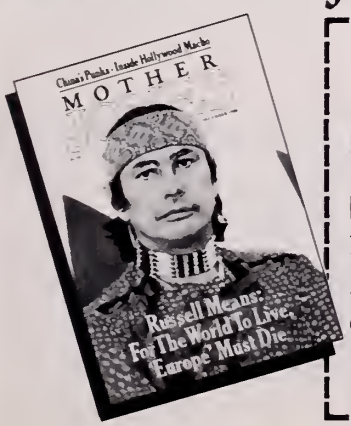
MOTHER JONES
MAKES NEW WAVES.

Our investigations have uncovered the dumping of hazardous products on foreign markets, a dangerous IUD, the deadly Pinto, Nestle's disastrous marketing of infant formula, and other scandals. MOTHER JONES gets results: legislation, recalls, and compensation for victims. We set a record for winning National Magazine Awards—three in our first four years of publishing. (That's the Pulitzer Prize of the magazine industry.)



MOTHER JONES
MAKES ENEMIES.

Some of the fattest cats in America have demanded everything from the revocation of our National Magazine Awards to denial of our mailing rights. We get under their skin—and they yell. We've been called "irresponsible, scabrous" (by an Agency for International Development official), a publisher of "lies, half-truths and distortions" (by a top Ford executive, about our article which made him recall two million Pintos), and "sleazy" (by Ronald Reagan's chief foreign policy advisor). We've never been called "dull."

MOTHER JONES
MAKES SENSE.

Whether our writers are taking on corporations, doctors, or Hollywood, you can expect MOTHER JONES to hit the target. Hard. Look at some recent stories: "Eating Our Hearts Out," on the politics of fat; "Running in Reverse," the report on a Ford transmission blunder which proved so severe that ten people died in the five months we were working on the story; "Filthy Lucre," the inside view of America's porn industry; "The Bendectin Cover-Up," a special investigation into the shocking history and government approval of a dangerous drug which has been taken by more than 30 million women. MOTHER JONES gives you special reports on up-to-the-minute topics like: medical malpractice and the alarming rise in Caesarean sections; the nuclear arms build-up and our race for extinction; the coming civil war in South Africa and the uneasy death of apartheid; the controversy raging over sex, violence and the meaning of pornography.

MOTHER JONES MAKES YOU AN OFFER.

I CAN'T REFUSE!

Sri Lanka's
PERAHERA
Festival of the August Moon

Join a special tour to Asia's most spectacular celebration honoring the Sacred Tooth Relic of the Buddha. A hundred elephants, dancers, drummers, temple bells, the cracking of whips, blazing torches that light a myriad gems create the stunning pageantry of the Kandy Perahera.

You also tour the countryside to see ancient cities in the interior, the hill country, coastal villages, spice gardens, tea estates and craft centers. Extensions to the mountain valley of Kashmir and to the temple cities of South India are available.

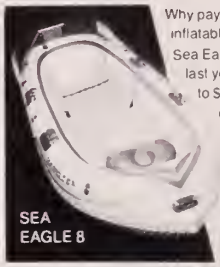
and persuaded the colonial government to enlarge the reserve.



Ionides left the Selous Game Reserve in 1954 to become a collector of rare animals, but Nicholson was there to carry on the tradition. In the early 1970s, however, the Tanzania Game Department was "Africanized," and many of the former colonial officials who had stayed on out of a dedication to wildlife were replaced with African civil servants who had little interest in the reserve. Funding and official support dwindled, and Nicholson found it impossible to maintain antipoaching patrols or to ward off economic and agricultural development programs that he felt threatened the sanctuary. One, for example, was a huge dam that is still under construction by the Norwegians in the eastern part of the Selous. Although the reservoir itself, planned for completion in about 1990, will do little harm, it is expected to create a whole fishing industry that will encourage new settlements. A new road linking the dam with distant towns is likely to "open up" the region to unprecedented agricultural development.

The colorful stories of Frederick Courtenay Selous, C.J.P. Ionides, and Brian Nicholson emerge in *Sand Rivers* as recollections and flashbacks illuminating the book's main narrative, the foot safari. In a way the safari was a publicity stunt dreamed up by Tom Arnold, a British M.P. who had recently become enchanted with Africa and who felt an international effort was needed to protect the Selous. It was his idea to have Matthiessen accompany Nicholson, the man who knew the Selous best, for a close inspection of the reserve in the most exciting way to see Africa—on foot. Matthiessen would do a book and Hugo van Lawick, the wildlife photographer, would go along to make pictures. The result is an undeniably persuasive combination.

Many who have never before heard of the Selous will probably finish the book eager to rally to the battle against poachers and rapacious development. But, worthy as the words and pictures are, *Sand Rivers* does not really make a very strong case that the Selous Game Reserve is truly in grave danger. Aside from the dam, most of the evidence is circumstantial or intuitive.

Many times, for example, Nicholson visits a part of the Selous where he had once seen great herds of elephant or buffalo and, this time, sees

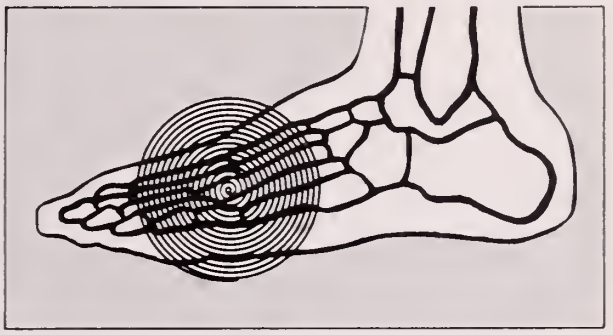
few or none. Matthiessen and Nicholson do come across some bones of killed elephants but they find nothing on the scale of poaching seen in Kenya in recent years. Nevertheless, Nicholson concludes that poachers must have decimated the herds. Matthiessen, on the other hand, observes that elephants are known to desert an area for their own reasons and to stay away for years. Although the hard evidence of truly major damage to wildlife is lacking, Matthiessen allows his eloquence to serve the more pessimistic view.



"We gazed about us for a little while at the vast wilderness all around," he writes of a visit to the reserve's Nandanga Mountain. "No sign of man, no marks or sounds, for hundreds of square miles. Even the ring-necked doves had fallen silent. There is a silence in the imminence of animals and also in the echo of their noise, but the dread silence is the one that rises from a wilderness from which all the wild animals have gone. In the dead still afternoon of the old continent, it seemed to me that the silence of Nandanga still had an imminence, a listening, a waiting in the air."

It is a cryptic remark, deliberately left cryptic, just as Matthiessen leaves many other thoughts in a state of ambivalence and observations open to several interpretations. Africa is like that.

Tanzania is one of the world's poorest countries and unquestionably must concentrate its resources on its own economic development. Building a dam in the Selous may even be the right thing for Tanzania to do. But the Selous is every acre the glorious wildlife spectacle that Matthiessen and van Lawick show it to be. And it is one of the last great wildernesses on earth. Compromises with economic development may destroy the real Africa in the minds of people like Brian Nicholson, but if *Sand Rivers* can rally enough international support for the Selous before it really is too late, it will have served not only Tanzania. It will have assured all the rest of us that our real Africa will always be there.

Boyce Rensberger, a science writer who lived in East Africa in 1973 and 1974, recently joined Science 81 *as a senior editor. His book,* The Cult of the Wild, *a study of attitudes toward wildlife conservation, was published in 1977.*

My Feet Were Killing Me...Until I Found Relief in Germany!

It was the European trip I had always dreamed about. I had the time and money to go where I wanted — see what I wanted. But I soon learned that money and time don't mean much when your feet hurt too much to walk. After a few days of sightseeing my feet were killing me.

Oh, I tried to keep going. In Paris I limped through Notre Dame and along the Champs-Elysées. And I went up in the Eiffel Tower although I can't honestly say I remember the view. My feet were so tired and sore my whole body ached. While everybody else was having a great time. I was in my hotel room. I didn't even feel like sitting in a sidewalk cafe.

The whole trip was like that until I got to Hamburg, Germany. There, by accident, I happened to hear about an *exciting breakthrough for anyone who suffers from sore, aching feet and legs.*

This wonderful invention was a custom-made foot support called Flexible Featherspring. When I got a pair and slipped them into my shoes *my pain disappeared almost instantly.* The flexible shock absorbing support they gave my feet was like cradling them on a cushion of air. I could walk, stand even run. The relief was truly a miracle.

And just one pair was all I needed. I learned that women also can wear them — even with sandals and open backed shoes. They're completely invisible.

Imagine how dumbfounded I was to discover that these miraculous devices were sold only in Europe. Right then I determined that I would share the miracle I discovered in Germany with my own countrymen.

In the last nine years over a quarter million Americans of all ages—many with foot problems far more severe than mine—have experienced this blessed relief for themselves.

Here's why Featherspring work for them and *why they can work for you.* These supports are like nothing you've ever seen before. They are custom formed and made for *your feet alone!* Unlike conventional devices, they actually imitate the youthful elastic support that Nature originally intended your feet to have.

Whatever your problem—corns, calluses, pain in the balls of your feet, burning nerve ends, painful ankles, old injuries, backaches or just generally sore, aching feet. Flexible Featherspring will bring you relief with every step you take or your money back.

Don't suffer pain and discomfort needlessly. If your feet hurt, the miracle of Germany can help you. Write for more detailed information. There is no obligation whatsoever. Just fill out the coupon below and mail it today. No salesman will call.

WHAT PEOPLE SAY ABOUT THE MIRACLE:

"Received my wife's Featherspring two days ago. They are super—neither of us can believe the results. She has had terrible feet for years; already no pain. Incidentally, her sore knee is much better . . . As a retired physician, this result is amazing." Dr. C.O.C. Tucson, Arizona.

"My husband felt a great relief and no more pain. They are truly an answer to our prayers. Only wish that he had heard of them twenty years ago." Mrs. F.S./Metairie, Louisiana.

"I have checked your corporation with (A Consumer Protection Agency), and received an excellent report." H.S.H./Louisville, Kentucky.

Carbon Forests (p. 32)

For a discussion of how excess atmospheric CO_2 may cause major climatic changes, see W.S. Broecker's "The Hazards of Coal Dependence" (*Natural History*, October 1977, pp. 8–19). In "The Biota and the World Carbon Budget" (*Science*, vol. 199, pp. 141–45), G.M. Woodwell et al. review the role of the terrestrial biota in the world carbon budget and conclude that the biota is not a sink for CO_2 but may be a source as large as, or larger than, the fossil-fuel source. Detailed methodology for reconstructing land-use history and changes in biomass and carbon is included in "Carbon Budget of the Southeastern U.S. Biota: Analysis of Historical Change in Trend from Source to Sink," by H.R. Delcourt and W.F. Harris (*Science*, vol. 210, pp. 321–23). "Fate of Fossil Fuel Carbon Dioxide and the Global Carbon Budget," by W.S. Broecker et al. (*Science*, vol. 206, pp. 409–18), evaluates various assumptions and models used to estimate the global carbon budget for the last twenty years and states that there is no compelling evidence establishing that the terrestrial biomass has decreased at a rate comparable to that of fossil-fuel combustion over the last two decades. G.M. Woodwell's "The Carbon Dioxide Question" (*Scientific American*, January 1978, pp. 34–43) examines the upward trend of CO_2 in the atmosphere caused by fossil-fuel combustion and forest destruction and speculates whether forests and oceans can store enough carbon to avert a major change in world climate. R. Allen's "The Impact of CO_2 on World Carbon" (*Environment*, December 1980, p. 6) warns that if present trends continue, a doubling of atmospheric carbon could occur sometime in the middle of the next century, raising average world temperature and initiating rapid, traumatic physical and biological changes.

Mississippi sawmill, 1893

Mississippi Department of Archives and History

Hausa Children (p. 44)

The daughter of a Hausa farmer and an Arabic teacher, Baba, a Muslim Hausa woman, agreed to dictate her autobiography to her friend M.F. Smith, wife of a social anthropologist studying in Nigeria. Baba's recollections, from the days before the British occupation up to the late 1940s, are recorded in *Baba of Karo* (London: Faber and Faber, 1954). N. Skinner's *Hausa Tales and Traditions* (London: Frank Cass and Co., 1969), the first of a three-volume compilation of Hausa folklore, history, and miscellania, is devoted to folklore. Comparing the religious and political sectors in Kano and tracing attitudes toward authority and community, J.N. Paden's *Religion and Political Culture in Kano* (Berkeley: University of California Press, 1973) argues that Kano's political culture has been deeply influenced by religious values and structure. W. Adamu provides a general summation of Hausa history in *The Hausa Factor in West African History* (Zaria: Ahmadu Bello University Press and Oxford University Press, 1978). P. Hill delineates the socioeconomic framework of a small Hausa village in *Rural Hausa* (Cambridge: Cambridge University Press, 1972). In the more recent *Population, Prosperity and Poverty* (Cambridge: Cambridge University Press, 1977), in a sense a companion volume to *Rural Hausa*, Hill reports on her fieldwork in an exceedingly densely populated locality of rural Hausaland, Dorayu, contrasting this area with the much less populated village of her previous study. Both books contain historical information and descriptions of Hausa life style. An analysis of how sex and age affect work, property rights, power, and order in different ethnographic contexts, *Sex and Age as Principles of Social Differentiation*, edited by J.S. La Fontaine (New York: Academic Press, 1979), includes E. Schildkrout's "Age and Gender in Hausa Society: Socio-Economic Roles of Children in Urban Kano" (pp. 109–

37). Schildkrout also interprets work roles in "Women's Work and Children's Work: Variation among Moslems in Kano," in *Social Anthropology of Work*, edited by S. Wallman (New York: Academic Press, 1979, pp. 69–85). Although it does not cover Hausa women, *Women in the Muslim World*, edited by L. Beck and N. Keddie (Cambridge: Harvard University Press, 1978), is useful for comparative purposes.

Shakespeare (p. 54)

S. Schoenbaum's article in this issue is adapted from his *Shakespeare: The Globe & the World* (New York: Folger Shakespeare Library and Oxford University Press, 1979), published as a catalog for a touring exhibition of the same name. Illustrated with rare materials from the Folger Shakespeare Library, the book's subjects range from the fauna and flora of Warwickshire to Shakespeare's years in Stratford and London. A. Gurr's *The Shakespearean Stage, 1574–1642* (Cambridge: Cambridge University Press, 1970) pictures Shakespearean society, drama, acting companies, theaters, and staging. For background on the Elizabethan era, see *The Horizon Book of the Elizabethan World*, by L.B. Smith (New York: American Heritage Publishing Co., 1967), a large, colorful book featuring a picture portfolio of the Elizabethan theater, and A.L. Rowse's more scholarly treatment, *The England of Elizabeth* (New York: Collier Books, 1966), an encyclopedic survey of that society's socioeconomic, political, and cultural structure. Rowse's *William Shakespeare* (New York: Harper and Row, 1963) and S. Schoenbaum's *William Shakespeare: A Compact Documentary Life* (New York: Oxford University Press, 1978) are two carefully researched biographies. Because of their age, some of the better books on Shakespeare and natural history are generally not available except to those with access to large or university libraries. Among these are E.S. Rohde's *Shakespeare's Wild Flowers: Fairy Lore, Gardens, Herbs, Gatherers of Simples and Bee Lore* (London: The Medici Society, 1935), a "poetical and historical" work that analyzes Shakespeare's references to natural history and features color plates of beautiful, rare watercolors; and *The Animal-Lore of Shakespeare's Time* (London: K. Paul, Trench and Co., 1883), which, according to author E. Phipson, brings together "in an accessible form waifs and strays of information, collected from various sources, relating to medieval natural history. . . ." *The Birds of Shakespeare* (Chicago: University of Chicago Press, 1965) is a reprint of J.E. Harting's *The Ornithology of Shakespeare Critically Examined, Explained, and Illustrated*, an 1871 work that addresses Shakespeare's general knowledge of ornithology and natural history. *Shakespeare's London*, by H.T. Stephenson (New York: Henry Holt and Co., 1905), primarily an outline of the city "as it was seen by Shakespeare," describes the customs, theaters, taverns, main highways, the Tower of London, and the waterfront.

Collared Peccaries (p. 60)

For general, nontechnical information on collared peccaries, see the section on hogs, pigs, and peccaries in E.P. Walker's *Mammals of the World*, vol. 2, pp. 1357–66 (Baltimore: The Johns Hopkins University Press, 1975), and H. Frädrich's article on swines and peccaries in *Grzimek's Animal Life Encyclopedia*, vol. 13, pp. 76–108. *The Journal of Wildlife Management* has published a number of articles on collared peccaries; among the most notable are T.A. Eddy's "Foods and Feeding Patterns of the Collared Peccary in Southern Arizona" (vol. 25, pp. 248–57); J.E. Ellisor and W.F. Harwell's "Mobility and Home Range of Collared Peccary in Southern Texas" (vol. 33, pp. 425–27); and R.E. Schweinsburg's "Home Range, Movements, and Herd Integrity of the Collared Peccary" (vol. 35, pp. 455–60). S.W. Herring's "The Role of Canine Morphology in the Evolutionary Divergence of Pigs and Peccaries" (*Journal of Mammalogy*, vol. 53, pp. 500–512) suggests that primitive pigs and peccaries developed different population structures and that the initial canine modification in pigs was a response to social selection pressure. H. Frädrich examines social behavior in pigs and compares it with that of peccaries in "A Comparison of Behaviour in the *Suidae*," an article in a two-volume publication, *The Behaviour of Ungulates and its Relation to Management*, edited by V. Geist and F. Walther (Morges: IUCN, 1974). This work also includes L.K. Sowl's "Social Behaviour of the Collared Peccary, *Dicotyles tajacu (L.)*." Another piece by Sowls is "Reproduction in the Collared Peccary," a chapter in *Comparative Biology of Reproduction in Mammals*, edited by R.W. Rowlands (London: Zoological Society of London, 1966). While researching techniques of trapping, tagging, and transplanting the collared peccary, B.J. Neal obtained "miscellaneous information" on the animal's life history, such as its breeding habits, protective behavior, and parental relations, and established that peccaries are faithful to home ranges. These observations are presented in "A Contribution on the Life History of the Collared Peccary in Arizona" (*American Midland Naturalist*, vol. 61, pp. 177–90). J.A. Bissonette investigates how varying temperatures affect collared peccaries' feeding and bedding behavior in "The Influence of Extremes of Temperature on Activity Patterns of Peccaries" (*The Southwestern Naturalist*, vol. 23, pp. 339–46). R.M. Wetzel introduced the chacoan peccary, which he found in a Paraguay thorn forest, in "The Chacoan Peccary, *Catagonus wagneri (Fusconi)*" (*Bulletin of the Carnegie Museum of Natural History*, vol. 3, pp. 1–36).

Rita Campon

Faces from the Past

Most of the attics in the American Museum of Natural History are tucked beneath the long rooftops and Romanesque towers of the Museum's main building. The attics house an odd assortment of things, from elephant bones to Margaret Mead's old Edison phonograph.

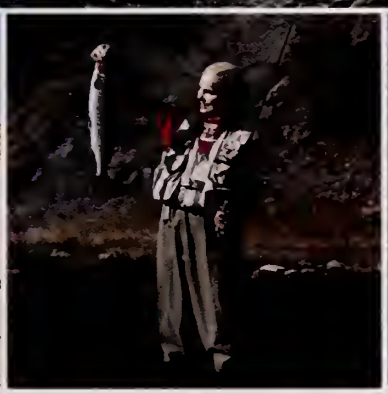
One tower attic, the highest point in the Museum, is reached by climbing a narrow stairway from the sixth-floor storage areas. Echoing down the stairwell is the sound of a mountain stream, created by water circulating in a sprinkler tank. At the top of the stairs is the tank itself, guarded by a wooden statue of a woman carved by Northwest Coast Indians a century ago.

An attic room to the right, illuminated by ancient skylights, contains the Museum's large collection of life casts. Shelf after shelf is lined with plaster busts of once-living Indians, Africans, Siberians, Eskimos, and a few Patagonians. They look out over the garret with blank eyes, the only part of a face that cannot be cast. Some of the life casts are identified by name—Mrs. Lost Horse, Thomas Pretty Back, Ghost Face, and Maggie Old Eagle, all Oglala Sioux; Bonifacio, a Patagonian; Ujaragapssug, a Smith Sound Eskimo; Lumbango, a Congo Bahumba; Annie McKay, a Tlingit Indian; Shenandoah, an Oneida; and Joe Colorado, a Cocapa. Other faces are identified only by tribe or culture.

In a far corner of the attic is a pile of cast arms and legs, looking like a broken heap of dolls. These were cast from life in various positions—flexed, extended, relaxed, gripping imaginary objects, and so on.

The life casts were collected in the field about the turn of the century by various Museum curators and scientists, including Franz Boas, Adm. Robert E. Peary, Waldemar Borgoras, and Casper Mayer. Physical anthropology—in particular the study of racial types—had a large following at that time, and expeditions customarily brought back (in addition to the usual baskets, pots, and other aspects of material culture) hundreds of anthropometric measurements, casts, skeletons, and photographs that look like mug shots with front, side, and rear views. It was also common practice to record vast mythological cycles, innumerable afterworld beliefs, legends, and tales in the original languages. The Museum's scientists shared the belief that most aboriginal cultures were doomed and that whatever could be preserved for future study and the common heri-

Sculptor Sigurd Neandross, in his studio in 1908, cradles one of his life casts. AMNH



Very easy to take.

HOPEWELL ROCKS, NEW BRUNSWICK

CAVENDISH, PRINCE EDWARD ISLAND

STEWIACKE RIVER, NOVA SCOTIA

WESTERN BROOK GORGE, NEWFOUNDLAND

Your family vacation in Canada's Atlantic provinces is very easy to take, for all kinds of very good reasons.

You are in easy driving distance of our provinces-by-the-sea. And when you cross our friendly border you'll find the roads a lot less crowded.

Or you can fly here. There are major airports in each of the four provinces with national car rentals available at each terminal. Or you can take the ferry. Drive aboard at Portland or Bar Harbor, Maine.

You'll quickly discover why people keep coming back.

Clean, fresh air and miles of uncrowded beaches. The kind of scenery that keeps cameras clicking, majestic highlands and rolling farmlands; silent fiords and tranquil fishing villages. And for a change of pace, sample city life as we live it. Remember, each of the four provinces also offers its own, unique attractions.

You can eat the freshest foods from land and sea. Spend your nights in a farmhouse, or snug in a home by the wave-washed shore. You can bring your tent or trailer, or take your pick from motels, hotels and fine resorts. You will also find your U.S. dollars are worth a whole lot more in Canada. Which means big savings on accommodation, meals, shopping and transportation.

You can swim, sail, golf, play tennis, fish; you can browse around, go to the theatre; or simply sit back and relax, knowing you are always welcome.

This vacation, come to Canada's Atlantic provinces. Very easy to take, but very hard to forget.

Life casts, replicated in the Museum's studios, were sold for $12 each.

tage of humanity should be saved at all costs. In short, they collected everything they could think of.

The life casts were shipped to the Museum, where sculptors fashioned busts with accurate hairstyles and ornamentation. During this period the Museum cast copies of the busts and sold them to other institutions for $12 each. The faces were collected for both modelmaking and study in physical anthropology and have been useful for Museum exhibit halls. In the Hall of Plains Indians, for example, the creased and melancholy faces of once-living men and women gaze imperturbably out of glass exhibit cases. Other real faces can be seen in the halls of Eastern Woodland Indians, Northwest Coast Indians, Eskimos, and most recently, in the new Hall of Asian Peoples.

The great Haida canoe at the 77th Street entrance to the Museum is propelled by life casts of Northwest Coast Indians. The Norwegian-American sculptor Sigurd Neandross, who was commissioned to create the figures in 1908, had to develop methods to cast larger body parts such as torsos. Since the weight of plaster distorts soft parts of the body, Neandross began by covering a subject's entire body with paraffin to create a stiff base for the plaster, working up from the feet to the head. Before applying the paraffin he placed threads strategically on the body so that when the plaster had barely set they could be drawn to cut the mold into parts. From the resultant pieces, Neandross cast torsos, arms, and legs to be assembled into figures. He may have cast some of the faces from molds that Franz Boas had made in British Columbia about the turn of the century. Casts of Northwest Coast clothing, masks, and ceremonial objects completed the figures.

The practice of making life casts—often by attaching real but unauthentic bodies to authentic faces—has continued to the present day. The Hall of Asian Peoples has the faces of several nineteenth-century Siberian Yakut; one is attached to the body cast of a young curatorial assistant in the Anthropology Department. Other figures were made from the head and hands of a Buddhist monk, and assorted arms, hands, and feet of willing Museum staff members.

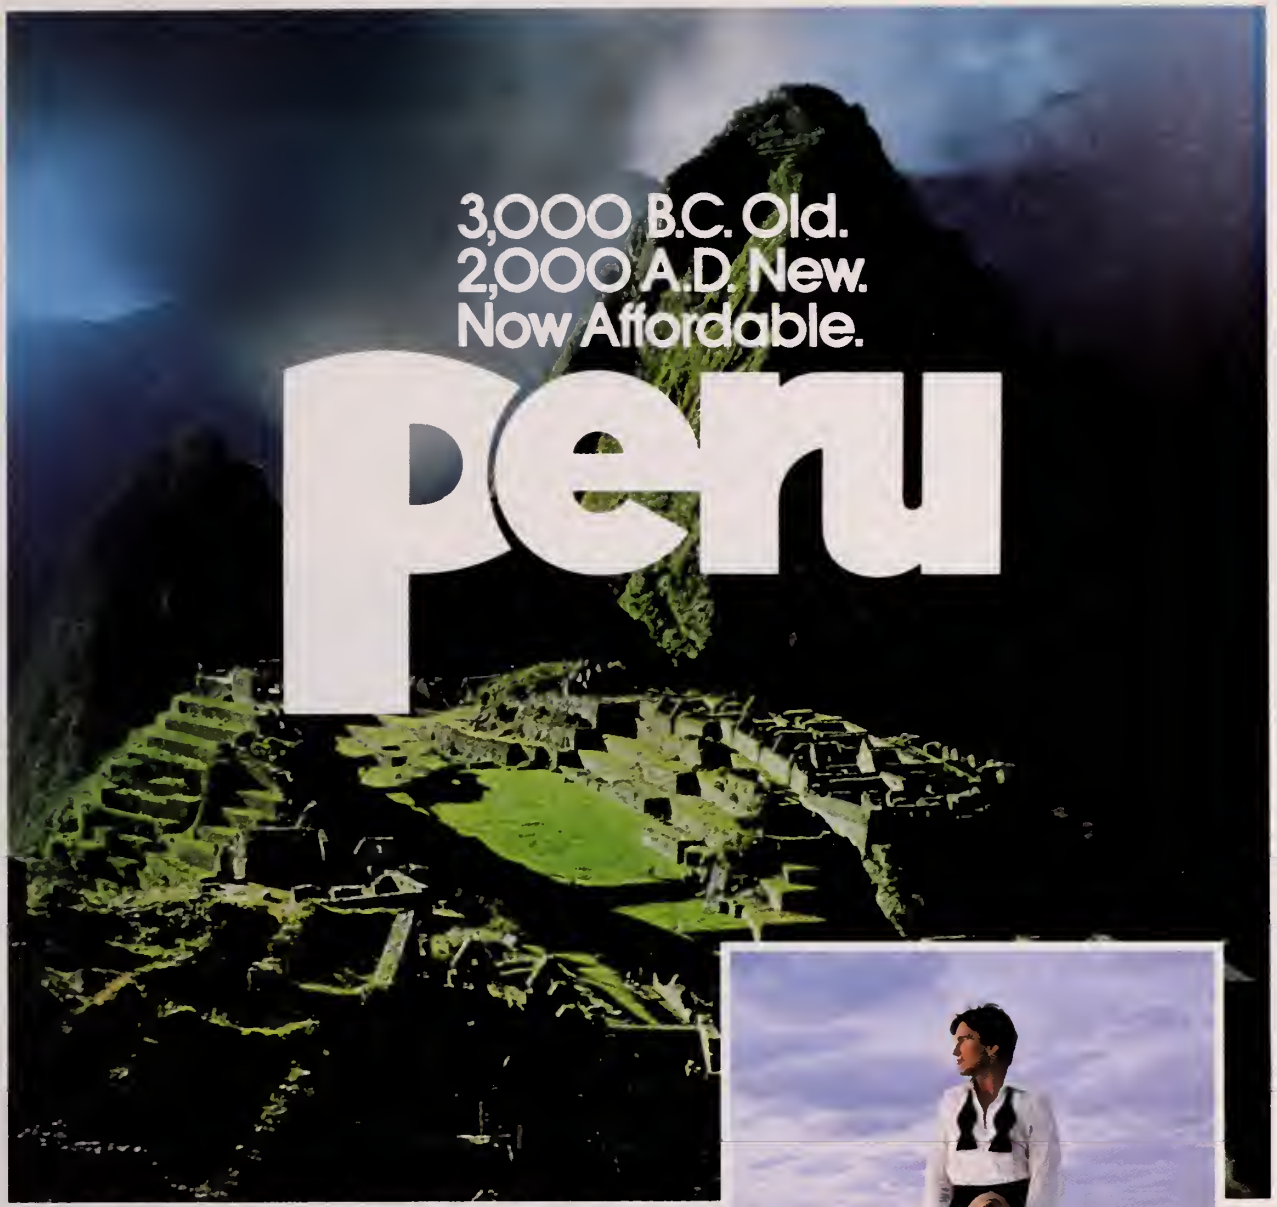
When the South American Hall is built, a few molds now in storage are sure to be cleaned and repoured, and a few more faces will emerge from the tower attic.

Douglas J. Preston

Japanese Textiles

An exhibit of Japanese textiles will open in Gallery 77 on June 25. *Japanese Textile Design* focuses on the designs of the Meiji period (the latter half of the nineteenth century) and includes some of the elaborate stencil patterns used to create the textiles. The appreciation of textile art spanned all levels of Japanese society, and the designs ranged from the creations of established workshops, patronized by wealthy aristocrats, to folk art forms that developed in rural Japan. Among the textiles on display will be *futons* (bed covers), *yutans* (chest covers), and *furoshikis* (textiles used for carrying objects). The exhibit emphasizes the Japanese love of nature and includes compositions displaying such natural objects as bamboo thickets, pine trees, chrysanthemums, peacocks, and butterflies. Many designs reflect Taoist and Zen Buddhist traditions.

A Man For All Time



A major exhibition, *Shakespeare: The Globe & the World*, opens at the American Museum of Natural History on Thursday, June 18. The exhibition looks at the Elizabethan era and includes four copies of the first folio of Shakespeare's works, other rare books and manuscripts, prints, paintings, engravings, and sculptures—all from the Folger Shakespeare Library in Washington, D.C. It is the first time the Folger Library has allowed its collection of Shakespeariana—the finest in the world—to leave its halls. Some rare items on display are William Caxton's 1498 edition of Chaucer's *Canterbury Tales*, the personal Bible of Elizabeth I, the 1594 quarto of *Titus Andronicus*—the only surviving copy of Shakespeare's first published play—and an illuminated prayer book presented to Henry VIII by his fourth wife, Anne of Cleves. *Shakespeare: The Globe & the World* also presents film and video clips of some modern presentations of Shakespeare's plays, including Zeffirelli's *Romeo and Juliet* and Kurosawa's *Throne of Blood* (*Macbeth*).

According to Thomas D. Nicholson, director of the Museum, "The exhibition presents a humanist world view that shaped Shakespeare's era, a time that included the birth of modern science and the age of exploration, areas of special interest to the Museum."

Shakespeare: The Globe & the World will coincide with *Shakespeare Summerfest*, a celebration of the Elizabethan age in performances, films, lectures, and concerts in the Museum and throughout the New York City area. The exhibition is made possible by grants from the National Endowment for the Humanities, Metropolitan Life Insurance Company, Exxon Corporation, and the Corporation for Public Broadcasting. It will close September 20.

June Events

Because of planned renovations to the Museum's Auditorium, the schedule for June events at the Museum is not ready at press time. To find out about June events, write to the Department of Education, American Museum of Natural History, Central Park West at 79th Street, New York, N.Y. 10024 and request a copy of the program brochure. Information about programs can also be obtained by calling (212) 873-7507.

The world is still wondering how a people who had not yet conceived of the wheel, managed to plan and build Machu Picchu, a city so advanced in architecture and road system.

It is not within the power of words to convey the visual excitement of Peru. This is a country so varied that it makes you wonder how man ever learned to dominate it. With the ocean, the Andes and the Amazon competing for attention, the eye is forever engaged. No other combination of elements could exert such an hypnotic effect on the visitor.

In dramatic contrast with its incomparable antiquities is Peru's modern capital, stunning Lima. However traveled, the tourist will not have found more impressive hotels on either side of the ocean, nor enjoyed more interesting food so graciously served.

It is often said that Lima is like a huge museum, with such religious and historical relics as the Cathedral on the Plaza de Armas where the remains of the conquistador, Pizarro, are displayed in a glass coffin. Nearby is the church of San Francisco, with catacombs rivaling those of Rome and priceless art treasures by well known masters.

Today, Peru is still beyond your imagination, but is no longer beyond your budget. See your travel agent or send for full-color literature that tells you everything you ought to see and ought to know about Peru.

The Lime That Failed

The tasty Key lime has been replaced by a fruit more suitable to the needs of mass-scale agriculture

by Raymond Sokolov

Some people go to Key West for the fishing. Others are attracted by the sunsets in this southernmost American town. Preservationists like to stroll among the island's old homes, visiting the Hemingway mansion or admiring the double elephant folios in the handsomely renovated place where Audubon sojourned while spying on the birds of the Keys and the Dry Tortugas. Many picturesque bars beckon those in search of a bibulous vacation, and in Key West's generally permissive atmosphere, gay people have established a discreet niche. Myself, I drove down from Miami, 160 miles on a highway that arches over the water from key to key, impelled by a lifelong desire to taste an authentic Key lime pie.

As I crossed the last bridge, from Stock Island onto Key West, I assumed I was only minutes from enjoying a rich slice of Florida's most famous regional specialty. But after a week of stuffing down piece after piece of one so-called Key lime pie after another, intermitted by various limeades and lime daiquiris supposedly based on the juice of the small, thin-skinned, legendarily sour and aromatic fruit known as *Citrus aurantifolia,* I came to realize that probably none of these pies or potions contained a single drop of freshly squeezed Key lime juice.

Indeed, after some serious inquiry among local experts, I am now morally certain that virtually all "Key lime" pies and drinks not prepared in private homes in the Keys are actually made with the juice of the Tahiti (or Persian or Bearss) lime, which is not a true lime at all. This hybrid of mysterious origin is the "lime" sold in supermarkets all over the country. Grown primarily in southern Florida and eastern Mexico, it is a satisfactory fruit, but it is not at all the equal of its cousin, *C. aurantifolia* (a.k.a. Key lime, Mexican lime, or West Indian lime).

Roughly twice as large as the Key lime, the Tahiti has a thick skin and looks enough like a small lemon, right down to its pointy end, that it is marketed while its rind is still an immature green. At maturity, Tahitis (and Key limes) turn yellow, and it would be easy for a consumer to confuse Tahitis and lemons. No one, however, would make this mistake with mature yellow Key limes, which are almost perfectly spherical. Sliced open, both varieties of lime are yellow green inside, but Tahitis are seedless, while most Keys have several seeds. Thin-skinned Keys can be easily juiced by pressing them between the thumb and forefinger. And, most important of all, the juice of the Key lime tastes decisively different from the juice of the Tahiti. It is sourer and more complex. In other words, Key lime juice has more personality.

I tested this in a comparative tasting. I also have finally managed to taste a real Key lime pie. And I must insist that, contrary to the opinion of innumerable cookbook authors who claim that "regular" lime juice is a completely adequate substitute, the real thing is far tangier and more interesting than "Key lime" pies that are made with Tahiti juice. The peel, often grated into pie fillings, may also play a role, as Key limes contain a distinctive essential oil in their peels, which is extracted industrially for cosmetics and for commercial flavoring. You can smell the delicious aroma easily if you hold the fruit to your nose.

It does not take a particularly educated nose or palate to appreciate the superiority and the greater sophistication of the Key lime. The problem is to find a Key lime.

In Key West, I made the rounds of local markets and fancy fruiterers in vain. Restaurants and drink stands used either Tahitis or a bottled juice sold in souvenir stands. This dull beverage, suspiciously labeled "real lime" juice, may, of course, be a chemically stabilized juice of real Key limes, but I doubt it. In any case, it is obviously not fresh juice, and anyone who has ever tasted freshly squeezed orange juice against juice that has been frozen or canned or merely stored in the refrigerator will know that the flavor of citrus juice degrades rapidly.

Far and away the strongest argument against the likelihood of any commercial American Key lime product being made from Key limes is that there is no regular commercial source of Key limes in the Florida Keys or anywhere else in the country. According to reliable authority, the last remaining sizable grove of trees is located at Islamorada, about midway between Miami and Key West, in the backyard of a restaurateur who freezes the juice he produces and uses it entirely for his own restaurant.

The persistent gastroethnographer can, nevertheless, lay his hands on fresh Key limes in the Florida Keys. But it helps if you know a Conch. Conchs are indigenous residents of the Keys (nicknamed after a shellfish abundant in local waters). Some Conchs have thorny little Key lime trees in their backyards. I located a luxuriant fruit-bearing tree on the

Photographs by Adelaide de Menil

Manny and Issa pick limes from their own trees

grounds of my motel in Key West and two others in a private botanical garden. Manny and Issa's Restaurant in Islamorada generously provided me with a bag of fruit. It would evidently not be difficult to find other small-scale private sources. But all these trees are mere remnants of what was once a thriving agricultural industry in the Keys and in the southern tip of the Florida mainland, where tropical weather and the good drainage of rocky soil are favorable to this idiosyncratic plant.

No one knows when the first Key lime was planted in the Keys. Citrus historians agree that the tree originated in Malaysia or eastern India. It was first mentioned in Europe in the thirteenth century, in Italy. Whether Columbus brought seeds of *C. aurantifolia* with him to Haiti in 1493 is a matter of conjecture, but it seems probable, since limes were flourishing on that island in 1520. Limes then spread gradually across the West Indies, westward to Mexico and northward to the Florida Keys, where trees were well established by 1839.

Primarily a home fruit throughout the remainder of the nineteenth century, the lime became a commercial crop in the Keys after 1906, when the combination of a severe hurricane and soil depletion forced Conchs to abandon pineapple culture. The Key lime was an ideal replacement since it thrives when meagerly fed. Lime production in the Keys peaked about 1923. Shortly afterward, the hurricane of 1926 dealt the Florida lime groves a death blow. The groves were never restored. It was much easier to exploit the same land as residential real estate for northern vacationers and retirees

or to replant it with more practical crops. One of these was the anomalous Tahiti lime. It probably arose from a chance cross in California, which imported large quantities of citrus fruit from Tahiti between 1850 to 1880. In any case, Tahiti limes were growing in Florida at least by 1883. Today, they are, to all intents and purposes, the only lime grown in the United States. Tahitis are also produced in Mexico, but primarily for export. Mexicans prefer true (Key) limes and pay a premium price for them, nearly twice what they will pay for Tahiti limes. No doubt smiling scornfully, Mexicans send us 16,620 metric tons of Tahitis in a year, but only about 62 tons of real limes, which are shipped into California and Arizona.

Americans, typically, have settled for a hybrid fruit of demonstrably inferior quality, but with ideal qualifications for modern agribusiness. The Tahiti lime is bigger and lends itself to mass-scale agriculture far more easily than the Key lime because it keeps better, has no thorns, and grows a thick skin perfect for machine handling and long truck trips. Of course, life in these United States goes on well enough without the Key lime. The traditional Key lime pie—a graham cracker shell filled with a sour custard made from juice, egg yolks, and sweetened condensed milk—tastes almost as good made with Tahiti lime juice. On the other hand, it is undeniably a fake.

Because of agronomic and financial reasons having nothing to do with food quality, we are all duped in a small way every time we buy a lime and get a convenient substitute. We are defrauded whenever we order a Key lime pie and are served a surrogate. And we are the victims of a horticultural shell game if we believe the Key lime is a rare and exotic form of lime. The poorest Caribbean waif can find real limes in his local marketplace, but in America we can only buy Tahiti limes in our glistening supermarkets. Even, or perhaps especially, in the Keys, the conspiracy to hide this botanical masquerade has succeeded almost completely in perpetuating the myth of a regional dish that actually disappeared, as far as the general public is concerned, almost as soon as it had been invented.

Raymond Sokolov, a writer with an interest in the history and preparation of food, is editor of Book Digest.

Gene Barnes's Key Lime Pie

(Adapted from *The Loaves and Fishes Cookbook,* by Susan Costner and Devon S. Fredricks, Wallflower Press, Box 1275, Bridgehampton, NY 11932)

- 6 egg yolks, beaten
- 1 15-ounce can sweetened condensed milk
- 2 tablespoons evaporated milk
- ½ cup freshly squeezed Key lime juice
- 1 tablespoon grated lime peel
- 1 recipe graham cracker crust (see below)
- ½ pint heavy cream, whipped

1. Beat together the egg yolks, the condensed milk, and the evaporated milk until smooth.
2. Stir in the lime juice and lime peel.
3. Line a 9-inch pie tin with the graham cracker crust.
4. Fill the crust with egg-milk-lime mixture.
5. Freeze.
6. When the filling has solidified, spread the top with whipped cream.

Yield: 8 servings

Graham Cracker Crust

- 1¾ cups graham cracker crumbs
- ½ cup sugar
- ⅓ cup butter, melted

Work all the ingredients together. This crust is meant to be pressed into the pie tin by hand, not rolled.

Old Sour

(From *Conch Cooking,* Florida Keys Printing & Publishing, 405 Fleming St., Key West, Fla. 33040)

- 2 cups Key lime juice
- 1 tablespoon salt

1. Use ripe yellow limes only. Mix the salt and lime juice and let stand for a while. Strain through two layers of cheesecloth as often as necessary to let the juice run through freely.
2. Put the juice into bottles and let stand several weeks before using. Some say old sour should be put into bottles of brown or green glass; others say it makes no difference.

Raw Conch Salad

Skin the conchs and mince very fine. Chop onions very fine. Add salt, pepper, and old sour or fresh lime juice. Let stand at least an hour to blend. Serve without lettuce. (Note: The recipe lacks quantities, but the resourceful cook will add enough onion to invigorate the salad without overwhelming it.) Salt and pepper should also be added "to taste." Use enough old sour or lime juice to moisten the conch bits and "cook" them, as in seviche.

"WHICH VOLKSWAGEN IS THIS?"

Whoever it was that said no product can be all things to all people obviously never drove a Jetta.

Because it's all our Volkswagens in one.

Hard to believe?

"ALL OF THEM."

It was even harder to achieve.

First, we made the Jetta handle like a Scirocco. By giving it rack-and-pinion steering, front-wheel drive, 4-wheel independent suspension and a powerful CIS fuel-injected engine.

Then, we made it luxurious like a Dasher.

With room enough to give a family of four the luxury of stretching their legs.

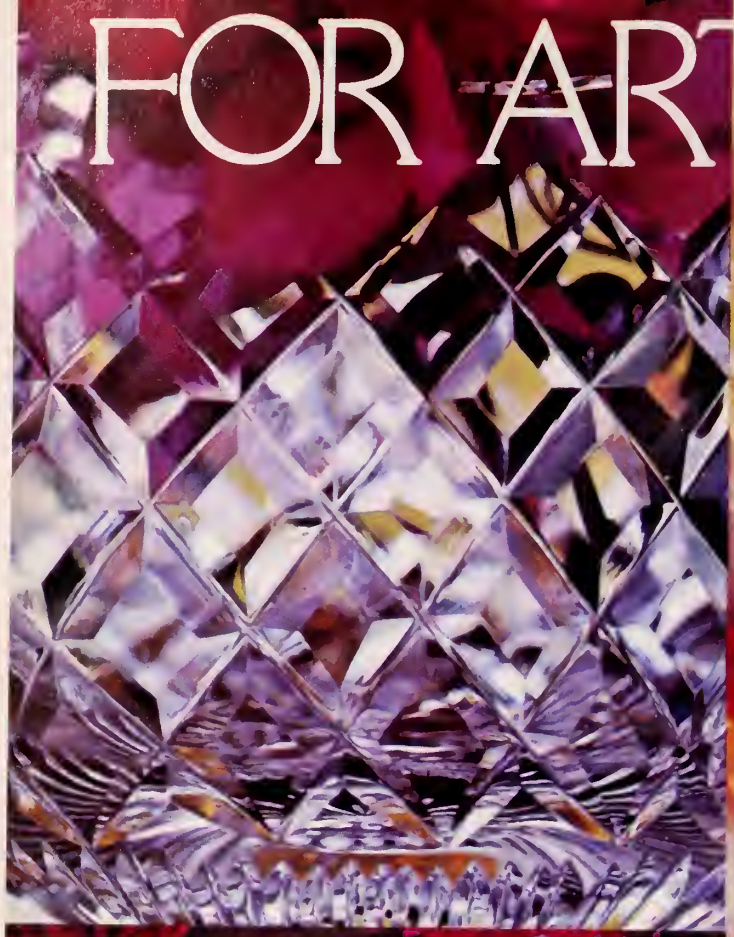
We even made the Jetta economical like a Rabbit.

How economical?

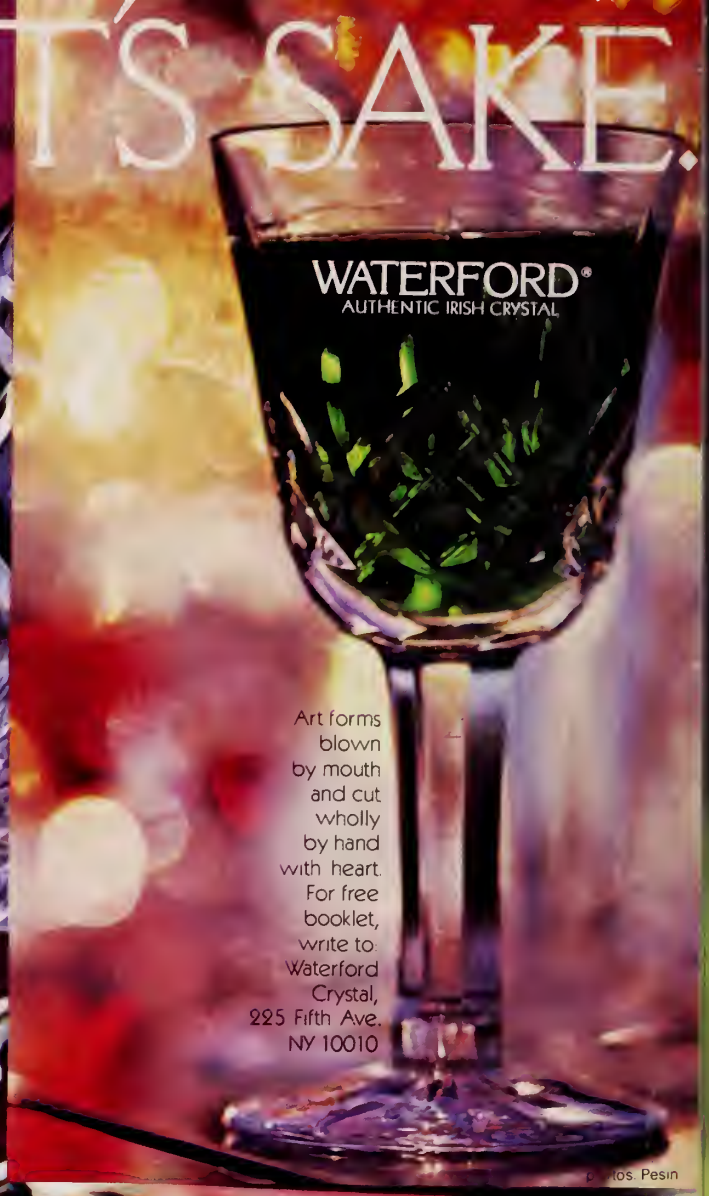
How about an EPA estimated 25 mpg, 40 mpg highway estimate? (Use "estimated mpg" for comparisons. Your mileage may vary with weather, speed and trip length. Actual highway mileage will probably be less.)

And, finally, we made sure the Jetta was meticulously designed, like a Jetta.

With attention-getting European styling, careful attention to even the smallest detail and a trunk large enough to handle 8 suitcases.



So now, thanks to Jetta, when a salesman asks if you want a performance car, a luxury car or an economy car, you can be decisive and say:



"All of them."

ANNOUNCING BY CADILLAC *Cimarron*

Quick-handling. Road-hugging. And fun to drive. This . . . is Cimarron. An efficient new kind of Cadillac. With the traction of front-wheel drive . . . MacPherson strut front suspension . . . and power-assisted rack and pinion steering with responsive 14:1 steering gear ratio. Plus, it has Cadillac refinements such as genuine leather seating areas, body-contoured bucket seats, air conditioning and more. All standard. Test-drive Cimarron by Cadillac. Due to limited initial production, Cimarron is not available at all Cadillac dealers at this time.

42 HWY EST 26* EPA EST MPG

*Use estimated mpg for comparison. Your mileage may differ depending on speed, distance, weather. Actual highway mileage lower. Cadillacs are equipped with GM-built engines produced by various divisions. See your Cadillac dealer for details.

A NEW KIND OF CADILLAC FOR A NEW KIND OF CADILLAC OWNER.

Authors

The son of a sculptor who works primarily with animal figures and the grandson of a watchmaker whose hobby was natural history, **François Vuilleumier** came by his interest in animals naturally. As a boy growing up in Geneva, he was frustrated by the nocturnal nature of most mammals in the area and began studying birds. In 1964, inspired in part by a desire to see the Indian dancers of the Bolivian high plateau, Vuilleumier made his first field trip to the Andes. Since then he has returned many times to continue his research on species formation and the biogeography of Andean birds. Vuilleumier, who received his Ph.D. from Harvard University, is a curator in the Department of Ornithology at the American Museum.

In 1967 **Marjorie L. Reaka**, then studying at the Bermuda Biological Station, became interested in stomatopods, or mantis shrimps, when she noticed their startling aggressive behavior. Now an assistant professor in the Department of Zoology at the University of Maryland, she has done fieldwork on the competition for space and food among coral-dwelling stomatopods and studied their rates of evolution. She has also examined the impact of fish predation on a variety of stomatopod species. Reaka has plans to study the rate of biodegradation of coral reefs, with special emphasis on organisms that bore into live and dead coral substrates.

Selling at around $4, Taylor California Cellars varietal wines are an outstanding value. Because they're better than the leading varietals in their price range. But don't take our word for it.

Read what one of the world's leading wine experts, Steven Spurrier, has to say about our Chardonnay: "It's dry, fresh and clean-tasting, with more character than I ever expected to find in a wine at the price. I'm especially impressed by the fruit/acid balance. All in all, this wine is really quite an achievement."

Enjoy Taylor California Cellars Chardonnay, as well as our other exceptional varietals—Zinfandel, Cabernet Sauvignon, Chenin Blanc, Riesling and Sauvignon Blanc. Around $4.00.

© 1981 TAYLOR CALIFORNIA CELLARS
GONZALES, CALIFORNIA 93926

Varietal wines from Taylor® California Cellars™. Better wines. Judge for yourself.

We're #1 to the world.

For two good reasons.

More people fly on Pan Am from America to places overseas than on any other airline.

Because Pan Am provides more of what demanding travelers demand.

Comfort and convenience.

For example, take comfort. To the Pan Am passenger, that may mean the unabashed luxury of First Class. With its spacious cabin and Sleeperette seats. (A Pan Am first, we might add.)

Or comfort could be Clipper® Class. Our separate section especially for business travelers. In Clipper Class, no one sits in the middle. No matter where in the world one is flying.

Sleeperette service® and Clipper Class are available on most of our widebodies. And we've got more widebodies than any other airline.

But offering more widebodies is just the beginning of our convenience story. For another chapter, consider this:

Pan Am can take passengers from more of the U.S. to more of the world than any other airline. From 25 U.S. cities to 47 cities around the world.

All with one ticket. One baggage check-in. On one airline.

If all this isn't reason enough to get you to fly us, we've got more coming. More ways to make your trip even more comfortable. Even more convenient.

Because at Pan Am, we intend to keep on giving you reasons for making us your number one choice.

Say hello to Pan Am.

PAN AM

What, if Anything, Is a Zebra?

Are the three species a genealogical unit or a disparate group of horses with some confusing similarities?

by Stephen Jay Gould

Each year, professional scientists scan thousands of titles, read hundreds of abstracts, and study a few papers in depth. Since titles are the commonest, and usually the only, form of contact between writers and potential readers in the great glut of scientific literature, catchy items are appreciated and remembered, but unfortunately rare. Every scientist has his favorite title. Mine was coined by paleontologist Albert E. Wood in 1957: "What, if Anything, Is a Rabbit?" (*Evolution*, vol. 11, pp. 417–25).

Wood's question may have been wry, but his conclusion was ringing: rabbits and their relatives form a coherent, well-defined order of mammals, not particularly close to rodents in evolutionary descent. (And thank goodness for small favors as I write this column on a quiet Easter Sunday evening.) I was reminded of Wood's title last month when I read a serious challenge to the integrity of a personal favorite among mammals: the zebra. Now don't get too agitated. I am not trying to turn the world of received opinion upside down. Striped horses manifestly exist. But do they form a true evolutionary unit? With "Stripes Do Not a Zebra Make"—a quite respectable title in its own right—Debra K. Bennett has forced us to extend Wood's question to another group of mammals (*Systematic Zoology*, vol. 29, pp. 272–87). What, if anything, is a zebra?

Since evolutionary descent is our criterion for biological ordering, we define groups of animals by their genealogy. We do not join together two distantly related groups because their members have independently evolved some similar features. Humans and bottle-nosed dolphins, for example, share the pinnacle of brain size among mammals. But we do not, for this reason, establish the taxonomic group Psychozoa to house both species—for dolphins are more closely related by descent with whales and humans with apes. We follow the same principles in our own genealogies. A boy with Down's syndrome is still his parents' son and not, by reason of his affliction, more closely related to other Down's children, no matter how long the list of similar features.

The potential dilemma for zebras is simply stated: they exist as three species, all with black-and-white stripes to be sure, but differing notably in both numbers of stripes and their patterns. (A fourth species, the quagga, became extinct early in this century; it formed stripes only on its neck and forequarters.) These three species are all members of the genus *Equus*, as are true horses, asses, and donkeys. (In this essay, I use "horse" in the generic sense to specify all members of *Equus*, including asses and zebras. When I mean Old Dobbin or Man o'War, I will write "true horses.") The integrity of zebras then hinges on the answer to a single question: Do these three species form a single evolutionary unit? Do they share a common ancestor that gave rise to them alone and to no other species of horse? Or are some zebras more closely related by descent to true horses or to asses than they are to other zebras? If this second possibility is an actuality, as Bennett suggests, then horses with black-and-white stripes arose more than once within the genus *Equus*, and there is, in an important evolutionary sense, no such thing as a zebra.

But how can we tell, since no one witnessed the origin of zebra species (or at least australopithecines weren't taking notes at the time), and the fossil record is, in this case, too inadequate to identify events at so fine a scale. During the past twenty years, a set of procedures has been codified within the science of systematics for resolving issues of this kind. The method, called cladistics, is a formalization of procedures that good taxonomists followed intuitively but did not properly express in words, leading to endless quibbling and fuzziness of concepts. A clade is a branch on an evolutionary tree, and cladistics attempts to establish the temporal order of branching for a set of related species.

Cladistics has generated a fearful jargon, and many of its leading exponents in America are among the most contentious scientists I have ever encountered. But behind the names and nastiness lies an important set of principles. Still the clear formulation of principles does not guarantee an unambiguous application in each case—as we shall see for our zebras.

I believe that we can get by with just two terms from the bounty offered by cladists. Two lineages sharing a common ancestor from which no other lineage has sprung form a *sister group*. My brother and I form a sister group (pardon the confusion of gender) because he is my only sib and neither of my parents had any other children.

Cladists attempt to construct hierarchies of sister groups in order to specify temporal order of branching in evolutionary history. For example: gorillas and chimpanzees form a sister group because no other primate species branched from their common ancestor. We may then take the chimp-gorilla sister group as a unit and ask which primate forms a sister group with it. The answer, according to most experts, is us. We now have a sister group with three species, each more closely related to its two partners than to any other species.

We may extend this process indefinitely to form a chart of branching relationships called a cladogram. But

AS LUXURY SEDANS BECOME MORE EXPENSIVE, THEIR INHERENT WORTH BECOMES MORE CRITICAL.

Due to a variety of economic ills, the day has finally arrived when the price of a luxury automobile can rival that of a small house in the country.

A disturbing trend that has forced many otherwise casual automobile buyers to scrutinize their potential purchases as never before.

At BMW we are not alarmed by this newly enlightened consumer.

For when one examines the features that truly matter in a luxury sedan—performance, craftsmanship and resale value—no other expensive automobile justifies its price quite so thoroughly as the BMW 733i.

Accounting, no doubt, for the fact that last year the demand for the BMW 733i outpaced even our most optimistic predictions.

EVOLUTION IS PREFERABLE TO REVOLUTION.

With a certain predictability, automakers reacted to the realities of the 1980's by bringing forth a plethora of "revolutionary" re-engineered cars.

The 733i, however, is hardly the result of a single year's rush to build an enlightened automobile.

Indeed, decades ago, when luxury car manufacturers were building ever larger cars, reckless in their consumption of fuel, BMW was championing such avant-garde concepts as six-cylinder engines, sensible piston displacements and impressive power-to-weight ratios.

The BMW 733i's 3.2-liter, fuel-injected power plant, for example, is the product of millions of miles of testing and refinement—on and off the great racecourses of the world.

Its double-pivot suspension system has been described by Car and Driver magazine as "...the single most significant breakthrough in front suspension design in this decade."

A five-speed standard transmission (automatic is available) affords one the unique opportunity to pick and choose one's own gears.

ELECTRONIC INNOVATION THAT GOES BEYOND A DIGITAL SPEEDOMETER.

On the BMW 733i, our electronic computerized monitoring system (first installed by BMW in 1975) plays a far more important role than mere decoration: it actually improves the car's efficiency.

With every engine revolution a computer receives and assesses signals from sensors deep within the 6-cylinder engine. Then instantly determines the precise air/fuel mixture to be injected into the cylinder ports.

Yet the incongruous note here is that BMW efficiency is not achieved at the expense of the sort of exhilarating performance one expects in a BMW—or the power reserves necessary to maneuver safely even under the most demanding conditions.*

LUXURY, NOT SUPERFICIALITY.

It would be difficult to imagine an appointment or an accessory that has been omitted in the BMW 733i.

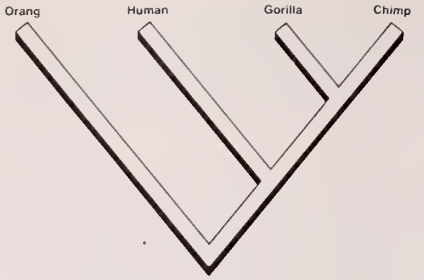
Yet, all facets have been biomechanically engineered to achieve the perfect integration of man and machine.

Its seats are anatomically correct buckets and covered in wide rolls of supple leather.

All of its vital controls are within easy reach of the driver. Instruments are large, well-marked and totally visible.

So impressive is the total result that one automotive journalist was moved to write of the BMW 733i, "...to drive it is to know all the wonderful things machines can do for man."

To arrange a thorough test drive, we suggest you phone your nearest BMW dealer at your convenience.



THE ULTIMATE DRIVING MACHINE.

*The 733 (with standard transmission) delivers 16 EPA estimated mpg, 25 estimated highway mileage and, based on these figures, an estimated mpg range of 360 miles and a highway range of 562 miles. (Naturally, our fuel efficiency figures are for comparison purposes only. Your actual mileage and range may vary, depending on speed, weather and trip length. Your actual highway mileage and highway range will most likely be lower.) © 1981 BMW of North America, Inc. The BMW trademark and logo are registered trademarks of Bayerische Motoren Werke A.G.

consider just one more step: What primate species is the sister group to the human-chimp-gorilla unit? Conventional wisdom cites the orangutan, and we add it to our cladogram.

This cladogram of "higher" primates contains an interesting implication: there is no such thing as an ape, at least as usually defined. There may be several species of primates that swing through trees, eat bananas in zoos, and form good prototypes for science fiction of various sorts. But orangs, chimps, and gorillas (the "apes" of our vernacular) are not a genealogical unit because orangs are cladistically more distant from chimps and gorillas than humans are—and we originally defined the term ape to contrast some lesser forms with our exalted state, not to include us!

The zebra problem can also be placed in this context. If the three species of zebras form a sister group (as humans, chimps, and gorillas do on our cladogram), then each is more closely related to its two partners than to any species of horse, and zebras form a true evolutionary unit. But if zebras are like "apes," and another species of horse lies within the cladogram of zebras (as humans lie within the cladogram of traditional apes), then striped horses may share some striking similarities meriting a common vernacular term (like zebra), but they are not a genealogical unit.

Joe Le Monnier

But how do we identify sister groups correctly? Cladists argue that we must search for—and here comes the second term—*shared derived characters* (technically called synapomorphies). Primitive characters are features present in a distant common ancestor; they may be lost or modified independently in several subsequent lineages. We must be careful to avoid primitive characters in searching for common features to identify sister groups, for they spell nothing but trouble and error. Humans and many salamanders have five toes; horses have one. We may not therefore state that humans are more closely related to salamanders than to horses, and that the concept of "mammal" is therefore a fiction. Rather, five toes is an inadmissible primitive character. The common ancestor of all terrestrial vertebrates had five toes. Salamanders and humans have retained the original number. Horses—and whales and cows and snakes and a host of other vertebrates—have lost some or all of their toes.

Derived characters, on the other hand, are features present *only* in members of an immediate lineage. They are unique and newly evolved. All mammals, for example, have hair; no other vertebrate does. Hair is a derived character for the class Mammalia because it evolved but once in the common ancestor of mammals and therefore identifies a true branch on the family tree of vertebrates. Shared derived characters are held in common by two or more lineages and may be used to specify sister groups. If we wish to identify the sister group among tunas, seals, and bobcats, we may use

...And suddenly it was as though I was next to him. I could make out every detail with incredible clarity and brilliance; the moist eyes, each feather stood out in startling detail. It was a moment I would never forget. I was glad I chose Nikons."

It's moments like these that make you glad you didn't settle for anything less than Nikon Binoculars. Their superb optics and uncompromising prism-lock construction are designed to give years of flawless performance even under the toughest conditions.

There are more than 20 Nikon Binoculars to choose from. See them at your Nikon dealer or write Nikon Inc., Dept. 26, 623 Stewart Ave., Garden City, N.Y. 11530.

Nikon

hair as a shared derived character to unite the two mammals and to eliminate the fish.

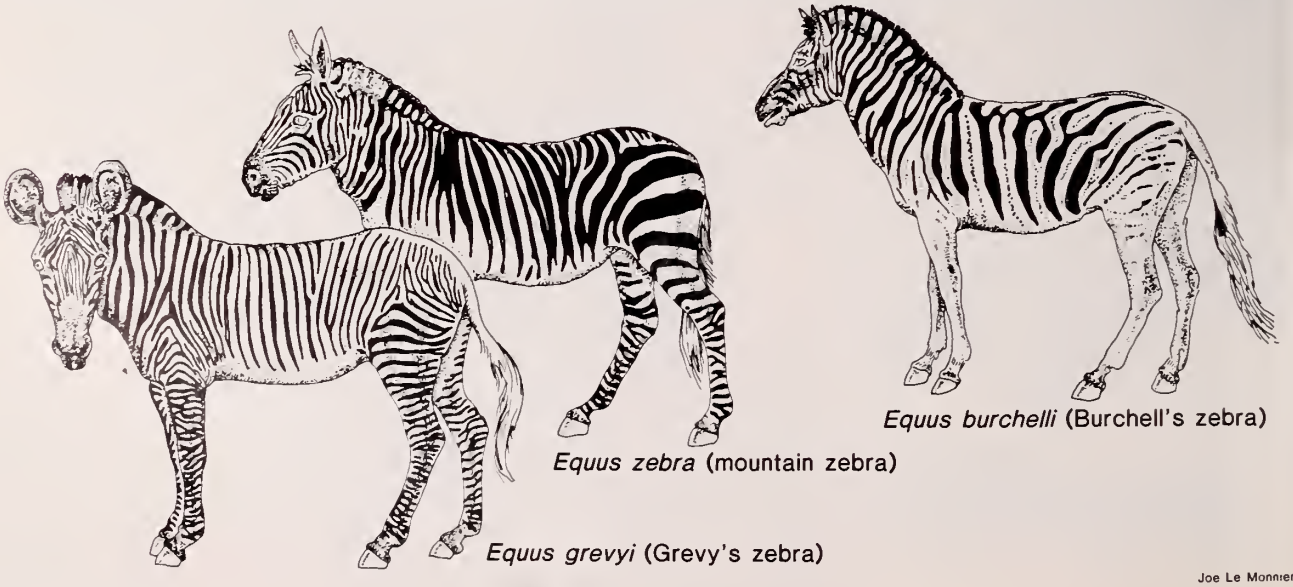
For zebras, the question then becomes: Are stripes a shared derived character of the three species? If so, the species form a sister group and zebras are a genealogical unit. If not, as Bennett argues, then zebras are a disparate group of horses with some confusing similarities.

The method of cladistics is both simple and sensible: establish sequences of sister groups by identifying shared derived characters. Unfortunately, conceptual elegance does not guarantee ease of application. The rub, in this case, lies in determining just what is or is not a shared derived character. We have some rough guidelines, and some seat-of-the-pants feelings, but no unerring formulas. If derived characters are sufficiently "complex," for example, we begin to feel confident that they could not have evolved independently in separate lineages and that their mutual presence therefore indicates common descent.

Chimps and gorillas share a set of complex and apparently independent modifications in several of their chromosomes (mostly "inversions," literally, the turning around of part of a chromosome by breaking, flipping, and reattaching). Since these chromosomal modifications are complex and do not seem to represent an "easy" modification so adaptively necessary that separate lineages might evolve them independently, we mark them as shared derived characters present in the common ancestor of chimps and gorillas, and in no other primate. Hence they identify chimps and gorillas as a sister group.

Unfortunately, most derived characters are more ambiguous. They tend to be easy to construct or so advantageous that several lineages might evolve them independently by natural selection. Many mammals, for example, develop a sagittal crest—a ridge of bone running along the top of the skull from front to back and serving as an attachment site for muscles. Most primates do not have a sagittal crest, in part because large brains make the cranium bulge and leave neither room nor material for such a structure. But a general rule for scaling of the brain in mammals holds that large animals have relatively smaller brains than relatives of diminished body size. Thus the largest primates have a sagittal crest because

their relatively small brains do not impede its formation. (This argument does not apply to the great oddball *Homo sapiens*, with an enormous brain despite its large body.) The largest australopithecine, *Australopithecus boisei*, has a pronounced sagittal crest, while smaller members of the same genus do not. And gorillas have a sagittal crest, while most smaller primates do not. We would make a great error if, using the sagittal crest as a shared derived character, we united an australopithecine with a gorilla in a sister group and linked other, smaller-bodied australopithecines with marmosets, gibbons, and rhesus monkeys. The sagittal crest is a "simple" character, probably part of the potential developmental repertoire for any primate. It comes and goes in evolution, and its mutual presence does not indicate common descent.



Bennett bases her cladistic analysis of the genus *Equus* on skeletal characters, primarily of the skull. All horses are pretty much alike under the skin, and Bennett has not found any shared derived characters as convincing as the chromosomal similarities of chimps and gorillas. Most of her characters are, by her own admission, more like the sagittal crest—hence the provisional nature of her conclusions.

Bennett argues that the genus *Equus* contains two major cladistic groups—donkeys and asses on one side and true horses and zebras on the other. Thus, zebras pass the first test for consideration as a genealogical unit. Unfortunately (or not, according to your point of view), Bennett claims that they fail the second test. She does identify the Burchell and Grevy zebras (*Equus burchelli* and *E. grevyi*) as a sister group. But in Bennett's scheme, the third species, the mountain, or Hartmann, zebra (*E. zebra*) does not join its cousins to form a larger sister group. Instead, the sister species of the mountain zebra is none other than Old Dobbin himself, the true horse (*E. caballus*)! Thus, mountain zebras join with true horses before they connect with other zebras. Old Dobbin is inextricably intercalated into the cladogram of zebras—and since he is not a zebra by any definition, then what, if anything, is a zebra?

But Bennett's analysis is based upon only three characters, none very secure. All are potentially simple modifications of shape or proportion, not presences or absences of complex structures. All, like the sagittal crest, could come and go. Only one potential shared derived character unites true horses with *E. zebra:* the "orientation of postorbital bars relative to horizontal plane" (a relatively less slanted position for a bar of bone located on the skull behind the eyes—not exactly the stuff of which confident conclusions are made). Only two potential shared derived characters unite Burchell and Grevy zebras: the presence of frontal doming (inflation of the top part of the skull) and relative skull breadth (these two zebras have long and narrow snouts). Unfortunately, we know that at least one of these characters doesn't work very well for Bennett's cladistic scheme because she admits that a member of her other lineage—a horse with the peculiar moniker of the Asiatic half-ass (*E. hemionus*)—has independently evolved a long, narrow snout. If twice, why not three times?

When we look for corroboration to an obvious source—numbers of chromosomes—we are again disappointed. As I discussed in my column of November 1980, the various species of horses, despite their marked similarities of form, differ greatly in numbers of chromosomes. Fusion or fission of chromosomes may be a major mechanism of speciation in mammals, and these differences may therefore have great evolutionary significance. True horses have 64 chromosomes, and one of the zebras shares this number exactly. Unfortunately, it is not *E. zebra*, as Bennett's cladistic scheme would suggest. It is the Grevy zebra, *E. grevyi*. Only two horses have fewer than 50 chromosomes—the mountain zebra with the minimum of 32 and the Burchell zebra with 44—but these species do not form a sister group in Bennett's arrangement. These facts do not necessarily count against Bennett's conclusions, however. Sixty-four could be the original number for the genus *Equus*. In that case, it would be a shared *primitive* character in true horses and Grevy zebras, and would not specify a sister group. Similarly, the shared low chromosome number of mountain and Burchell zebras could represent two independent evolutionary sequences of reduction. Still, there is nothing in the chromosome data that should encourage Bennett.

I conclude that Bennett's proposal is interesting, but very much unproven. Suppose, however, that she is right. What then would a zebra be? Or more specifically, how did cla-

Equus burchelli (Burchell's zebra)

Equus zebra (mountain zebra)

Equus grevyi (Grevy's zebra)

Joe Le Monnier

Is this country in the autumn of its time?

There are those who say this country is in the autumn of its time. That we have lost our pride, and quality no longer is a way of life.

Whirlpool disagrees.

As a maker of home appliances, we believe that pride and quality are so much a part of this country's heritage we must be true to them in everything we make.

Whirlpool believes that this is not the onset of winter but the advent of spring.

A new beginning, where quality will once again become a way of life for everyone.

Whirlpool

distically unrelated horses get black-and-white stripes? There are two possibilities. Either the common ancestor of zebras and true horses had stripes and true horses lost them, while the three species of "zebras" passively retained them; or else, striping is an inherited developmental capacity of all horses and not so complex a character as it appears. In this case, several separate lineages could acquire stripes independently. This second possibility not only has some evidence going for it, but also raises several interesting issues in evolutionary theory. (I shall have to defer this subject to next month's column. Unlike other unfulfilled promises to discuss a tantalizing subject "next month," I will come through this time, for the piece is already written.) Zebras would then be horses that have realized a potential pathway of development probably common to many or all members of the genus *Equus*.

This cladistic tale of zebras may not hold, but the radical messages of cladistic ordering are secure in many cases. Some of our most common and comforting groups no longer exist if classifications must be based on cladograms. With apologies to Mr. Walton and to so many coastal compatriots in New England, I regret to report that there is surely no such thing as a fish. About 20,000 species of vertebrates have scales and fins and live in water, but they do not form a coherent cladistic group. Some—the lungfishes and the coelacanth in particular—are genealogically close to the creatures that crawled out on land to become amphibians, reptiles, birds, and mammals. In a cladistic ordering of a trout, a lungfish, and any bird or mammal, the lungfish must form a sister group with the sparrow or elephant, leaving the trout in its stream. The characters that form our vernacular concept of "fish" are all shared primitive and do not therefore specify cladistic groups.

At this point, many biologists rebel, and rightly I think. The cladogram of trout, lungfish, and elephant is undoubtedly true as an expression of branching order in time. But must classifications be based only on cladistic information? A coelacanth looks like a fish, tastes like a fish, acts like a fish, and therefore—in some legitimate sense beyond hidebound tradition—*is* a fish.

No debate in evolutionary biology has been more intense during the past decade than the challenge raised by cladistics against traditional schemes of classification. The problem arises from the complexity of the world, not the fuzziness of human thought (although woolliness has made its usual contribution as well). There are two components to our vernacular conception of "similarity" between organisms—and classifications are designed to reflect relative degrees of similarity. On the one hand, we have genealogy, or branching order. Cladistics works with branching order alone, rigorously excluding any other notion of similarity. But what about the admittedly vague and qualitative, but not therefore unimportant, notion of overall similarity in form, function, or biological role? The coelacanth, to say it again, looks and acts like a fish even if its closer cladistic relatives are mammals. Indeed, another theory of classification, called phenetics—from a Greek work for appearance—focuses on overall similarity alone and tries to escape from the charge of subjectivity by insisting that phenetic classifications be based upon large suites of characters, all expressed numerically and processed by computer.

Unfortunately, these two types of information—branching order and overall similarity—do not always yield congruent results. The cladist rejects overall similarity as a snare and delusion and works with branching order alone. The pheneticist attempts to work with overall similarity alone and tries to measure it in the vain pursuit of objectivity. The traditional systematist tries to balance both kinds of information but often falls into hopeless subjectivity because they really do conflict. Coelacanths are like mammals by branching order and like trout by biological role. Thus, the cladists buy potential objectivity at the price of ignoring biologically important information. And the traditionalists curry confusion and subjectivity by trying to balance two legitimate, but often disparate, sources of information. What is to be done?

I cannot answer this question, as it raises issues of style, mores, and methodology more than demonstrable substance. But I can at least comment on the source of this bitter debate—a rather simple point that somehow got lost in the heat. In an ideal world, there would be no conflict among the three schools—cladistics, phenetics, and traditional—and all would produce the same classification for a given set of organisms. In this pipedream world, we would find a perfect correlation between phenetic similarity and recency of common ancestry (branching order); that is, the longer ago two groups of organisms separated from a common ancestor, the more unlike they would have become in appearance and biological role. Cladists would establish an order of branching in time by cataloging shared derived characters. Pheneticists would crunch their numerous measures of similarity in their favorite computers and find the same order because their most dissimilar creatures would have the most ancient common ancestors. Traditionalists, finding complete congruence between their two sources of information, would join the chorused harmony of agreement.

But let the reverie halt. The world is much more interesting than ideal. Phenetic similarity often correlates very poorly with recency of common ancestry. Our ideal world requires a constancy of evolutionary rate in all lineages. But rates are enormously variable. Some lineages change not at all for tens of millions of years; others undergo marked alterations in a mere thousand. When the forebears of terrestrial vertebrates first split off from a common ancestry with coelacanths, they were still unambiguously fish in appearance. But they have evolved, along numerous lines during some 250 million years, into frogs, dinosaurs, flamingos, and rhinoceroses. Coelacanths, on the other hand, are still coelacanths. By branching order, the modern coelacanth may be closer to a rhino than a tuna. But while rhinos, on a rapidly evolving line, are now so different from that distant common ancestor, coelacanths still look and act like fish—and we might as well say so. Cladists will put them with rhinos, pheneticists with tunas; traditionalists will hone their rhetoric to defend a necessarily subjective decision.

Nature has imposed this conflict upon science by decreeing, through the workings of evolution, such unequal rates of change among lineages and such a poor correlation between phenetic similarity and recency of common ancestry. I do not believe that nature frustrates us by design, but I rejoice in her intransigence nonetheless.

A Pilgrimage in India

Where tourism is economically unthinkable, the pilgrimage may serve a similar function

by Colin Turnbull

While the concept of the tourist as a pilgrim who is searching for more than mere escape might be easy to accept, the notion that tourism and pilgrimage bear more than a superficial resemblance to each other is not. Yet observing American tourists in Europe and the Middle East, I perceive a conscious desire to identify with historical and spiritual roots. There is a moment of fleeting recognition when the tourist says, "Yes, this is who I am, this is where I came from, this is where I really belong." A sense of belonging, to a religious or spiritual heritage rather than a cultural one, is surely the reward of the true pilgrim. So perhaps we have to think in terms of alternative categories of quest, sacred or secular, rather than in terms of alternative institutions.

Still, so fixed is the equation of tourism with escape and holiday-making that we are reluctant to consider it in the same light as the pilgrimage. Yet if we are to understand tourism, we must at least examine the possibility that it is a latter-day form of pilgrimage. We tend to think of tourism as a contemporary phenomenon because only since the introduction of jet aircraft have distant parts of the world become accessible within the short time span of the annual vacation, and only recently has the combination of relative affluence and the credit-card system enabled any but the wealthy to afford extensive travel. But this is not so.

For centuries there has been considerable population movement (with many of the same political, economic, and domestic consequences as tourism) in the form of the pilgrimage. Further, the pilgrimage has generally been available to the poor, as well as the rich; to the unemployed, time is of no concern, and others have received some consideration because of the deserving nature of the enterprise, which frequently entailed hardship, danger, and some sacrifice. But as Chaucer has recounted, the pilgrimage was by no means all hardship nor was it without its profane movements and earthly delights.

We can see the pilgrimage in all its vitality at work in India today, where for the masses tourism is economically unthinkable. And we can immediately see undeniable similarities between the two institutions. Like tourist resorts, sacred shrines quickly acquire both economic and political significance. A tiny village or a solitary dwelling can grow into a sizable town once attention is drawn to it. To support a sizable body of itinerant pilgrims such growth is required, even though it may not be to the liking of the local residents. There are benefits and disadvantages to be had, so pilgrims are received with mixed feelings; like tourists, they are both welcomed and exploited. Pilgrimage in India, like tourism in the West, is the major cause of population movement. All classes are affected, all castes, and although the pilgrimage used to be largely restricted to the elderly, it is now increasingly popular among the young. As a social institution it allows for a temporary breakdown of otherwise inviolable barriers; to some extent it replaces old values with new ones that make a temporary rapprochement possible between otherwise socially segregated individuals and groups. Economic and political horizons are enlarged. For the wealthy, the pilgrimage functions somewhat like a tax write-off, except that the perceived reward for endowing pilgrim rest houses, or *dharmashala*, is more spiritual than economic. Such endowments make it possible for the poorest to travel: for some it is an escape from poverty or unemployment; for others, an escape from the confines of caste and community.

Until the very recent advent of the transistor radio, the pilgrimage was the only way that widely different segments of the Indian population could come to know each other, and that individuals, otherwise isolated for whole lifetimes in local communities, could get some kind of comprehension of the diversity and magnitude of their country. But in addition to serving very specific economic and political functions, the pilgrimage also allows for the fulfillment of personal goals, both secular and sacred. There are different kinds of pilgrimage, each offering different attractions, and choosing one is much like choosing where to go on vacation; you have to decide which of your needs most deserve fulfillment.

In any one community, for instance, there are usually a number of shrines that help bind the community together, and a visit to one or more of these is as much a social as a religious event. But farther afield there are pilgrimages to be undertaken that can last from a week to a year, and there are several major kinds of shrines to choose from, involving primarily either sacred places or sacred people. Places may be divided into two kinds, natural and man-made. Almost any natural wonder is likely to become a shrine, be it a mountain, river, cave, waterfall, hot spring, or even an odd-looking rocky outcrop. Such places become sanctified in myth and may even win scriptural mention, but it is more the simple attraction of nature and the desire to be part of something much vaster, more powerful, and more enduring that draw pilgrims to these places.

At some of these natural shrines great temples arise, such as Tiruvan-

If You Read Music... You'll Love Our Magazine

The Only Magazine You Can Play!

We call it SHEET MUSIC MAGAZINE. And that's exactly what it is! Each and every issue is filled with the most popular sheet music ever published, including *Pop, Great Standards, Jazz, Show Tunes, Folk, Country, Tin Pan Alley, Movie Songs, Classics, Ragtime, Blues,* and more.

When you sit down at your piano, organ, guitar, or any musicial instrument, *we want to be your music book!* And when you want to improve your own musical ability, we want our staff of writers to *show you how.* And in every issue they do just that! There are Keyboard Clinics, Guitar Workshops, Composers' Workshops, Sight-reading, Playing By Ear, Theory And Harmony, Rhythm Workshops, and so much, much more.

A single year's subscription brings you more than 100 great songs. And when you consider the price of sheet music these days, about $1.75 per song, and realize that Sheet Music Magazine provides the exact same thing for less than *15¢ a song,* you can understand why it has more subscribers than any other music magazine in the world today. A one-year subscription for $13.97 brings you over $175 worth of music!

And now you can choose between a *Piano Edition* and an *Organ Edition.* Each edition is specifically arranged for *your* instrument, and includes feature articles of special interest to *you.* Also, you can choose an *easy-to-play* version of the piano edition as well as the organ edition. The *easy-to-play* editions are especially good for you beginners and new students, young or adult, who don't think you are quite ready for the standard and special arrangements found in our standard editions. (If you are undecided as to which version would be right for you, we suggest you try the *Easy Edition.* You can change at any time, at no cost whatsoever.) Check your preference on the subscription application.

Let us send you your first issue with these wonderful songs... *All The Things You Are ... Canadian Sunset ... Hurting Each Other ... I Will Wait For You ... Make Believe ... Smoke Gets In Your Eyes ... They Didn't Believe Me ... Watch What Happens ... Why Do I Love You ... Yesterdays*

SHEET MUSIC MAGAZINE Dept. L1-10-71 352 Evelyn Street, Paramus, N.J. 07652

Please enter my subscription to Sheet Music Magazine and rush me my first issue with all the songs listed above. I understand that I may cancel at any time and receive a complete refund on all unmailed issues. No questions asked.

namalai in southern India. From the temple's rear walls a path climbs up Arunachala, a holy mountain said to be more ancient than the Himalayas. Elsewhere, temples were built because the site was sanctified by some sacred event. These monuments offer something subtly different from the natural shrines. There is a feeling of being a part of a vast congregation of believers—a member of a faith, of a corporate, rather than individual, body that is both physical and spiritual. It is a feeling that satisfies another kind of need.

The pilgrimage to people, rather than places, is different again. Sacred people, like sacred places, are associated with miracles, and while perhaps all pilgrims hope for some general kind of miracle—their transformation into something bigger, more powerful, more significant—there are some who hope for a specific miracle: the cure for an illness or the resolution of a problem. Both sacred places and sacred people may acquire reputations in this respect, but most people seeking some kind of specific assurance make the pilgrimage to one or another of India's great teachers, or gurus. Some pilgrims may seek even more from a sacred person. They seek their divinity—the ultimate transformation of their secular selves into sacred beings. Such pilgrims, once they find their teacher, devote themselves exclusively to the spiritual quest for the divine. There the parallel with tourism ends.

Pilgrims can be met on almost any train or bus or mountain trail in India, yet we might not recognize them as pilgrims; in most cases we would mistake them for travelers bent on personal pleasure. After all, most of their time is spent traveling to and from the shrine that is their sacred goal, and on the way they enjoy the excitement of travel just as we all do. They are seeing new places and meeting new people. New worlds are being opened up to them at each stage of the journey. This is true even for those who regard every step of the journey itself as a sacred act. The Indian pilgrim route is dotted with staging posts that become bustling commercial centers catering to the pilgrim's every need. For those who cannot get into the endowed *dharmashala*, there are hotels and restaurants. Small stores and roadside stalls overflow with trinkets and souvenirs, and the streets are filled with beggars selling the peculiar

ware of poverty, for even the poorest pilgrim will try to add to his store of merit by giving to others. Thus the beggars themselves are integral parts of the pilgrim scene, just as they are in many a tourist resort. There are also troupes of players, dancers, and musicians performing wherever they can find enough space, attracting large crowds of excited spectators. And of course there are other sideshows and even more secular forms of entertainment for the pilgrim ready to fall, temporarily, by the wayside.

Such pilgrim centers are graphic examples of the same process of dynamic fission and fusion, a kind of structured anarchy, that characterizes many tourist resorts. Most *dharmashala* are open to all, regardless of class or caste or even of nominal religious affiliation (I was as welcome in most Hindu *dharmashala* as Muslim and Buddhist pilgrims were), but in the larger and less remote centers there may be open discrimination, both regional and religious. It is a way of catering to those who wish to maintain a certain kind of ritual privacy and purity that is respected by others. And while some pilgrims are set apart, others who formerly had no unity are united. The pilgrimage encourages both the strict observance of orthodox rule and the relaxation of ritual regulations, and like tourism, it provides an opportunity for the open demonstration of extremes of both conservatism and free thought. Even at the shrine itself, where the pilgrim is reaching for his broadest identity, say, as a Hindu or as an Indian, there are ways in which he will be reminded of his equally vital but narrower loyalties to region, caste, community, and clan. Some regions, for instance, maintain at a center a resident priest (just as some maintain rest houses for members of their community only) who keeps a record of all pilgrims from his region, testifying to their sacred as well as secular allegiance.

But in the act of worship all secular differences are momentarily banished, and all unite in the realm of the sacred. And an experience need not be mystical to have considerable social consequence. The performance of *puja*, or "worship," the taking of a bath in the sacred tank, or hot spring, the sharing of consecrated food, these are all leveling devices. Afterward the distance is restored, but it is one of difference, rather than of superiority or inferiority. All this happens in any

Take part in the magic and excitement of the Royal Wedding

Facsimile of full-color Souvenir Book

The official Royal Wedding Souvenir Book

No couple has generated such worldwide interest or captured the hearts of so many. The marriage of a future ruling monarch is The Royal Event of the Century!

To commemorate this historic event, The British Collection offers in North America the British Post Office Royal Wedding Souvenir Book. The two actual British Royal Wedding Commemorative Stamps designed for this occasion are showcased on an 8″ x 8″ full-color album containing 16 pages of personal photos of H.R.H. Prince Charles and Lady Diana Spencer, plus past Royal Weddings. Even if you've never collected stamps, you'll take pride and pleasure in owning this magnificent memento of a once-in-a-lifetime event.

British stamps are among the most popular and sought-after philatelic items. As the first major stamp issue depicting this future monarch, the book could take on greater significance to collectors.

Among hundreds of commemoratives of the Royal Wedding, this is the *only* philatelic commemorative from Great Britain approved by the Queen. Because previous Royal Wedding commemoratives have sold very quickly, you are urged to place your reservation today.

tourist resort; it merely assumes another form.

Having last visited India thirty years ago (when I had come from Oxford on a two-year research fellowship at Benares Hindu University), on this trip I wanted to revisit some of the pilgrim shrines and the places and people I had known so long ago. With a young Brahman official from the great Birla Mandir (temple) in Delhi, I set off by train for Rishikesh, the stepping-off place for the famous triple Himalayan pilgrimage to Badrinath, Jumnotri, and Gangotri. Rishikesh, rather like the rest of India, seemed not to have changed at all in thirty years. As crowded as ever, the streets were filled with boisterous pilgrims and equally boisterous peddlers. The pilgrim season was ending and snow had already closed the shrine of Kedarnath, but even so we were lucky to find a small room in one of the poorer *dharmashala*. It was a typical pilgrim accommodation, an eight-foot-square cell with a clean cement floor and no furniture, only a small grass broom. Traveling as pilgrims, we each carried a blanket, a shawl, and a change of clothes that doubled as a pillow. Most pilgrims prefer unfurnished accommodations for reasons of both ritual and physical purity rather than because of any urge toward self-mortification.

A road of sorts now links Rishikesh with Badrinath, nearly two hundred miles into the mountains near the source of the Alaknanda, a major tributary of the Ganga River. At dawn, Mohan Kumar and I joined the crowd of pilgrims on the streets; about eighty of us managed to get on an ancient vehicle designed to hold a maximum of forty people. Luckily, I did not have a window seat. Even when standing I could see enough of the precipitous drop from the edge of the typically steep, twisting, mountain road to make me feel slightly nauseated. Landslides had swept parts of the road away, and every now and then the outer wheels of the bus dipped alarmingly as the driver negotiated the crumbling verge. Every week there are accidents; not infrequently, busloads of pilgrims fall to the rocky riverbed hundreds of feet below. On our trip, nobody seemed concerned; some passengers even joked about the possibility of "instant transmigration" if they were to fall into the holy river.

This denial of danger cannot be put down to religious fervor alone, although that plays a part. Indeed, some of the older pilgrims hope to die while engaged on a holy pilgrimage, and many journey to sacred places and stay there until they do die. Then pilgrimage becomes more like retirement than tourism. But the same devil-may-care attitude, from a touch of recklessness to the downright courting of disaster, characterizes many tourist and vacation activities, such as sports in which skills are tested as well as courage. For the passengers on the bus to Badrinath, the ride was also a test of faith.

Badrinath is high up in a steeply sloping valley, only a few miles from the Tibetan border. Ice-covered mountains fringe the near horizon, with Nilkanth reaching more than 21,000 feet. In October it was cold and windy but as yet free of snow. The site is not spectacular in any way; the sanctity of the place derives from its location on one of the major sources of the holy river Ganga.

The temple of Badrinarayan is on the far side of the Alaknanda River, across a wooden bridge. It is surrounded by stalls selling trinkets and souvenirs and special foodstuffs that are brought into the temple and blessed, then taken back home for distribution to friends and relatives. Inside the temple courtyard were other stalls occupied mostly by regional priests keeping a roll of all members of their community who came to Badrinath. Most of them had posted elaborate lists of the various *puja* they would perform and at what cost. Mohan Kumar was dismayed to find that he did not have enough money to pay for a *puja* of the kind he wanted. He tried bargaining but that failed, so he settled for something less and insisted on my attending and sharing the blessing with him, although he refused to let me share the cost. I was moved by his devotion and by his enormous excitement at having accomplished a pilgrimage that a very few ever make, and generally only in their later years. I might have been more moved by the *puja* itself, which I remembered well from long ago, but for the fact that a short distance away a number of pilgrims were clustered around a radio that was blaring a broadcast of a championship cricket match being played in Calcutta. I never did like cricket, and the precise English accent of the Indian commentator describing the action added, for

The World Wildlife Fund announces an original work of art in fine, hand-painted porcelain

Surprise!

Inaugurating the World Wildlife Fund's first collection of baby animal sculptures in porcelain.

Issued in a limited edition.

Art of exceptional charm and beauty, at the very attractive price of $45.

For the first time in its history, the World Wildlife Fund has undertaken the creation of a collection of porcelain sculptures of baby animals.

Surprise!, portraying a charming little tiger cub, inaugurates the collection. Crafted in fine hand-painted porcelain, it is a thoroughly delightful work of art. And it will be issued at the very modest price of $45—which may itself be paid in two convenient monthly installments of $22.50 each.

This new and original work of art has been designed for the World Wildlife Fund by Eva Dalberg, one of the world's most talented portraitists of animals. Dalberg was chosen for this commission because she has the unique ability to capture the lovable quality of animals.

Here the little tiger is portrayed in an amusing—and totally unexpected situation. With a bright green butterfly perched right on the tip of his nose! This delightful sculpture will be crafted in fine porcelain and completely hand-painted. So, all the colors and features will be clear, crisp and vibrant. The tiger's orange coat and black stripes, his sparkling black and yellow eyes, his striped tail—and, of course, that devilish little green butterfly.

Surprise! will be crafted for the World Wildlife Fund, under the supervision of Franklin Porcelain of Japan. Each sculpture will be crafted in Taiwan and will be backmarked with the official "WWF" symbol. In addition, a Certificate of Authenticity attesting to its official status and bearing the signature of the Director General of the World Wildlife Fund International, will be included.

In the tradition of classic works in fine porcelain, this enchanting sculpture will be made available in a limited edition, reserved exclusively for those who order from the collection of porcelain animal sculptures during 1981. When all valid orders from these individuals have been filled, the edition will be permanently closed.

You'll enjoy displaying this enchanting little tiger in your home and showing it to all your friends. It will be a conversation piece you will treasure. And you will have the satisfaction of knowing that it is created in a long-established tradition. For, of all porcelain pieces collectors prize, small figures of animals are among the most popular.

To reserve *Surprise!* by Eva Dalberg, you should act promptly. Please be sure that your Reservation Application is sent to the World Wildlife Fund, c/o Franklin Porcelain, Franklin Center, PA. 19091, by August 31, 1981.

RESERVATION APPLICATION

Surprise!

Valid only if postmarked by August 31, 1981

World Wildlife Fund
c/o Franklin Porcelain
Franklin Center, Pennsylvania 19091

Please accept my reservation for *Surprise!* by Eva Dalberg. This original sculpture will be crafted for me in fine hand-painted porcelain.

I understand that I need send no money at this time. I will be billed in two equal monthly installments of $22.50* plus $1.25 for shipping and handling, the first payment due before the work is sent to me.

*Plus my state sales tax

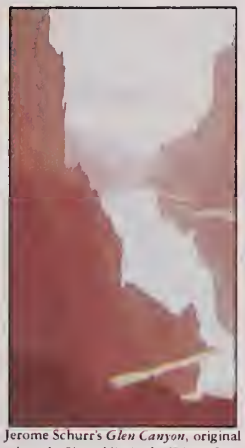
me, a note of falsity that I had not expected in so remote a shrine. Mohan Kumar laughed and said that if I were really a pilgrim, then I would not have even heard the radio, let alone been distracted by it. "By the way," he added, "what *is* the score now?" He was a little critical of me because I had not joined in the ritual bathing in the hot spring that fills a steaming pool right below the temple. I was reminded again of tourism. I had offended him, not because of any desecration, but because I was not getting my money's worth, not taking advantage of all the attractions available to me. But I could not escape from the feeling that I was in a deservedly unfrequented tourist resort and had to walk off into the hills for several miles before I could feel that for me, at least, this was a sacred, rather than secular, pilgrimage.

We all have individual ways of finding the sacred. Some find it in the company of others; some have to be alone or have learned how to isolate ourselves even when in a crowd. Others need something or someone, such as the builders of temples and cathedrals or the generations that have worshiped there before them, to mediate between the sacred and themselves. It is these pilgrims who flock to the man-made shrines. At Badrinath I found no one who had the slightest interest in making the pilgrimage to Jumnotri. Jumnotri and Gaumukh, beyond Gangotri, are for those who seek solitude. This was not Mohan Kumar's goal, but being curious and believing in the merit of right effort, he agreed to come to Jumnotri.



We had to return by bus and on foot to Rishikesh. There we hired a car and made our way as far as Hanuman Chatti—a day's walk from our destination—where we spent the night. Thirty years before, it had taken me four long days on foot to reach Hanuman Chatti. It is still just a tiny cluster of wooden buildings hanging on to a rocky ledge above the river, the pine-forested mountains rising almost sheer on all sides. The villagers continue to take in pilgrims, but now they offer thick, quilted bedding as well as drafty rooms. Before dawn the next morning, we set off on the narrow trail that leads up and up, with unpleasant stretches of path cut into the sheer rock face as much as a thousand feet above the river and with abrupt descents that are as alarming and exhausting as the ascents.

The last two or three miles are the worst, as though designed to test your faith. For me, with my fear of heights, the last cliff face traverse made me stop and consider, very seriously, just how much my life was worth. Halfway along the traverse, where the ledge follows the cliff around a jagged bend, the pilgrim sees for the first time one of nature's most magnificent shrines: the young torrent of water cascading down out of the snows and through the pine-covered gorge (crossed now by a wooden bridge that is more substantial than the old rope bridge that used to be there). On the near side of the bridge there is now a small rest house, a modern construction that seems quite out of place. Even more out of place was some colorful laundry hanging on a line, almost frozen stiff, and four figures in bright plastic slickers squatting on the ground at the entrance to the bridge, playing cards. They were European tourists on a three-week climbing holiday. In two days they had not crossed the bridge to the sacred shrine and hot springs on the far side. They did not even know that while the water on their side was icy cold, on the far side, fed by hot springs, it was warm enough to bathe in with comfort.

The plastic garments, the card game, and the visual pollution of the laundry, which I found so offensive, did not offend Kumar at all. His pilgrimage was not mine, his was public, not private. "They may think they are just on holiday, but if they enjoy climbing so much, why have they wasted two days here unless they are getting something else? Perhaps, for them, this side of the river is sacred." The tourists/climbers/pilgrims, as Kumar classified them, watched with amusement as we crossed the bridge and scrambled up to a cave above a small temple. Lal Bahadur, our driver, was not the least bit interested in the tourists; he was too busy smoking his last cigarette before he crossed to what he called the "good" side of the river.

I must have been a tourist thirty years earlier, for although I crossed the river then, I did not discover what the three of us discovered this time—each in his own way, each sharing his discovery. In the cave Mohan Kumar found the holy man of the cave and discovered that it was a sacred person rather than a site that he was seeking. We spent a long time in that cave. Lal Bahadur discovered

What your home could have in common with the Met, the Tate, and the Louvre

Jerome Schurr's *Glen Canyon*, original serigraph. Signed limited edition of 290.

Alexander Calder's *Jardin Fantastique*, original lithograph. Signed limited edition of 90.

Al Hirschfeld's *Charlie Chaplin 1*, original lithograph. Signed limited edition of 125.

Virgine Manzano's *Nude*, original lithograph. Signed limited edition of 350.

Cuca Romley's, *Central Park Fountain*, original etching. Signed limited edition of 170.

Wilbur Streech's *August Sun*, original serigraph. Signed limited edition of 250.

Marcelle Stoianavich's *Vacances*, original lithograph. Signed limited editinn of 225.

In your own home, you can exhibit original work by artists who are represented in the world's great musems and galleries.

Artists like Calder. Chagall. Dali. Miró. Picasso. Vasarely.

At the Original Print Collectors Group, we offer moderately priced limited edition prints by these and other well-known artists.

Our offerings include signed original etchings, engravings, and silk-screen prints.

Each print we offer is signed and numbered by the artist. Custom-framed. Accompanied by a certificate of authenticity and a full money-back guarantee.

And each print has been chosen not only for its beauty but for its investment value.

(Works by the artists we offer tend to appreciate, sometimes as much as 30% in a single year. Perhaps that's why *The Wall Street Journal, Business Week, Money,* AP, *Barron's* and UPI have quoted us as an authority on investing in art.)

For more information, send in the coupon. There's no obligation.

You'll find out about the special pleasure of owning original art, instead of just visiting it.

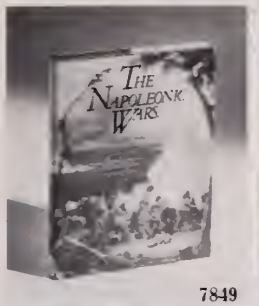
places where countless pilgrims had worn stones smooth as they worshiped. He discovered bells, outside the cave and inside the temple, and he rang them with exuberant joy. I discovered an unexpected natural shrine. Years before I had been enormously impressed by the hot springs that gush out of the rock, forming a little caldron in which potatoes and rice can be cooked in minutes; and I had been less impressed by the pools, lower down and less hot, in which pilgrims bathed. But I had not bathed; an Oxfordian prudishness has always made me nervous about nudity.

This time, however, while the food we had been given in the cave was cooking, Mohan Kumar said he was going to take a ritual bath, and from where we were, Lal Bahadur found that to get to the main temple, inconspicuously buried in the rock face, he had to go through a steaming pool. Suddenly I too was standing stark naked in the icy wind, and all three of us plunged into the hot water. We totally submerged ourselves, as much to unfreeze our noses as because it is ritually correct. When we came up for the third (ritually correct again) time, there was the disciple of the holy person of the cave, standing in the temple at the edge of the pool. With song and incense he was blessing us, blessing the water and the pine forests, blessing the whole world—including the card-playing tourists, I am certain. And there were the three of us, a Hindu Brahman, a Nepali Buddhist, and an Anglo-American agnostic, all equally naked and all equally blessed. The exhilaration was more than just the combination of altitude (about 11,000 feet), cold air, and a steaming-hot outdoor pool provided by nature. The nakedness had something to do with it, banishing the last illusion of distance and difference.

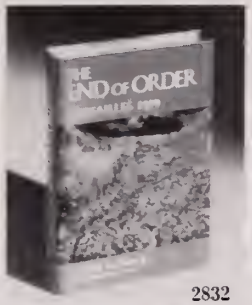
Mohan Kumar and Lal Bahadur did not come with me to Gangotri. The temples there had all been closed for the winter, and neither of them wanted to face the long walk beyond, to the face of the glacier from which the great Ganga pours, a place known as Gaumukh.



Gaumukh is probably the most inaccessible and the holiest of India's sacred natural places. The trail quickly climbs above the tree line. Suddenly, the massive snowy mountains that seem so remote when seen rearing up above the dark green pine forests are no longer remote; the snow is all around and there is nothing but rock and snow between you and the top of the world. The gorge, rising sharply, becomes an open, windy, shallow valley, with the river tumbling over rocks and boulders, the spray freezing as it lands.

The trail disappeared into a mass of enormous boulders, the size of two- and three-story houses, and the last mile took more than an hour of painful scrambling through the moraine, guided only by the sound of the river. Then, quite abruptly, the blue ice face of the glacier was right in front of me, and there was Gaumukh, the "mouth of the cow," a gaping black hole with stalactites and stalagmites of ice forming jagged teeth. Or was it, as some say, the head of the god Siva, the river pouring out of his tangled hair? In midstream a saffron flag had been erected on a pole wedged into the rocks. Having come this far, and too cold to be afraid, I made my way out. Reaching the rocks by the flagpole, I squatted down and dipped an enamel mug into the water, which if drunk at this place is said to give eternal life or release from it, whatever you choose to think. By the time I got the mug to my mouth the water had frozen inside it, and my fingers had frozen to the handle. A second dip, quicker this time, allowed me a couple of swallows, and the pilgrimage was over.

Except, of course, that it was not. Like tourists, pilgrims have to make their way home, be it from the crowded streets of a pilgrim resort such as Badrinath, from the cave of Bangali Baba at Jumnotri, or from the total solitude of Gaumukh where the rest of mankind has been left somewhere far below, far behind. And, also like the tourist, the pilgrim is not the same person that set out. For each there is a measure of transformation, intended and unintended. Something happens to both voyagers, largely to the extent that they are willing to let it happen, something that does more than rejuvenate, something deep and enduring. For each, one step further has been taken on the road to self-discovery, and the self is that much enlarged.



Colin Turnbull, formerly associate curator of African ethnology at the American Museum of Natural History, is visiting professor of anthropology at George Washington University.

Seeing Double and Seeing Triple

The images of far distant single objects appear to be multiplied in accordance with a phenomenon predicted by Einstein

by Stephen P. Maran

During the past two years, astronomers have been studying two quasars: one that looks double in photographs and one that looks triple. But it turns out that these multiple photographic images are simply cosmic proofs that appearances can be deceiving. In each case, there is only one real quasar, and we are, in fact, "seeing double" and "seeing triple."

Quasars are the so-called quasi-stellar radio sources. They emit intense radio waves, as well as much visible and infrared light, X-rays, and gamma rays. A single quasar, although not much larger than the solar system, may be thousands of times brighter than a whole galaxy of hundreds of billions of stars. Thus, quasars are the most energetic class of objects in the universe. As a class, they are also the most distant objects known (see "Quasars Confirmed," *Natural History*, February 1980), and they are very rare. Despite extensive surveys, fewer than 2,000 quasars have been found, and these are typically separated from one another by tens of millions of light-years.

Given such large separations, it was remarkable when what appeared to be a double quasar was found, with its two members, 0957+561 A and 0957+561 B, separated by less than 6 seconds of arc (or 1/300 the apparent diameter of the moon). This corresponds to an actual separation between 0957+561 A and 0957+561 B of only about 220,000 light-years.

The discovery of the apparently double quasar was made on March 29, 1979, by Dennis Walsh, a radio astronomer at the University of Manchester, and two quasar experts, Robert F. Carswell of Cambridge University and Ray Weymann of the University of Arizona. With the 84-inch telescope at Kitt Peak National Observatory in Arizona, they found that the two members of the double quasar have similar spectra. The same absorption lines and emission lines are present with the same strengths in the two spectra, and the quasars have the same red shifts as well. Emission lines are bright spots in a spectrum caused by radiation from specific atomic elements; absorption lines are dark places resulting from atoms that cut off light at certain wavelengths. The similarity in spectral lines and red shifts between the two quasars meant A and B (as I shall call them) were at virtually the same distance from the earth and had similar chemical compositions and physical conditions.

The similar spectra led some astronomers to believe that a true binary quasar system had been found. In other words, they thought that A and B were in orbit around a common center of gravity, like the two members of a binary star, and that they must have been born together through whatever process it is that makes a quasar. This was my reaction as well, and it occurred to me that the uncanny similarity of A and B was evidence for the relatively unpublicized "spinar" theory of quasars. According to this theory, the energy of a quasar is derived from a very massive, rapidly rotating object, or spinar. If a spinar spun too fast, it might well split apart, perhaps producing two identical quasars. This argument may sound logi-

THE NEW FX-D QUARTZ FROM YASHICA

Superior Precision Made Affordable.

Total *Quartz* Control, instantly and accurately captures all lighting situations.

True Automatic/Manual operation with 100% precise *quartz* regulation offers beautiful results, frame after frame.

Automatic Dedicated Flash with exact *quartz* timing makes for perfect flash photography, day or night.

Automatic Exposure Lock quickly and confidently freezes the action with extreme *quartz* precision.

Auto Winder Capability with the accuracy of *quartz* assures once-in-a-lifetime results.

Perfect *Quartz* Precision in a sleek, compact 35mm SLR is now an affordable reality. In fact, the new *FX-D Quartz* from Yashica offers the versatility and total accuracy only available in cameras costing far more. And further, this ultra-precise *quartz* timing extends to its electronic accessories.

Created by the pioneer of both electronic and *quartz* photography, the unique *FX-D Quartz* is designed to be an integral part of the world's most accurate, totally adaptable 35mm system with more than 300 technically advanced accessories including the new CS-201 automatic dedicated flash, auto winder plus a host of sharp Yashica and Carl Zeiss T* lenses.

Find out more about the *FX-D Quartz* at your local Yashica dealer.

Yashica *Quartz*, Symbol of Precision and Quality.

"IN JUST 10 DAYS, I'LL SHOW YOU HOW TO DO

$\int_a^b f \sum_{n=1}^{x} a_n$ **REAL MATH**

ON YOUR SCIENTIFIC CALCULATOR!" ★

•Quick. •Easy. •Guaranteed. •Fun, too!

INTRIGUED BY CALCULATORS? Then you can step up your math skills *fast!* Use my *new method* in guidebook form. It's called *CALCULATOR CALCULUS* and comes with this guarantee: *If after 10 days you're not astounded at the problems you're solving on your own calculator, return the guidebook for an immediate refund.*

But the point is - you won't want to send it back. For this is the *easiest, fastest shortcut* ever! The day you receive your copy in the mail you'll want to put it to work. It's that exciting and helpful.

My name is Dr. George McCarty. I teach math at the University of California. I wrote this guidebook to cut through the confusion. It does just that — with worked-out examples, simple exercises and practical problems — all designed to work with precision and magic on your calculator!

POWER METHODS. Need to evaluate functions, areas, volumes — solve equations — use curves, trig, polar coordinates — find limits for sequences and series? It's all here!

If you're in the biological, social or physical sciences, you'll be doing Bessel functions, carbon dating, Gompertz growth curves, half-life, future value, marginal costs, motion, cooling, probability, pressure — and plenty more (even differential equations).

Important numerical techniques? Those algorithms are here, too-rational and Pade approximation, bracketing, continued fractions, Euler's method, Heun's method, iteration functions, Newton's method, predictor-corrector, successive substitutions, Simpson's method and synthetic division.

LOOK AT WHAT USERS SAY: Samuel C. McCluney, Jr., of Philadelphia writes: *"CALCULATOR CALCULUS IS GREAT! For ten years I have been trying to get the theory of calculus through my head, using home-study courses. It was not until I had your book that it became clear what the calculus was all about. Now I can go through the other books and see what they are trying to do. With your book and a calculator the whole idea becomes clear in a moment, and is a MOST REFRESHING EXPERIENCE. I program some of the iterative problems you suggest and it always GIVES ME A THRILL to see it start out with a wild guess and then approach the limit and stop.*

Professor John A Ball of Harvard College (author of the book *'Algorithms for RPN Calculators'*) writes: *"I wish I had had as good a calculus course.*

Professor H. I. Freedman of the U. of Alberta, writing in *Soc. Ind. Appl. Math Review*, states: *"There can be no question as to the usefulness of this book...lots of exercises...very clearly written and makes for easy reading."*

C.B. of Santa Barbara says: *"Your book has given me much instruction and pleasure. I do not hesitate to recommend it. 'CALCULATOR CALCULUS' is a book that inspires the reader to understand everything down to the last detail. You seem to have put your heart into the teaching."*

I WANT YOU TO TRY THIS. So, if you act now, you can invest in *'CALCULATOR CALCULUS'* for only U.S. $14.95 (to USA or foreign: add $1 for shipping, or $4 by AIR; in Calif. add 90¢ tax).

★ **GET MY COMPLETE KIT,** with a TI-35 calculator, a 200 p. Student Math Book, *AND* the guidebook, *ALL* for $39.95 (to USA only: add $2 for shipping, or $5 by AIR; in Calif. add $2.40 tax). As pennywise Ben Franklin said, *"An investment in knowledge pays the best dividends."* GET STARTED NOW — Tax deductible for professionals.

NO RISK WHATEVER! Send for it today. Be sure to give me your complete mailing address with your check or money order. If you want to charge it (Visa or MC), tell me your card no. and exp. date. *Prompt shipment guaranteed.*

Thank you!

TEAR OUT AND MAIL TODAY

cal, but fortunately I did not go on record with it. Further evidence soon showed that the hypothesis that A and B were physically distinct objects was wrong.

If A and B were indeed two distinct quasars, at two different points in space, then sufficiently powerful spectroscopic observations would inevitably reveal differences in certain absorption lines in their spectra. Unlike the emission lines, these absorptions are not produced by the gases of the quasars themselves, but in the intergalactic gas in their general vicinity. In particular, due to the motion of the intergalactic gas, the absorption lines in the spectrum of A should have red shifts slightly different from those in the spectrum of B.

Shortly after the March 29 discovery, however, additional spectra of higher quality were obtained with the 90-inch reflector of the Steward Observatory (another facility on Kitt Peak) and with the Multiple Mirror Telescope, an instrument equivalent in light-gathering power to a 176-inch reflector, on Mount Hopkins, also in Arizona. These spectra verified with greater precision that the absorption lines of A and B have identical red shifts. Walsh, Carswell, and Weymann were then able to conclude with high certainty that A and B are not two different quasars. Rather (as the three astronomers had suspected from the first, despite the skepticism of many colleagues), the double quasar represents the first known case of gravitational imaging, or gravitationally focused images, a phenomenon predicted by Albert Einstein as a consequence of his general theory of relativity. According to this interpretation, A and B are but two different images of a single real quasar. The images are formed by a natural gravitational lens, in this case a giant galaxy with strong gravitation, which focuses and intensifies the quasar light, just as a convex lens, or "burning glass," serves to focus the sun's rays to ignite a fire.

Einstein apparently did not consider the possibility that some object other than a star might act as a gravitational lens. But one of his contemporaries, the late Swiss astronomer Fritz Zwicky, realized that galaxies might also produce observable gravitational imaging and that the phenomenon could be used to increase the effective range of observatory telescopes. In 1937, Zwicky published a calculation

Come share Costa Rica. From the lively town fiestas to the peaceful atmosphere.

Now 50% more for your dollar.

Peaceful Costa Rica is truly a country of contrasts. You can spend your morning walking a secluded beach and experience the thrill of a town fiesta in the afternoon.

If you choose excitement, Costa Ricans always have a reason to celebrate. A Saint's Day, a town fiesta, a bullfight Costa Rican style, or a carnival.

On the other hand, if you would rather escape from the hurrying world, there are plenty of places to get away. Volcanoes. Waterfalls. A jungle train. Peaceful beaches. And you'll experience a gentle hospitality that's hard to find anywhere else.

Three nights accommodations and a city tour start as low as $56 (IT1LR1PF38) per person double occupancy, plus air fare. And with Costa Rica's favorable exchange rate, now you get 50% more for your dollar.

For more information on Costa Rica, call your travel agent or write: COSTA RICA TOURIST BOARD, Box #E11, 3709 N. W. 36th St., Miami, Florida 33142.

we have so much to share

WE'VE GOT THE SYSTEM THAT CAN MAKE YOUR PICTURES AS CREATIVE AS THESE.

It's the Cokin Creative Filter System. And it fits virtually every 35mm camera made, plus medium format, movie, TV cameras and enlargers. And almost all the lenses that go with them. From 36mm to 82mm filter diameters.

The key is an easy-to-use inexpensive filter holder. Each Cokin filter snaps in and out easily. You can even stack them for multiple special effects. There are more than 100 accessories to choose from, including color filters, prisms, masks and linear shutters.

The Cokin Creative Filter System. It'll make any picture you take like no picture you've ever taken before.

To see what Cokin filters can do and how easy they are to use, send a check or money order for one dollar, made payable to Minolta Corp. We'll send you a 40-page booklet with 158 full-color examples of Cokin filters in action. Mail to: Cokin Creative Filter System, Minolta Corp., P.O. Box 600, Garden City, N.Y. 11530

showing that the focusing of light from a distant galaxy by a closer one would intensify the former's brightness by a factor of as much as 100. He pointed out that if astronomers could find such gravitational images, they would be able to explore the universe to much greater distances than otherwise possible, since very distant galaxies (which ordinarily would be too faint to be seen) would be intensified to the point of observability.

Despite Zwicky's "farsighted" suggestion, no clear case of gravitational imaging of one galaxy by another has ever turned up. Astronomers have, however, found another way to explore the universe beyond the distance of the faintest detectable galaxies: they discovered quasars. As I mentioned earlier, quasars are much brighter than galaxies and hence are detectable at greater distances. In fact, shortly after the first quasars were found in 1963, it was suggested that they were *all* gravitationally focused images. Specifically, it was proposed that quasars are not a unique type of cosmic object but rather gravitational images of the central cores of very distant galaxies. The suggestion did not pan out and, in fact, was never taken very seriously by most astronomers.

When Walsh, Carswell, and Weymann reported that they had found a pair of gravitational images, many astronomers remained skeptical. "Where is the lens?" they wanted to know. Existing photographs such as those from the Palomar Sky Survey did not show a foreground galaxy between A and B, nor did photographs taken specifically for this purpose in Arizona after the March discovery. The Walsh team expected that the lens galaxy would be midway between A and B, as seen from the earth, because the two quasar images are of nearly equal brightness.

It was not until November 1979 that astronomers at the California Institute of Technology and at the University of Hawaii succeeded in obtaining telescopic photographs good enough to reveal the missing lens. Sensitive electronic cameras made this possible. Surprisingly, the lens is not midway between A and B, but rather just slightly north of the southern quasar image, B. The lens is a very large elliptical galaxy, a member of a cluster of galaxies located less than halfway from the earth to the real quasar. As the light from the quasar travels toward the earth, it is deflected and

focused by the gravitational field of the lens galaxy, and it is also affected by the gravitation of the galaxy cluster as a whole. Because the lens is not a simple spherical object, not the perfectly shaped work of an optician but a real galaxy of stars, the light bending is more complex than the simple mathematical case that Walsh, Carswell, and Weymann had considered. Also, the B image is actually seen through the lens. These two circumstances account for the fact that the A and B images are not equally spaced around the lens galaxy.

During the year following the discovery of the double quasar, many radio observations were made of it. The most impressive results, however, were obtained in January and February of 1980, by means of a technique known as Very Long Baseline Interferometry (VLBI). In VLBI a celestial radio source is observed simultaneously with antennae at widely separated locations on the earth. The received signals at each antenna are recorded on magnetic tape, along with very precise timing information from an atomic clock. Then the tapes from the various observatories are collected and analyzed by computer. The net result is a measurement of the size and structure of the radio source, with a precision comparable to that which a single radio telescope could provide only if its diameter were comparable to the transcontinental spacing between the VLBI antennae.

The VLBI measurements of the double quasar were obtained with antennae in Germany, Sweden, the United Kingdom, and West Virginia. They showed that the two images, A and B, are not simply little round dots in the sky. Instead, each consists of a tiny bright core with an elongated jet extending to the northeast. Thus, the two apparent members of the double quasar are virtual carbon copies of each other, maintaining a precise resemblance even when scrutinized with the most powerful technique at the astronomer's command.

About a year after the double quasar was discovered, a second case of gravitational imaging was found. The team leader in this case was Weymann. Although by that time a number of astronomers were on the lookout for additional examples of gravitational imaging with galaxies and quasars, the second discovery was purely accidental. Weymann and several other observers were conducting routine studies of quasar spectra. While observing the fairly well-known quasar PG1115+08, Weymann noticed that during a moment of exceptionally good viewing, the blurry image on the TV monitor of the 90-inch Steward Observatory telescope suddenly resolved into three components. One member of this triple quasar is much brighter than the other two, and all three are within three arc seconds of one another, making them even more closely spaced than the two images of the double quasar. Once again, however, subsequent studies with the Multiple Mirror Telescope showed that the three apparent quasars have identical spectra and red shifts, indicating that this is indeed another sport of nature: three gravitational images of a single quasar to befuddle astronomers who have difficulty enough in accounting for the remarkable properties of even a single garden variety quasar.

Plant Parenthood

Before dispersing, most flowering-plant embryos become dormant. Are mother plants protecting themselves from hungry young?

by Robert E. Cook

The sight of an animal and its young evokes deep feelings in many of us, yet we seldom respond to plants in quite the same way. A mother plant clucking over her clutch of growing seeds is difficult to imagine. But in an evolutionary sense the provisioning of progeny is very similar in plants and animals: all mothers will partition nourishment and protection among their offspring in order to leave as many descendants as possible. At some point in the development of their offspring, all mothers must also negotiate the delicate process of weaning.

In 1966 the British evolutionary biologist William D. Hamilton suggested that the evolutionary interests of the developing embryo are not necessarily the same as the mother's. The mother's genetic future is best served by maximizing the number of her offspring that survive as successful plants in the next generation. Each offspring contains the same proportion of her genes. Therefore, she should distribute her resources evenly among her seeds so that each receives sufficient nutrition to provide an excellent chance of successful seedling establishment. Too much food in any one seed might diminish the prospects of all the others. Each offspring, however, may have a different interest. Because pollen is promiscuous, each embryo may have a different father. It will try to maximize its own success, regardless of the fate of its kin, by increasing its share of maternal sustenance at the expense of other offspring and the mother. The resolution of this conflict of interest between mother and child is known as weaning; in plants, this process is intimately bound up in the development of the seed.

Seeds are genetically complex and are not simply rudimentary plants waiting for an appropriate moment to germinate. Each seed does contain an embryonic individual, which acquired half its genes from the mother when she formed an egg and half from a grain of pollen. This embryo is analogous to an animal embryo, but a seed is more than a fetal plant. Surrounding the embryo is a genetically distinct tissue, called endosperm, that serves as the source of nutrition for the embryo. Endosperm, for example, forms much of the starchy pulp of corn kernels and the liquid milk of coconuts. Like the embryo, endosperm tissue is neither exclusively maternal nor exclusively paternal in origin. Unlike the embryo, however, it develops from the fusion of one pollen nucleus with two or more maternal nuclei. Genetically, it has at least twice as many maternal genes as paternal genes; in some species up to fourteen maternal nuclei fuse with one set of paternal genes to form the endosperm. Therefore, this tissue genetically approaches, but is not identical with, the maternal tissue that surrounds it during development. Finally, to guard its contents through the journey of dispersal, every seed also has a seed coat, a hard covering composed of several layers of outer tissue. Seed coats, as well as the fleshy fruits, pods, and hard shells of many species, develop from the maternal tissue of the flower; their particular qualities depend entirely upon the action of maternal genes.

If these genetically complex seeds were produced asexually, each offspring would be identical to its mother and sibs, and there would be no conflict of interest. In sexual reproduction involving different individuals, however, half the genes of each embryo arrive with the pollen and represent the evolutionary future of some other plant. A pollen grain contributes little energy to the raising of offspring; most nutrition is maternal. By being parasitic on the nutritional largess of the female, the paternal genes achieve equal genetic representation in the embryo while catching a cheap trip into the future. Under the influence of their paternal genes, individual embryos may demand more food than the mother is prepared to provide. The resolution of this conflict lies in the intricacies of seed development.

Traditionally, seed development has

been interpreted as a single, integrated process marked by cooperation between parent and offspring. A grain of pollen alights on the tip of a flower and begins to grow slowly down the stalk. Once the pollen reaches the ovary, its two male nuclei, each with half the genes of the father, enter the embryo sac and seek fusion with maternal nuclei. The rapid cell division that results from the union of one paternal nucleus with two or more maternal nuclei produces endosperm tissue, which is fed by the proliferating vascular structure of the adjacent ovular wall. The other paternal nucleus fuses with another maternal nucleus to create a zygote, or fertilized egg cell, which gradually commences growth. After numerous cell divisions, this embryo has developed two growing tips and one or two incipient leaflike cotyledons for the storage of nutrients. Rather than coming directly from the mother, much of the energy for the growing offspring comes at the expense of the endosperm. This tissue may be rapidly expanding close to the vascular supply while being digested by the embryo a short distance away. (In some species, such as beans and peas, the offspring eventually consumes all of the endosperm and occupies most of the future seed.) Gradually, the growth of the seed begins to slow down, the water content drops, and the outer coat hardens. According to this traditional view, the future seedling becomes dormant in preparation for dispersal; germination will occur later upon rehydration of the seed.

But is a phase of dormancy really necessary for proper seedling development? Ian Sussex, a developmental biologist at Yale University, and his students have suggested an alternative interpretation of seed development, which suggests that the roles of the mother and the offspring are somewhat in conflict. They see the formation of a new individual—from a fertilized egg to a growing, rooted shoot—as a potentially continuous de-

velopmental pathway of cell division and tissue differentiation. In most higher plants, however, the mother imposes a detour on the offspring that channels it out of growth and into a phase of dormancy and desiccation. There it must await a signal to resume growth. Germination, then, represents a return to the original developmental pathway.

Sussex divides embryogenesis—the formation of the embryo within the seed—into two phases. Initially there is a period of intense cell division, with relatively little increase in size, as the fundamental structure of the future plant is roughed out. During this time, endosperm tissue grows rapidly on maternal resources and surrounds the offspring. The second phase commences suddenly about halfway through embryogenesis. The water content of the embryo begins to fall. Cell division ceases completely, and the embryonic body proper stops development. The offspring starts to digest the endosperm, and its cotyledons, now rapidly expanding, begin to store the newly formed proteins and starch. Finally, the seed coat dries and hardens into a constraining, impermeable jacket. The imprisoned embryo must survive on its own reserves until released by hydration.

Germination reverses this process. The seed absorbs water rapidly, expanding its cells and cracking the encasing coat. The rudimentary root penetrates the gap, and cell division accelerates throughout the body of the embryo. The remaining food stores in the cotyledons begin to disintegrate and pass to the growing tips. Incipient leaves soon form, shedding the maternal covering and expanding into the light.

Does the mother plant really impose developmental arrest on her young during embryogenesis, as this view suggests? Sussex calls upon three kinds of evidence to sustain his interpretation. First, there are viviparous species, whose seeds germinate while still attached to the mother plant. The growing embryos of coastal mangroves, for instance, never enter the dormant phase of seed formation, germinating well before they drop into the tide to root in local mudflats.

A second kind of evidence comes from the biology of primitive vascular plants, which may roughly resemble the ancestors of modern seed plants. Like mangroves, the embryos of ferns do not require dormancy for successful development. Their entire reproductive biology, however, is interestingly different: ferns reproduce by spores rather than by seeds and the offspring does not actually grow on the body of the mother plant. Instead, a spore, carrying half the mother's genes, disperses on the wind and begins to grow some distance from the original stalk. Slowly, a rudimentary, heart-shaped plantlet forms. This plantlet may engage in an intimate nutritional association with an underground fungus or develop a green disk of photosynthesizing cells. When moisture becomes abundant, the plantlet forms an egg nucleus that also has half the mother's genes. An identical process leads to the production of sperm, or gametes. For fertilization to occur, these male gametes must swim through a surface film of water to a nearby plantlet. Sex is thus obligately associated with a wet habitat. The embryo commences cell division, differentiates leaves and roots, and completely crushes the small plantlet in the process of growth. Neither desiccation nor dormancy has any necessary part in this pattern of plant formation. The seed habit may have

The Soligor 80-200mm Expand Your Horizons By Getting Close.

You've got a terrific 35mm SLR camera, but not all of your shots are terrific. Some suffer from too much unwanted scenery, some from tiny people in big frames... shots that didn't work because your creative I.Q. was more than your *lens* could handle.

That's right, lens. But, Soligor has a solution: the affordable, innovative Soligor 80-200mm One-Touch Zoom + Macro lens that lets you and your camera turn blah into beauty.

Zoom in to crop out extraneous details. Bring your subjects up to 4 times closer than a standard lens can. Frame your shots exactly as you want them, and Soligor quality captures them faithfully. Create exciting portraits, instead of just pictures of people; capture a still life or sports action as the kind of picture you bought your camera to get; experiment with amazing close-ups, thanks to macro ability. And it's all so easy with Soligor's single One-Touch control for zoom, focus and macro.

If some of the zip has gone out of your picture taking, zip down to your Soligor dealer and try our 80-200mm on your Canon, Minolta, Pentax, Olympus, Nikon or other fine camera. Or, write for full information.

evolved from primitive plants with a reproductive biology much like this.

The most compelling evidence for Sussex's thesis, however, comes from the artificial culture of embryos. If a developing seed is carefully dissected under sterile conditions, its embryo can be surgically lifted out from the surrounding endosperm and maternal tissue. Removed from the influence of the mother, the embryo ceases storing proteins and starch in the cotyledons. When placed in the proper nutrient medium, it will suddenly begin to grow and form a plant with roots and leaves. This has been called precocious germination, and it can occur at any time during the second phase of seed maturation. This second phase—with its cessation of cell division in the embryo, rapid storage of proteins, and subsequent developmental arrest—is apparently a response to the influence of the maternal environment.

Closer inspection has revealed the agent of this maternal control. Sussex and his students monitored the flux of plant hormones in the developing embryo of the French bean seed. High concentrations of hormones known to stimulate cell division and expansion characterize early ontogeny; these are the same hormones found in the growing plant after germination. At the critical transition point in the middle of embryogenesis, a new and quite different hormone, called abscissic acid, appears and rapidly increases in concentration. This substance is known to inhibit certain kinds of biochemical processes and is often associated with drought-stressed plant tissue. The concentration of this hormone soon reaches a peak as the cotyledons become congested with nutrients and the embryo undergoes dehydration. Finally, the seed coat hardens, and the concentration gradually drops to a low level.

Some scientists believe that the abscissic acid is synthesized in the maternal tissue and transported to the embryo through the endosperm. Sussex, however, feels that the abscissic acid may be created by the embryo itself in response to a more fundamental signal from the mother, such as a gradual withholding of water. In either case, the certification of this hormone's role comes again from artificial culture. If an excised embryo is bathed in a nutrient medium supplemented with abscissic acid, precocious germination fails to occur. The

cotyledons proceed to swell, storing nutrients at a rate proportional to the concentration of abscissic acid, and the embryo becomes metabolically quiescent. The maternal influence has been simulated.

Abscissic acid, then, appears to be the chemical mediator of the developmental arrest imposed by the mother. It signals the impending desiccation of the offspring and initiates preparation for survival. It is a harbinger of stress, and it will serve a related function in the shoots of the adult. We know that its concentration increases in the leaves of drought-stressed individuals as the effects of declining water are felt. Ordinarily, water moves from the soil into the roots and through the vascular system of the plant to the surface of leaves, where it evaporates through small apertures called stomata. This liquid flow flushes each plant cell and provides the pressure that gives rigidity to stems and leaves. If soil moisture begins to decline at the roots, the lowered flow of tissue fluid leads to wilting leaves. At these times of declining water, however, the concentration of abscissic acid in the vicinity of the stomata increases, causing the surrounding cells to expand and close off the escape of fluid. With its internal pressure held constant, the plant can remain turgid while awaiting the relief of drought.

How remarkable that the embryo should respond in its own style to this messenger of stress. Yet this is nicely coincident with recent thinking on the origin of the flowering plants, in which embryo dormancy has undergone its most elaborate evolution. The great evolutionary biologist G. Ledyard Stebbins believes that the earliest flowering plants probably appeared more than 160 million years ago. Their origin is usually assumed to have been in the humid tropics, where there is often little seasonal variation in climate. Stebbins, however, argues that subtropical montane habitats, subject to seasonal drought, are a more likely cradle for flowering-plant evolution. Seasonality would greatly constrict the period of time permitting reproduction and would expose embryonic offspring to unfavorable conditions of drought. To survive, the embryo would require protection from imminent desiccation. Would not any individual able to respond to maternal signals of drought stress be more likely to survive to the next generation? The embryo's ability to store food and become dormant did indeed prove highly adaptive. This capacity also provided the mother plant with an incipient mechanism to control her growing young, which may have become essential for her own survival.

Indulge me, for a moment, in a bit of historical speculation on the evolution of the seed habit in the ancestors of modern flowering plants. Ferns, you may recall, are totally dependent upon free-flowing water for sexual reproduction. The male sperm must *swim* to the female egg that has formed in the small, rudimentary plantlet produced by a spore from the mother shoot. Such a system could not survive in conditions of even minimal drought; the plantlet alone would shrivel and die. The fertilization of the egg within maternal tissue solved this problem. Rather than releasing spores to the wind, the mother plant retained this stage within her own body, protecting it from desiccation. As a result, any seasonal declines in moisture no longer restricted reproduction.

But bringing the developing embryo into the safety of the maternal environment was not without its com-

WHETHER RAIN, FOG, OR SUDDEN SQUALL...
Swift Waterproof Binoculars Shine Through.

When weather conditions are less than perfect, see your way clear with Swift quality waterproof binoculars.

Seafarers are always prepared with Swift's **753 Sea Hawk Mark I** (7x, 50 I.F.–393 ft.–36 oz.), **717 Storm King Mark II** (7x, 50 I.F.–383 ft.–52.2 oz.), or the **717A Armored Storm King Mark II** (7x, 50 I.F.–383 ft.–53.6 oz.) aboard. All these fine binoculars feature a high relative light efficiency of 84.2, producing razor sharp images even during that unpredictable storm-at-sea.

Sports fans and ornithologists can enjoy the action even under the most adverse conditions when "armed" with Swift's quality waterproof glasses. The **752 Falcon Mark I** (7x, 35 I.F.) delivers a particularly wide field of view (525 ft.) and close focusing to 18 feet. Swift's **820 Armored Trilyte Mark III** (9x, 35 I.F.) offers maximum hand-held power in a compact (26 oz.) wide-field (383 ft.) instrument.

Swift also has an extensive selection of rugged waterproof riflescopes. So put on your rain slicker and enjoy the sights... with Swift's high performance waterproof instruments.

plications. Previously, the offspring's voracious appetite was confined to the consumption of the egg-forming plantlet, which lived independently of maternal nutrition. With the embryo growing in the mother's body, what was to prevent digestive incursions into maternal tissue while still permitting protection and measured sustenance?

I suggest that in the flowering plants, the solution was a "trust fund" established by the mother. The evolution of a nutritional intermediary, the endosperm, provided a zone of neutrality between the rich vascular supply of the mother and the omnivorous proclivities of the embryo. With this interposed tissue, the offspring never feeds directly on the mother's vascular supply. The extent of endosperm formation defines the nutrition of the embryo. The mother's final measure of control lies in the imposition of dormancy through the agency of abscissic acid. This hormone precisely regulates the digestion of endosperm and the storage of proteins and starch in the cotyledons, insuring that the funds of the mother's trust are properly spent in preparation for dispersal. With the water content of the seed dropping, the embryo desiccates and the surrounding seed coat hardens. Weaning is complete.

To heighten the narrative line of my essay, I have cast the characters of this evolutionary drama in stark roles of conflict and employed a script filled with a language of intent and purpose. In contrasting the interests of mother and young, I have implied that the embryo gained no advantage from the development of maternal control over nutrition and dormancy. The evolution of the modern seed was undoubtedly more complicated than this. For one thing, every successful offspring must become a parent itself. If it possessed paternal genes that caused it to feed too greedily as a child, the plant would eventually face similar demands from those of its progeny that inherited the genes. Perhaps this explains the evolutionary resolution of the conflict in favor of maternal control over nutrition and dormancy. We may never know. As always with evolutionary speculation about the past, we are forced to reconstruct history from its diminishing echo.

Robert E. Cook is associate professor of biology at Harvard University.

Mist That Thunders

Niagara Falls Ontario

Niagara. The very name evokes romance. Ride the 'Maid of the Mist'. Feel the earth shake beneath you, feel the spray like a tropical rain. Try a second honeymoon, this autumn.

World Famous McGUFFEY'S READERS

seven books that shaped a nation

Not just the primer—but the full set from primer through sixth grade . . . faithfully reproduced from the original engravings! Here are the books our great-grandparents used in that one-room schoolhouse. No fancy theories, no newfangled nonsense, no educational experiments—McGuffey's Readers mean business! (Could be that's why kids learned their 3 R's in those days!) Yes, first published in 1871, these books were the backbone of *Readin', Ritin',* and *Rithmetic!*

A fabulous acquisition for the serious collector. A joy for the whole family. Grandparents, Mom, Dad, kids . . . *everyone* will love a nostalgic look at this less complicated time, the gentle charm of the illustrations, the old fashioned simplicity of the texts. Truly a cherished gift.

The stalked eyes of this mantis shrimp from the Gulf of California (Hemisquilla ensigera californiensis) *provide it with excellent vision. This large species lives in burrows it excavates in the sandy bottom.*

The Hole Shrimp Story

A burrow in the sand or a hole in coral is of paramount importance to mantis shrimps

by Marjorie L. Reaka

Alex Kerstitch

It had been an exhilarating dive, eighty feet below the surface of Cane Bay, Saint Croix. My husband, Steve, several graduate students, and I had been diving in the bay to study the growth forms of deep-dwelling corals and the animals that live in and under them. We had seen gorgonian corals that looked like pipe cleaners, huge, platelike corals that drooped over the precipices, and multicolored fishes. The water was dark blue as we drifted over the coral-encrusted cliff, which drops 200 feet to the floor of the bay.

Upon our return to the West Indies Laboratory (which is affiliated with Fairleigh Dickinson University), we were told by Charles Seaborn, a professional underwater photographer, about an exciting find—a large sand-dwelling mantis shrimp had been observed in a burrow in a nearby bay. Although I had been studying the behavior and ecology of tropical mantis shrimps for ten years, I had never seen this rare species of *Lysiosquilla* in its burrow. Charles, Steve, and I immediately dashed off, our old Fiat rattling in protest, to observe and photograph the creature—a member of a lineage that diverged from other major groups of Crustacea about 400 million years ago.

The ancient Crustacea developed into a number of modern lineages, including the Stomatopoda (mantis shrimps), Isopoda (pill bugs or sow bugs), Amphipoda (beach hoppers), and Decapoda (true shrimps, lobsters, and crabs). The isopods and amphipods have eight pairs of walking legs. In decapods, these appendages have differentiated into five pairs of walking legs and three pairs of anterior mouthparts, or maxillipeds. The first or second walking legs of many decapods are modified into pinchers; in crabs, one first leg is dramatically enlarged as a claw, which is used to crush and scrape food, in complex displays, and in actual combat over shelter or a mate.

Stomatopods diverged from ancient crustacean stock earlier (in the

Charles R. Seaborn

Devonian) than these other lineages and have retained a different body organization, with only three pairs of walking legs and five pairs of anterior maxillipeds. Stomatopods also possess a primitive neural organization, with three pairs of ganglia, or groups of nerve cells, arranged in a row above the mouth. In contrast, in decapods, isopods, and amphipods, these groups of neurons are condensed into a compact "brain." In spite of the primitive arrangement of their ganglia, however, the stomatopods have strong learning abilities, highly active predatory habits, and a complex fighting behavior that is at least as sophisticated as that of the decapods.

The second pair of maxillipeds in stomatopods is modified into a pair of claws. Each claw, when open, exposes a series of teeth or a toothless blade with a needle-sharp tip, depending on the family to which a particular species belongs. In families where the claws bear serrated teeth, individuals use the appendages for snatching and holding soft-bodied prey such as polychaete worms and fishes. Mantis shrimps with snatching claws excavate burrows in mud or sand and attain larger sizes than those with bladelike claws. In families that have bladelike claws, the base of the last segment of the claw is swollen and heavily calcified. This type of claw is used as a hammer to smash hard-bodied prey such as snails, clams, rock oysters, and other crustaceans. Mantis shrimps with hammering, bladelike claws live in holes in coral or rocks and are restricted in their body size by the size of the available holes. These species are often more aggressive, more heavily armored, and more brightly colored than the species with snatching claws, which live in soft substrates.

The predatory, or raptorial, strike of the bladelike claws—almost too quick for the eye to see—bears a strong resemblance to that of the terrestrial praying mantis. This similarity is responsible for the common name of stomatopods, mantis shrimps. Although praying mantises and mantis shrimps evolved independently, on land and in the sea, their claw structure, their habit of waiting concealed to ambush unsuspecting prey, their stalked, mobile eyes and visually mediated behavior, and even their three pairs of walking legs are remarkably similar. Moreover, on the inside of each of their raptorial appendages, mantis shrimps, like some praying mantises, bear a colored spot, which they expose in threat displays. The mantis shrimps could well be considered the marine equivalent of the terrestrial praying mantises (or vice versa).

Mantis shrimps are found in all tropical and subtropical marine waters, but never in fresh water. Although one species is known from depths of more than 3,500 feet, most species live in shallow habitats less than 100 feet deep. Considered a delicacy in many cultures, the shrimps represent an important fishing industry in the Mediterranean, and their claws are prized as fishhooks in many areas of Oceania. Their bellicose nature, as well as their delectability, has earned mantis shrimps additional names in many languages. They are called "split toe" or "split thumb" in the West Indies, "pica" in Mexico and Central America, "shako" in Japan (where they are common in fish markets), and "vako" in the Gilbert Islands.

The mantis shrimps' claws are used not only for catching food but also for defense, as any diver who has placed a finger near the entrance to

This eight-inch-long mantis shrimp, left, and the author engaged in a gentle tug of war over some tidbits of squid. The mock battle took place in the waters off Saint Croix; the author never quite succeeded in luring this rare species, Lysiosquilla glabriuscula, *completely out of its burrow, below left. Iridescent color spots on the posterior appendages (uropods) of* Hemisquilla ensigera californienses, *below, can be used to startle potential predators.*

Alex Kerstitch

one of their burrows can testify. I have more than once retracted my hand from an unsuspected coralline domicile with the point of a mantis shrimp claw embedded in my finger—and with the fierce defender, less than two inches long, dangling from my hand. Divers are said to have had their fingers cut or even sliced off by individuals of a large species of mantis shrimp (up to ten inches in length) that occupies burrows in muddy substrates off southern California and Mexico.

Other notable characteristics of these ancient marine creatures are their bright coloration and elaborate fighting behavior, particularly in coral-dwelling species. Oval flaps protruding from anterior and posterior appendages (antennal scales and uropods, respectively) are often iridescent blue, red, or yellow and fringed with conspicuously colored hairs (setae). Body segments are often edged in brilliant red, and background body coloration may vary from chartreuse, emerald, carmine, speckled brown, orange brown, or lemon yellow to black with yellow stripes—even among individuals of the same species. In some species, particularly those in less aggressive families, all individuals are similarly colored. The function of different body colors among individuals of a species is not known, but such variation may allow longtime neighbors to recognize each other and hence avoid fights, may confuse predators, or both.

All mantis shrimps have an indentation on the inside of each raptorial claw. In the most aggressive species, this indentation is marked with a brilliantly hued "eyespot," which can be orange, vermilion, royal purple, powder blue, yellow, rose pink, or magenta. In other species, especially those belonging to less aggressive families, the spots are pale green or white. While body coloration varies considerably among individuals of some species, the color of the eyespot on the claws is identical on all individuals within a particular species.

In one of their most conspicuous threat displays, mantis shrimps lower and spread their claws, exposing the eyespots; at the same time the other, smaller maxillipeds (usually yellow, but sometimes white or iridescent blue white) are spread wide, and the head is reared back, with the antennae and antennal scales extended to the side. This display, used with interlopers, potential predators, and prospective mates, serves both to suddenly show the eyespots and to increase the apparent size of the shrimp.

Many organisms, including butterflies and fishes, are also known to startle predators by suddenly exposing conspicuous eyespots on some part of their body. The spots on the claws of the mantis shrimps, however, serve more than one function. The unvarying color of these spots within a particular species suggests that they convey information on species identity. Several species of mantis shrimps with similar morphologies often live in the same local habitat. The most aggressive species bear the brightest-colored spots. It is advantageous for members of an aggressive species to have some identifying, warning characteristic so that members of subordinate species can recognize and avoid them; thus the dominant shrimp is required to engage in fewer potentially damaging fights. The subordinate shrimp also benefits from recognizing the spots of the dominant species, as it can avoid a fight it would probably lose. Furthermore, members of subordinate species benefit from being less colorful because brightly colored spots could elicit an attack from a member of a dominant species.

In addition to the eyespot display, mantis shrimps direct aggressive behavior against other stomatopods that is remarkable for its rapidity and intensity. The shrimps smash opponents with the armored bases of the claws and spear them with the opened blades. These animals fight to the death in some cases, and individuals bearing characteristic wounds are frequently collected in the field. Most of the blows are not lethal, however, because each opponent rolls up into a ball, thrusting its armored tail toward the other like a shield. The opponents' blows frequently strike each other's shields, but rarely cause damage. Each of the coiled shrimps threatens and strikes over its shield, and

Polychaete worms, such as Hermodice carunculata, *right, share the same coralline habitats as mantis shrimps. Crabs of the family Majidae, below, are common prey for mantis shrimps living in coral reef rubble and back reef habitats.*

Charles R Seaborn

the two whirl and trade blows at a breathtaking pace. In the accounts of such fights that I tape-recorded as part of my research, I frequently sound like a sportscaster. As a pair of fighting mantis shrimps performed as many as 500 different aggressive acts during a ten-minute bout, student friends rooted for favorite warriors.

Extreme aggression creates social problems for the mantis shrimps. Like all crustaceans, they must shed their hard outer skeleton in order to grow. During the molting period, the shrimps are immobilized, soft, and thus vulnerable to predators, particularly other mantis shrimps. In fact, cannibalism of newly molted shrimps is common if the molted individuals have no refuge. Nevertheless, mantis shrimps have developed a variety of adaptations that decrease the dangers associated with molting, including sealing their burrow entrances with pebbles; a reduced period of incapacitation compared to other, less aggressive crustaceans; molting late at night when other mantis shrimps are inactive; and synchronous molting (in association with lunar cycles).

Their aggressive behavior also imposes a solitary existence upon mantis shrimps, except for a brief mating period when males and females manage to live together. Males apparently probe various burrows until they find a female sufficiently receptive to permit their entrance. Courtship is an elaborate affair, replete with threat displays that involve exposing the species-identifying eyespots. Aggressive acts, such as lunges and strikes, and defensive coiled stances gradually diminish as the pair become conditioned to each other by courtship displays and body contact in which the two glide past each other in the burrow, their sides touching. Before mating, the male massages the female's back. During copulation, he constantly scratches her anterior thorax with a small, brushlike first maxilliped. Courtship and mating continue in the burrow for several days until overt aggression reappears; eventually, the female evicts the male from the burrow.

In the next few days the female lays a batch of eggs (ranging from fewer than a hundred eggs in some small species up to many thousand in large species); then for more than a month she will abstain from food while she carries the compact mass in her maxillipeds. By constantly kneading and cleaning her brood, the female protects the developing embryos from microorganisms that would foul and kill them if she abandoned the egg mass for more than a few hours. The small larvae hatch and remain with the female in her burrow for several days to a week before they emerge and swim away. Like many other tiny organisms subject to predation by plankton-eating fishes, the transparent, spiny mantis shrimp larvae migrate to the surface to feed when the fishes are less active, just after sunset and before dawn; during the day the larvae hide near the substrate. The larvae bear raptorial spearing claws, and prey on other, smaller nocturnal plankton.

The evolution of the intense aggressive behavior of mantis shrimps has been linked to their occupation of burrows. Most fighting occurs in and around burrows, suggesting that they are a critically important and limited resource; when the shrimps venture forth from their protective burrows they are subject to predation by fishes. As might be expected, then, those species of mantis shrimps that inhabit preformed holes in dead coral or rocks are more aggressive than species that dig burrows in mud or sand and need not depend on an existing supply. Larger holes in coral are less common than smaller ones, and larger individuals within stomatopod species have also been observed to be more aggressive than smaller individuals. Similarly, among related coral-dwelling species of mantis shrimps, larger species are often more aggressive (and have brighter-colored spots) than smaller species.

Mantis shrimps that dig burrows must spend considerable time and effort in excavating, all the while exposing themselves to predators. Thus, these burrows are costly and, like preformed ones, worth defending. As a result, even shrimps that live in excavated burrows in soft substrates are considerably aggressive, although ag-

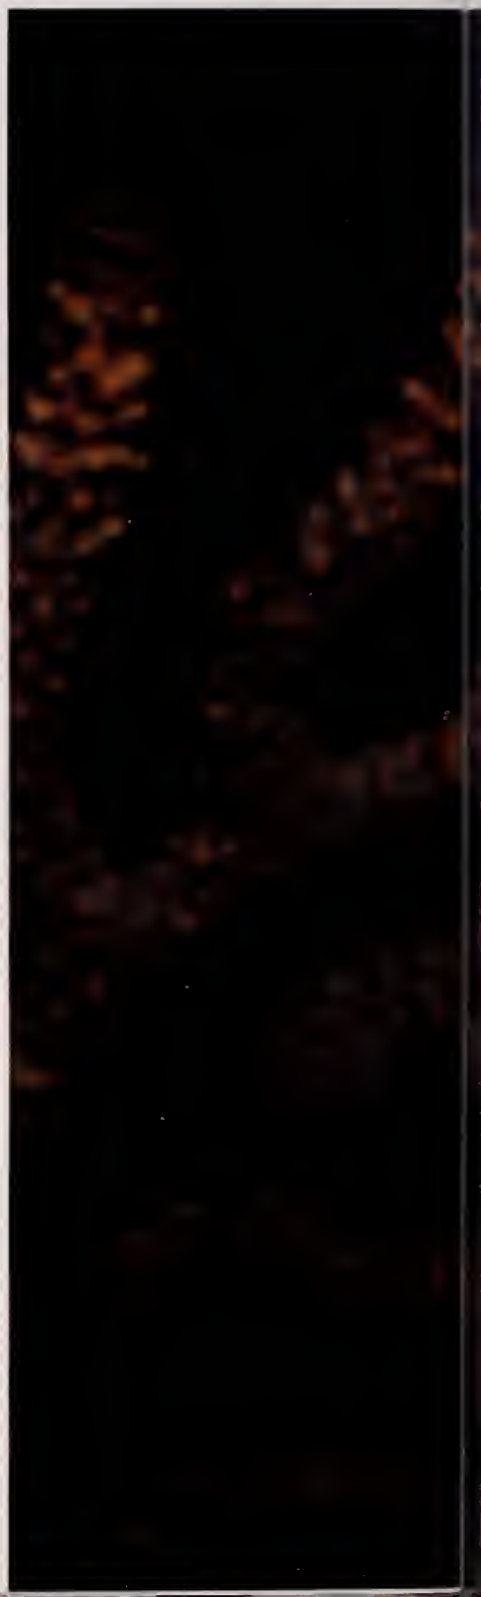
Charles R Seaborn

gressive behavior and associated skeletal armature are much more developed in shrimps limited by nonexpandable holes in coral or rock.

The giant mantis shrimp discovered by Charles and his friends was a *Lysiosquilla glabriuscula*. The species in the genus *Lysiosquilla* include some of the largest known stomatopods, attaining sizes of up to fifteen inches. Characterized by toothed claws and broad black-and-white or black-and-yellow bands across the body, these species are rare, and little is known of their habits other than that they dig vertical burrows in sandy substrates.

The discovery of this large *Lysiosquilla* was intriguing since we had been studying one of the smallest species of sand-dwelling mantis shrimps, *Nannosquilla schmitti*, in a nearby bay. Adults of the latter species are white and only about three-fourths of an inch long. When placed on a fine, sandy substrate, one of these petite shrimps will begin digging with its pleopods—abdominal flaps that beat rapidly, propelling a cloud of sand behind the animal. As a depression is formed, the shrimp arches the middle of its back downward; then it dips the anterior part of its body into the depression, gathers a load of sand in its maxillipeds, and flings the particles away, thereby enlarging the hole. This action is repeated until only the tip of the animal's tail clings to the rim of the burrow while its long, thin body hangs head-first down into the hole. Turning sinuous somersaults inside the burrow (which is scarcely wider than its body), the shrimp continues to gather sand, then emerges head-first at the surface, and flings the sand onto the small mound accumulating outside the entrance. Often the shrimp hesitates, peering in various directions with its mobile stalked eyes, which rotate independently as it surveys the surroundings, then somersaults again into the narrow burrow. The large *Lysiosquilla* had presumably excavated its burrow in the sandy bottom of the bay in a similar manner.



Recent studies conducted by Raymond Manning of the Smithsonian Institution and myself have shown that lineages of small stomatopods evolve more rapidly than lineages of large stomatopods. A few closely related species of *Lysiosquilla* are found in all the world's oceans, suggesting an old and slowly evolving group. *Nannosquilla*, however, is found only in the Americas, and all fourteen small species of this lineage have diverged into distinct species in either the east Pacific or west Atlantic regions since the elevation of the Central American land bridge about three million years ago. We found that these trends in evolution held up in all groups of stomatopods.

I thought about this varied evolutionary history as I lay on the sandy bottom of the bay peering at the iridescent yellowish green eyes, rudder-like antennal scales, and folded raptorial appendages of an eight-inch-long mantis shrimp. It returned my stare, rotating first one eye, then the other, appearing unconcerned in its two-inch-wide burrow. Charles had been directed to the shrimp by friends who were living on a sailboat in the area. Keen observers of the organisms living around them, they had watched the shrimp as it cleaned its burrow and performed its daily routines. As already suggested, mantis shrimps learn rapidly, and this individual had quickly become accustomed to its observers. Our friends had supplied us with some pieces of squid, and reassured by the serene appearance of the shrimp watching me, I extended my hand and the piece of squid toward

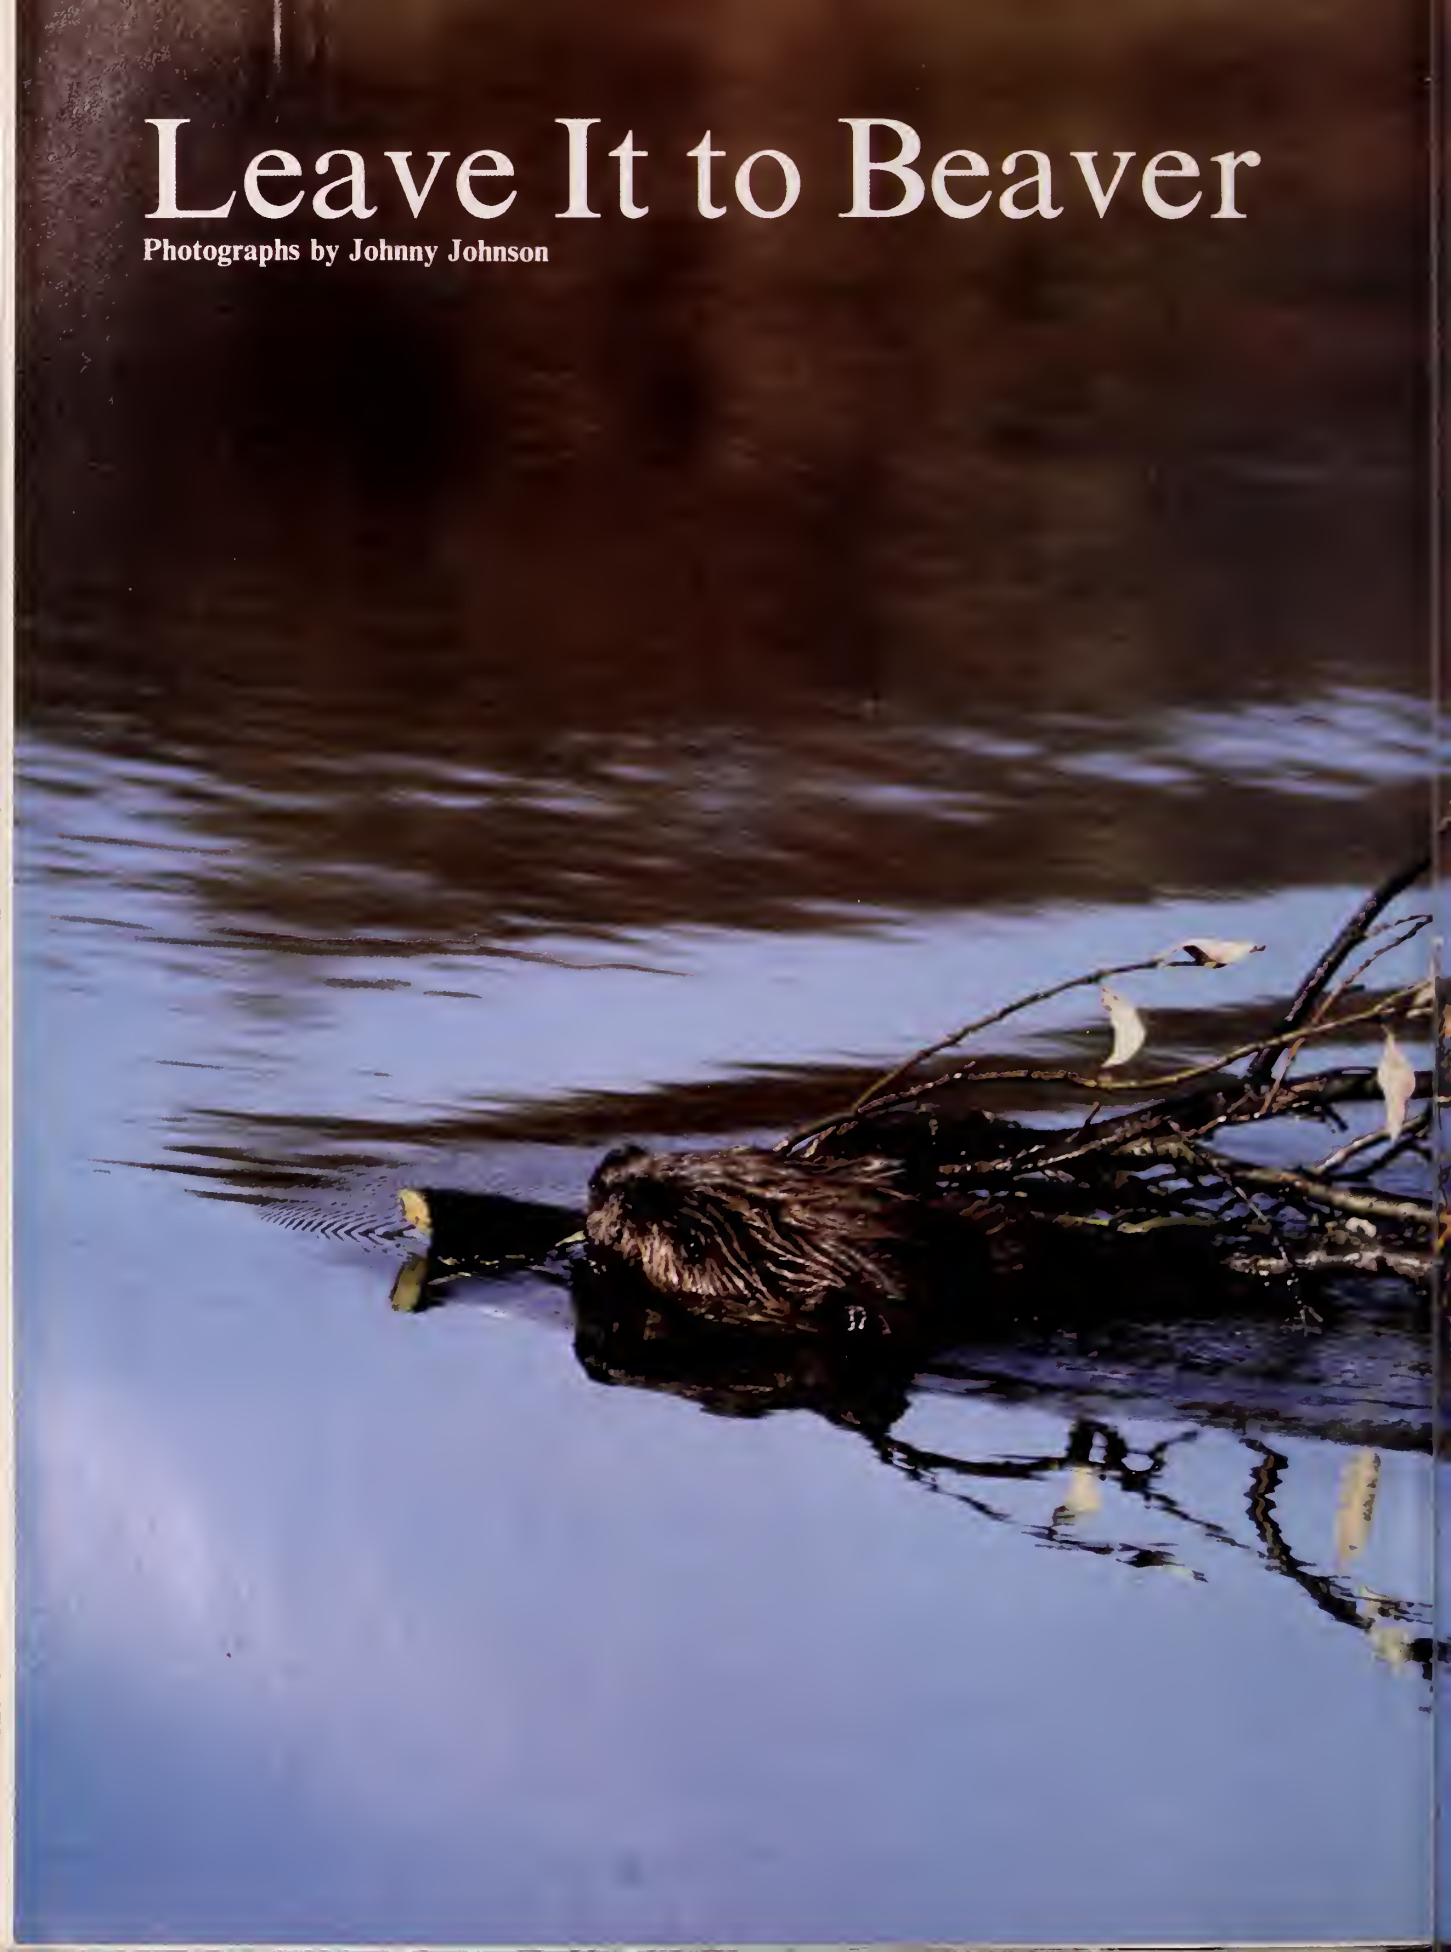
Charles R. Seaborn

The claws and anterior appendages of this Lysiosquilla glabriuscula *are spread wide in a threat display. Appearing larger than it really is because of the display, the shrimp is backing away from the author and descending into its burrow.*

it. Like a flower unfolding, the shrimp raised its black-and-white barred body and moved toward my hand, spreading its raptorial appendages in a threat display, and then extended the delicately brushed maxillipeds, reaching, grasping, sensing the meat. It caught the edge of the squid and pulled with surprising strength toward its burrow. We engaged in a tug of war, the shrimp attempting to sequester the delectable meal in the depths of its burrow, while I tried to entice it to leave its burrow so that we could see its entire body. I never totally succeeded, as the shrimp always clung to the edge of the burrow with its tail. Eventually, it pulled the piece of slippery squid from my hand and slid out of view in the burrow. I looked at Charles in dismay, afraid that we would get no more photographs of the marvelous animal.

After its meal, however, the shrimp reemerged to peer at us. I offered another slice of squid, and this time I was determined to retain it. After considerable tugging, the shrimp investigated my hand, gently enfolding it within the raptorial claw. The shrimp tapped, touched, tasted, and gently stroked my entire hand with the dainty maxillipeds, then returned to its tactic of tugging at the bit of meat, pulling this way and that, until it again retreated into its burrow. Once inside the shrimp resumed peering at me, its two large eyes rotating until it emerged for another attempt. We engaged in this contest over the squid appetizer for more than an hour. Never did the shrimp strike a blow to my hand with its powerful raptorial appendages. Once, forgetting caution for a moment, I reached out with my other hand to touch the animal as it leaned far out of its burrow for the shred of squid. Without haste, it slipped smoothly beneath my hand and back into the burrow. I soon overcame my chagrin, however, for the shrimp reemerged, seemingly undaunted, to seek more squid.

When we finally left the giant mantis shrimp, only its yellow eyes protruded from the burrow. The shrimp had retained its independence to the end, never having left the security of some contact with the burrow; it had endured with equanimity the intrusion of large, glass-faced, bubbling monsters and had taken our token offerings of squid. We left, elated by our good fortune at having shared an afternoon with such a magnificent, solitary creature. □



Squilla tiburonensis *uses its spearing claws to snatch soft-bodied prey. It inhabits the coastal waters off the province of Sonora, Mexico.*

Alex Kerstitch

Leave It to Beaver

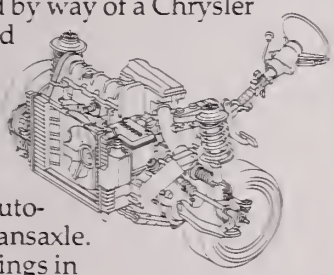
Photographs by Johnny Johnson

Winter comes early to Mount McKinley National Park in Alaska. By September, when these photographs were taken, light snowfalls occasionally dust the countryside, and the vegetation has assumed the colors of autumn. In a few weeks, blasts of frigid Arctic winds will sweep the landscape, locking the area's plant and animal life in cold storage.

Beavers have evolved a variety of techniques for coping with the difficulties and dangers imposed by a long winter. In particular, by constructing dams, lodges, and canals and storing food, these animals are able to deal admirably with hard winter conditions. Dams, usually built to blockade streams, create the ponds that are necessary as refuges from predators, conduits to float food and building materials, and sites to store food for use in the winter.

In preparation for the coming winter, this beaver is transporting willow branches to a cache in the pond. The branches will be anchored to the bottom, where they will stay until needed by the hungry rodent. Passing the winter in the security of its lodge, the beaver simply swims under water to the nearby cache and consumes enough willow bark to satisfy its needs. Then it's back to the lodge and its insulated environment, safe from howling winds, subzero temperatures, and prowling predators. It is this scenario that, in a couple of months, will be replayed across the frozen reaches of the North.

Dodge Omni Euro-Sedan



Dodge Omni Euro-Sedan: The power of a Chrysler engineered Trans-4 engine brings a new level of performance to America's first small front-wheel-drive automobile.

After years of research and development, the engineers at Chrysler introduced the advanced technology of front-wheel-drive to a small American built car. The Dodge Omni. That was 1978. Since then, more than 19 billion miles of owner experience with a full line of front-wheel-drive cars has been logged. Now the performance capabilities of a Chrysler built 2.2 liter Trans-4 engine creates a sporty new breed Omni. The front-wheel-drive Dodge Omni Euro-Sedan.

2.2 liter Trans-4 engineered for economy and efficiency.

Over half a century of experience designing and building some of the finest engines in the world went into the all-new Chrysler built Trans-4 engine. 135 cubic inches of displacement in a car that weighs under 2200 pounds puts a lot of power at your disposal. Designed specifically for front-wheel-drive, the engine is transversely mounted between the front driving wheels. The power of the Trans-4 gets to the road by way of a Chrysler designed 4-speed manual as well as a new 3-speed automatic transaxle. The savings in weight contributes to its impressive fuel economy.

41 est. hwy. 25 EPA est. mpg.* Fuel efficiency enhanced by advanced computer technology.

Chrysler's Electronic Fuel Control System means the Omni Euro-Sedan has an engine with a "brain." 7 sensors monitor engine functions, continuously adjusting the timing of spark plug firings and the air to fuel ratio. At all times, this electronic brain is making split-second decisions, while you drive, for the most efficient operation of Omni Euro-Sedan at all times, with minimum fuel consumption.

So easy to service, you can do it yourself.

You'll appreciate Omni Euro-Sedan's ease of servicing. Most major service parts on the Euro-Sedan's engine—oil filter, distributor, plugs, even fluid reservoirs—are right up front and easy to reach.

Omni Euro-Sedan represents the quality Americans demand.

Omni Euro-Sedan, like all new front-wheel-drive Chrysler built cars, is built in one of the most technologically advanced plants in the world. Computers keep a watchful eye during the assembly process. Robots perform most of the welding on the body and chassis to insure durability. Electronic consoles monitor 37 different functions of the engine with 66 tests. What's more, before the car can leave the line, it must go through and pass more than 2000 quality checks.

Dodge Omni Euro-Sedan only $6722**

Omni Euro-Sedan's base sticker price includes its 2.2 liter OHC engine, black bumpers and sill moldings. Cast aluminum road wheels. Sport steering wheel. Sport high back bucket seats.† Rallye Instrument Cluster that includes tachometer and electric clock. Black remote control mirrors.

Dodge Omni Miser. $5499 50 est. hwy., 30 EPA est. mpg.***

You might consider the Dodge Omni Miser. The lowest priced, highest mileage automobile built by Chrysler. Yet Omni Miser has an appreciable level of standard equipment which includes a specially calibrated 1.7 liter OHC engine and 4-speed manual transaxle. Rack and pinion steering. And front disc brakes.

Dodge

The New Chrysler Corporation

*Use EPA est. mpg for comparison. Your actual mileage may vary depending on speed, weather and trip length. Actual highway mileage will probably be lower. **Sticker price excluding title, taxes and destination charges. WSW $61 extra.
†Optional low back bucket seats as shown $43 extra. Buy or lease at your Dodge dealer.

The Origin of High Andean Birds

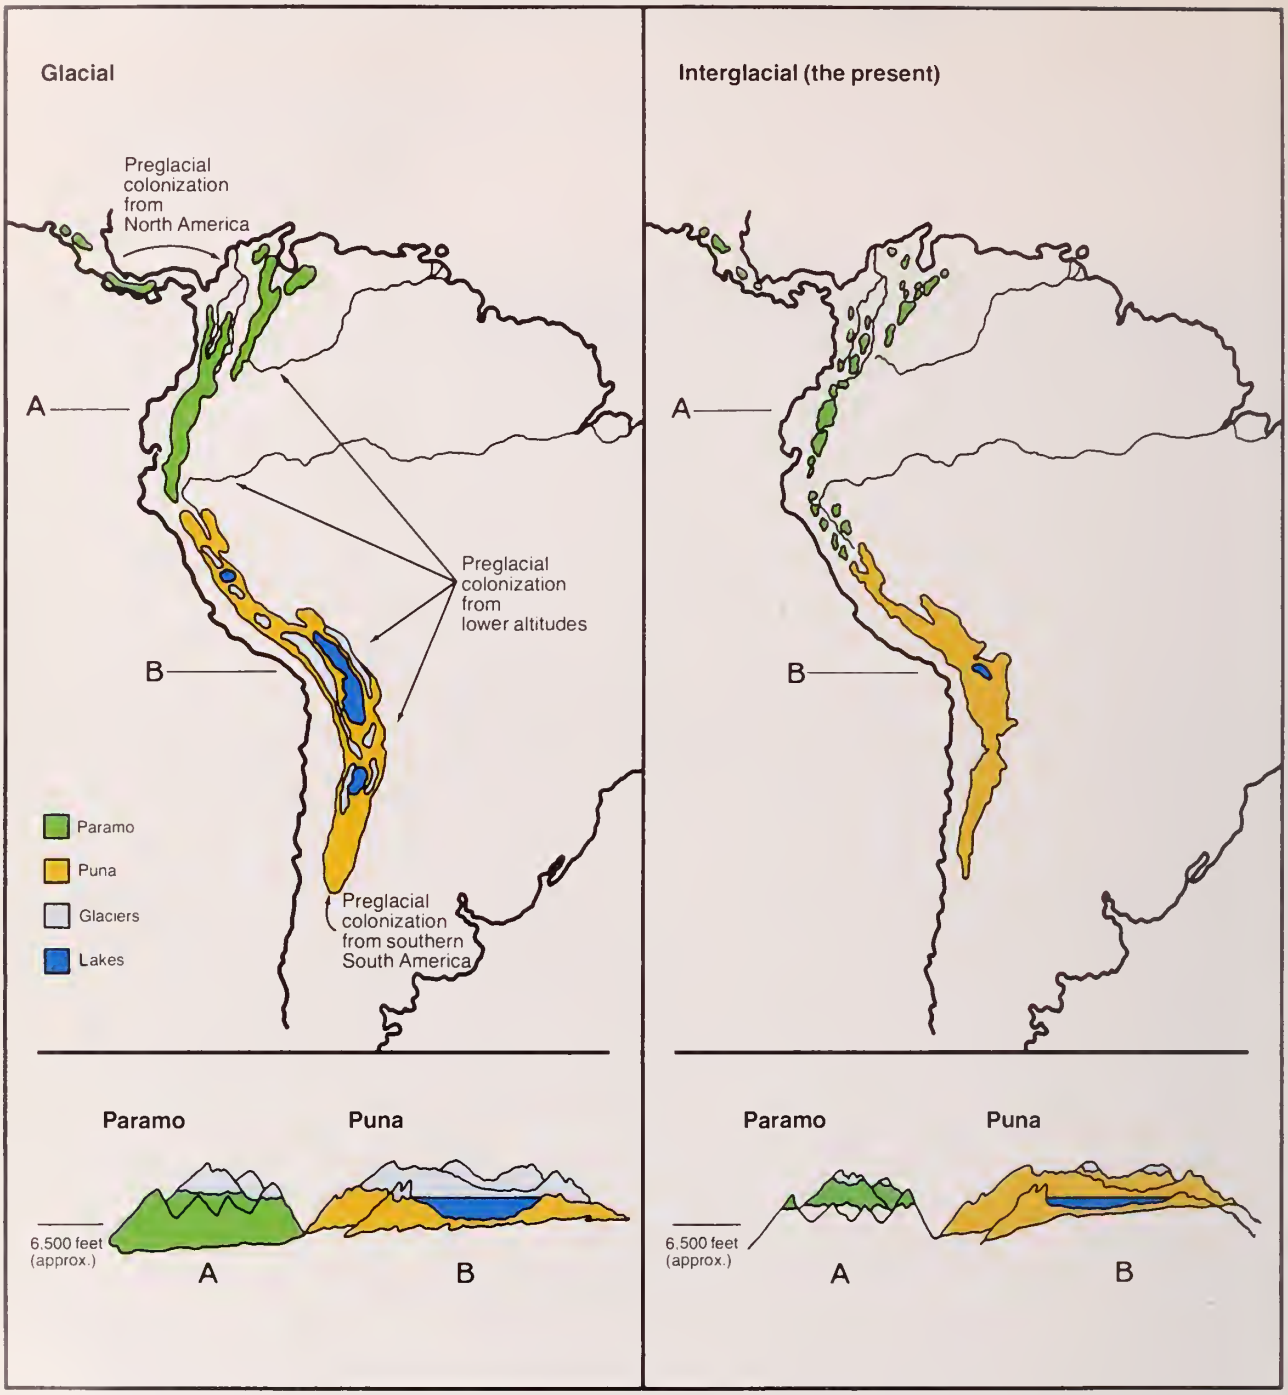
Biogeographers attempting to explain the complex history of birds living in the high Andes of South America must be part scientist, part detective

by François Vuilleumier

Breathtakingly beautiful at times, with a palette of bright colors under the hot, midday sun, but forbidding at others, with strong winds, hailstorms, persistent fogs, and the numbing cold of early morning, the high-altitude realms of the Andes continue to draw me back. Since 1964 I have made six expeditions, totaling about twenty months, that have taken me all along the Andean backbone, from Venezuela to northern Patagonia. Why? Because the Andes are, as ornithologist Frank M. Chapman put it half a century ago, "A New World."

Geologically recent, this narrow, 4,000-mile-long mountain chain provides the biogeographer with a wonderful setup for inquiries about fundamental evolutionary problems. The paramos of the Venezuelan and Colombian Andes—wet, grassy alpine-like areas extending from 10,500 feet up to the snowline—are islands of open vegetation separated from each other by lower-altitude cloud forest. Farther south, in Peru and Bolivia, the high-altitude zone, known as *puna*, broadens into an arid and sparsely vegetated plateau stretching to the horizon. Not surprisingly, paramo and *puna* habitats have little in common with the steaming lowland or the cool montane forests found in other parts of South America. But they also share little with the hot, grassy savannas of Venezuela or the open shrublands of Brazil. The high Andes are more like the Patagonian steppes at the far south of the continent.

The resemblance between habitats of the high Andes and Patagonia applies to the bird fauna as well. An ornithologist familiar with Patagonian birds who was transported 1,500 miles north to the Bolivian high plateau would feel at home. The two areas share a number of genera and several species; even the missing families are the same. How, then, did the high Andean birds evolve? Do they derive from Patagonia or do Patagonian birds derive from the high Andes? How much of the fauna is the result of



David Ewert

Glacially carved valleys intersect at 13,550 feet in the desert paramo of the Venezuelan Andes. At such high altitudes, arborescent espeletias (relatives of the dandelion) dominate the landscape, growing up to eight feet tall in the frost-softened soil.

PLEISTOCENE DISTRIBUTION OF PARAMO AND PUNA IN SOUTH AMERICA

Prior to glacial times, birds colonized the high Andes via several routes. The distributions of these birds altered as the vegetation types fluctuated during the glacial–interglacial cycles. In glacial times (left), paramo and puna *vegetation were more extensive and reached lower altitudes than in interglacial times, such as the present (right). Some new bird species arose as a result of isolation of paramo and* puna.

speciation in the high Andes themselves and how much the result of immigration from lowland areas?

These questions boil down to a classic problem in biogeography; in this case, how to explain the history of about 180 species of birds. The procedure is a bit like detective work: look at the evidence, omit no detail, and reconstruct the circumstances of the crime. The crime was committed in only one way, but the circumstances can almost always be variously reconstructed, depending on the interpretation of certain crucial details. Similarly, although the fauna of a region evolved in only one way, different scientists working with the same biogeographical evidence may well suggest dissimilar reconstructions of that evolution.

We need two kinds of clues: historical ones—ideally, abundant fossil remains—and modern ones, revealed in the distribution patterns of living species. Fossils of high Andean birds

are so scarce that they are virtually useless. Biogeographers are, however, beginning to learn about the history of some Andean environments through the work of palynologists, who study pollen, and about the history of the mountains themselves through the efforts of geologists.

In the Andes today, permanent glaciers are found only at the highest altitudes, but in the past they extended much farther down the mountainsides. In several areas of Venezuela, Colombia, and Peru, moraines and fluvioglacial accumulations of rocks and other materials attest to between one and three major glacial advances. But if the Andes, like parts of Europe and North America, witnessed four major advances, why are they not all recorded? One view is that at the time of the earliest glacial advances in the Northern Hemisphere, the Andes were not sufficiently high to have had glaciers. The high, alpinelike environments of the Andes (the wet paramos of Venezuela, Colombia, and Ecuador and the drier *puna* of Peru, Bolivia, northern Argentina, and northern Chile) probably only date from the mid- to late-Pleistocene era, one to two million years ago.

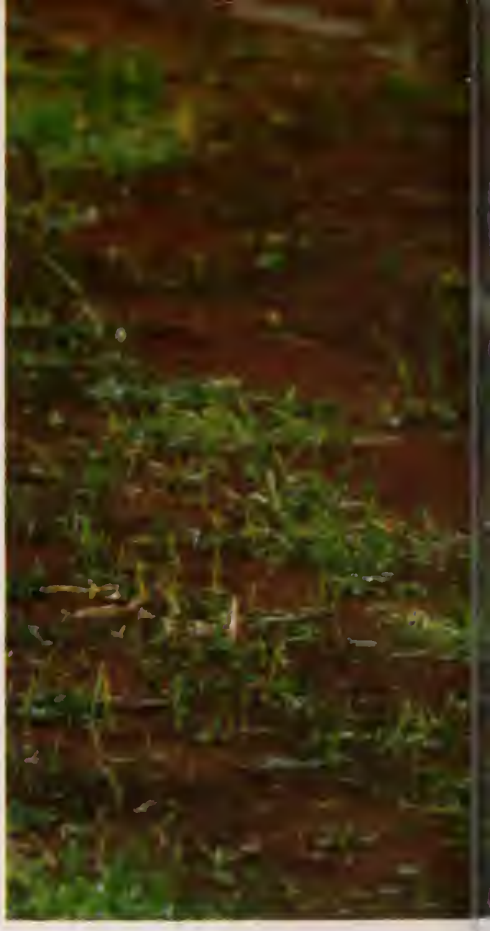
While not definitive, pollen data also suggest that the Andes have been high for a geologically short time. Palynologists have carried out several detailed studies of cores taken from ancient bogs in the Andes of Venezuela, Colombia, and Bolivia. They have dated the peat from different core depths and counted and identified by species the pollen grains found in the peat. The resultant "pollen profiles" indicate how much pollen was contributed by different species of trees or grasses at different times and different places. For example, at one locality in the Colombian Andes, currently at an altitude of 13,500 feet and situated fully within the paramo zone, the vegetation apparently changed repeatedly during the last 15,000 to 20,000 years. At times, woodlands occurred at the site, while in other periods the vegetation resembled the wet grassland that now dominates the area. The overall picture of the Andes is one of vegetation zones that have been alternately lower and higher over about the past 100,000 years. During cold, glacial episodes, alpinelike vegetation reached much lower altitudes than it does now. By contrast, at the peak of warmer, interglacial episodes, the zones moved up, so that the paramo and *puna* region was even more restricted to mountaintops than today.

If a given bird species now found exclusively in alpinelike grassland had the same habitat requirements in the past, its distribution would have changed over time according to the periodic contractions and expansions of its environment. Theoretically, this "cycle" of habitat disruption could have led to the formation of new species, and not surprisingly, different subspecies or, indeed, species of birds do sometimes occur on mountaintops that are now geographically isolated from one another. In other cases, differentiated taxa are found in close geographical contact; careful study of these contact zones has revealed hybridization in some instances and slight range overlaps without hybridization in others.

We have here a model for speciation, and hence faunal buildup, from within the system. The bearded helmetcrest (*Oxypogon guerinii*), for example, is a small hummingbird inhabiting the high altitudes of four isolated Andean regions: three in Colombia (in the Santa Marta Mountains, the eastern Andes, and the central Andes) and one in Venezuela. Because the birds in each of the four allopatric, or geographically isolated, populations are morphologically differentiated, ornithologists once treated them as species; they are now considered subspecies. A possible sequence of events leading to this pattern is not hard to imagine. During a glacial period, a formerly widespread ancestor may have lived all along the central and eastern Andes and extended north into Venezuela and the Santa Marta Mountains. At this time, the paramo zone, in which the ancestral helmetcrest lived, was lower and more continuous than today. As glaciers melted, the paramo zone moved upward and became restricted to small pockets on mountaintops. Today, only the tallest summits, possessing the appropriate type of scrub and woodland, harbor the helmetcrest, whose isolation into four patches might have begun as recently as 20,000 years ago.

Should the climate become colder and glaciers push down the paramo habitats once again, I predict that the four isolates would come in secondary contact as their preferred habitat became continuous or nearly so. If complete speciation has taken place by the time of this secondary contact, geographical overlap might occur, and a region formerly inhabited by one ancestral species could be occupied by two daughter species. Such speciation may be a corollary of fluctuations in the environment that, in turn, resulted from climatic changes during the glacial–interglacial cycles.

Much of the previous reasoning is based on the assumption that a species' habitat requirements are largely invariant in time. This is not, however, necessarily the case. The bar-winged cinclodes (*Cinclodes fuscus*), a brown, dipperlike bird that runs along the ground in search of insects and other small animals, is one of several wide-ranging high Andean birds that have geographically variable requirements. In some parts of the high Andes, this species of cinclodes is found in relatively dense and moist grassland, whereas elsewhere it inhabits much drier and more open scrub. If its habitat requirements vary geographically, there is no reason to believe they did not also vary temporally.



Another complicating factor is that species do not live alone; they share their preferred habitat with other species. To what extent are the habitat preferences of one species modified by the presence (or the absence) of another species, especially an ecologically similar relative? Does interspecific competition somehow rule how many species can live together in the same patch of habitat? While competition between species is an important ecological—and hence also evolutionary—factor, the precise role of competition in determining species ranges and influencing speciation (or extinction) is currently under great debate.

After an extensive analysis involving seventy-nine species of land and freshwater birds endemic, or restricted, to the high Andes (representing about 44 percent of the total avifauna), Daniel Simberloff of Florida State University and I found good evidence that competition had been a causal factor in the distribution pattern for no more than six of the seventy-nine species. For example, in the case of canasteros (small, drab birds of the genus *Asthenes* that look like long-tailed wrens and build dome-shaped, covered nests), the distribution pattern is a mosaic in which several species do seem to replace each other at given study sites, rather than coexist. We concluded that the species of canasteros are mutually exclusive,

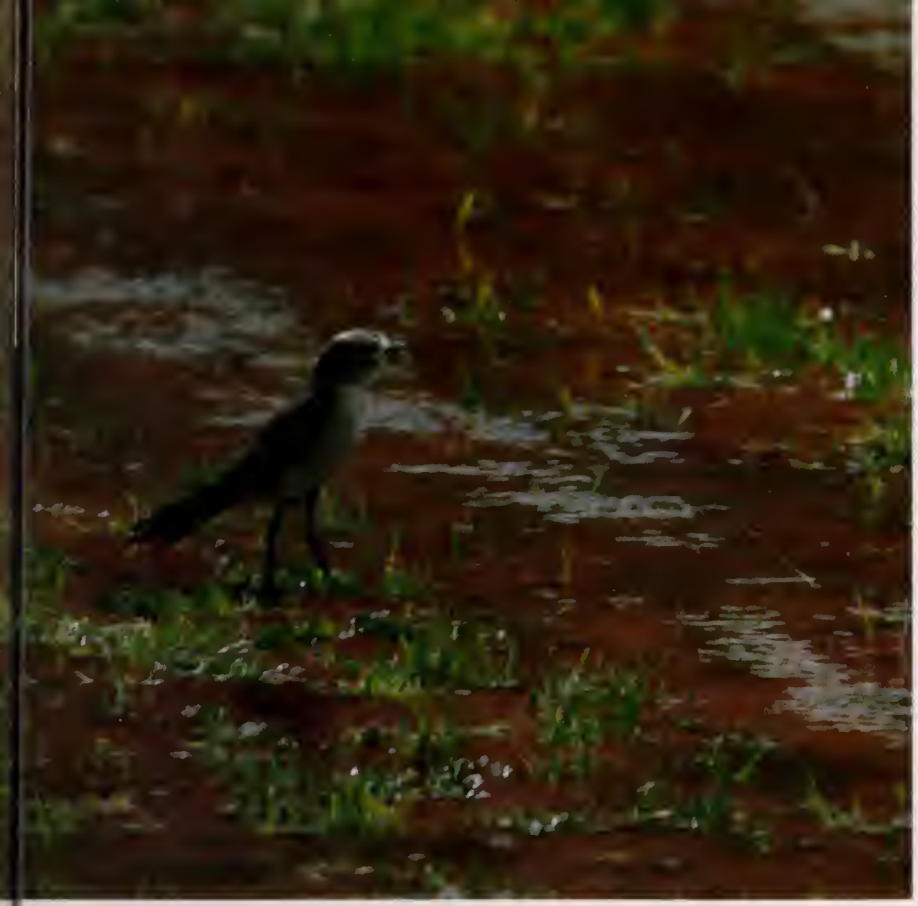
A Greensmith, Ardea London

Peter W Post

Several Andean bird species are widely distributed: the bar-winged cinclodes, above, breeds from Colombia to Patagonia. The distribution of others is more restricted: the ochre-naped ground tyrant, right, breeds in the Patagonian Andes and migrates north to winter in the puna *of Peru.*

a situation likely to result from interspecific competition. But in many other species, the primary causal agent of their Andean distribution may be associated with the glacial cycles. Competitive interactions may occur at all times, but in most cases, the ever changing nature of the external environment would probably prevent interspecific competition from lasting long enough to settle distribution patterns as it has with the canasteros.

So far I have examined some mechanisms that help explain species dynamics in the high Andes once ancestral species occupied the newly opened habitats that formed after the mountains reached great heights. But how old is the fauna, and where did the ancestral stocks come from? A classic way of answering these sorts of questions has been first, to look at levels of endemism—which can provide an indication of the age of the fauna and the relative importance of immigration and local speciation—and then to compare the fauna with others nearby that might have received or contributed species during the time being considered. What do these two aspects of faunal analysis tell us about high Andean birds?



In the high Andes, endemic taxa would be those restricted to above timberline. The problem with this definition is that while some places have a sharp timberline, which effectively delimits two drastically different habitats (for example, cloud forest below, paramo grassland above, as in Colombia), in other areas (including the western slopes of the Peruvian Andes) there is no timberline. In the analysis that Simberloff and I carried out, we defined as endemic a taxon that lived only in the paramo and *puna* types of vegetation. We studied 147 species at forty sites (the total avifauna includes about 180) and found 79 to be endemic. In other words, nearly half the high Andean species are endemic, a rather high percentage.

In contrast, very few genera—4 out of 85—are endemic according to the same definition: a wader (*Phegornis*), two hummingbirds (*Oreotrochilus* and *Oxypogon*), and a finch (*Idiopsar*). Finally, not a single avian family is endemic.

The low level of endemism at the genus level suggests a relatively young fauna. The high percentage of endemism at the species level, however, could indicate a rather old fauna. This apparent contradiction might be resolved if the species endemism is the result of a high rate of recent speciation. This speciation could be either local—that is, occurring only within the high Andes—or the result of immigration followed by differentiation.

In birds, speciation is generally thought to be allopatric, involving the geographical division of a single species into two or more daughter species. Two good examples of local speciation in the high Andes include the white-throated and red-backed sierra finches, *Phrygilus erythronotus* and *P. dorsalis*, which look a little like oversized juncos, and the plain-capped and cinereous ground tyrants (*Muscisaxicola alpina* and *M. cinerea*), slender, long-legged, terrestrial flycatchers. In both cases, the two species replace each other geographically except in a very narrow contact zone. A later stage in speciation is sympatry, when two formerly isolated species live together in the same habitat or share the same distributional range. I consider the plumbeous (*P. unicolor*) and red-backed sierra finches to be such a sympatric pair, as are the cinereous and *puna* (*M. juninensis*) ground tyrants.

To determine how much speciation has occurred *in situ*, we attempted to arrive at an estimate of the number of allopatric and sympatric species among the 147 birds in our study. Allopatric species representing recently completed speciation number about 12 to 20; sympatric species that

may have been the result of local speciation number between 21 and 55. The variability in these figures reflects uncertainties in interpreting the data. A conservative estimate would be that about 20 to 25 percent of high Andean species are the result of local speciation. The rest, the overwhelming majority, therefore appear *not* to be the result of local speciation (unless their speciation is so ancient that it cannot be detected in present-day distribution patterns). This breakdown of species suggests, then, a high influx of immigrants, which in time have become endemic to the high Andes. In either case—local speciation or immigration—the age of the fauna remains largely unknown.

Determining where ancestral stocks came from can be equally complicated. We can compare lists of species living in paramo or *puna* vegetation with species living in other types of Andean vegetation (such as cloud forests and the open woodlands of the intermontane arid basins) or in the Patagonian steppes. This comparison reveals that the high Andes share more species and genera of birds with the Patagonian steppes than with any other ecological unit. This is not surprising since these two habitats are structurally very similar. The Andean *puna* and the Patagonian steppes, for example, share 48 percent of the total species found in them, while only 13 percent are shared by the *puna* and the geographically closer cloud forest. This would appear to vindicate F.M. Chapman's view, first published in 1917, that paramo- and *puna*-dwelling birds originated in southern South America, including Patagonia, and moved northward and altitudinally upward along the Andean corridor, colonizing as far as Venezuela and extreme northern Colombia. But Andean birds may also have contributed to the Patagonian fauna, and there may have been other routes of exchange as well. Birds of the *puna* and birds of the intermontane arid basins of the central Andes are somewhat related faunally; these regions share up to 30 percent of the species living in them, so that some exchange appears possible. Several high Andean genera and some species also occur in North America, which suggests another possible avenue of faunal flow. Examples among the species include the marsh hawk, the great horned owl, and the eastern meadowlark; among the genera, the stiff-tailed ducks, avocets, and flickers.

What can one conclude? Reconstructing the avifaunal history is clearly not easy. Readers interested in cautious scientific interpretations can turn to my technical papers; here let me indulge in speculation on a few of the birds found in the high Andes.

Once upon a time in the late Tertiary, about two to three million years ago, the Andes were not very tall mountains. In what is now Colombia and Ecuador to the north, their tops were either clad with cloud forest or, on the highest summits, covered with scrub. The high-altitude avifauna there included flycatchers, hummingbirds, tanagers, cotingas, and antbirds. Farther south, in Bolivia, plateaus were covered with savannas and woodlands, where caracaras, finches, and blackbirds lived.

As orogeny proceeded and the mountains increased in altitude, local timberlines developed, and above them appeared a cold, treeless habitat dominated by grasslands and moorlands. The formation of this habitat, the precursor of today's paramo and *puna*, was the turning point in the faunal history of the high Andes. At first, few birds other than wide-ranging species that normally inhabit open spaces—ducks, coots, ibises, and waders in moist areas and lagoons, hawks in dry places and cliffs—could live in these habitats.

Some of these birds are good fliers and could have come from almost anywhere: from lower down the mountainsides, provided the slopes were not forested; from southern South America; and even from North America. Today's paramo and *puna* are inhabited both by relicts of these early colonizations and by wide-ranging species that have invaded the high Andes more recently. Single stray birds from the lowlands, such as the wattled jacana (*Jacana jacana*) I saw at 10,000 feet in northwestern Argentina, are unlikely candidates for colonization. But many birds travel in flocks and can thus potentially stay and breed in areas far from their normal range.

Seed-eating finches and doves invaded the high Andes above timberline soon after seed-rich grassland habitats opened up. Little adaptive modification was required of these birds. Siskins—finches whose flocking behavior and wandering tendencies make them excellent colonists—could have come from almost anywhere. Since they eat buds and other veg-

etable matter as well as seeds, they might easily have shifted from a forest to a shrub environment. In the *puna*, the endemic thick-billed siskin (*Spinus crassirostris*) appears to be restricted to some very high altitude woodlands found within the grassland and scrub and may have derived from the smaller-billed hooded siskin (*S. magellanicus*), a species with a wide range and broad habitat tolerance. The buntings, which include the yellow-finches, may have moved in from open areas farther south, perhaps the grassy pampas or the Patagonian steppes, rather than the forested slopes below the newly formed paramo and *puna* zones. The arid woodlands of the montane basin, however, are almost as likely an original habitat for these stout-billed finches. As for the doves, they probably came from lower altitudes, and originally perhaps from North and Central America.

What about the small, brown ground-dwelling miners, other members of the diverse family Furnariidae, and the ground tyrants of the genus *Muscisaxicola*? These birds subsist on a diet that consists primarily of insects. Since none of the high Andean furnariids appear related to Central American stocks, they would seem to have come from farther south or southeast in South America, either the campos (grasslands) of Brazil, the pampas, or the Patagonian steppes. But they could also, in part, have evolved locally in the central Andes, from stocks living in cloud forests down the slopes. The landscape probably progressed slowly enough from savanna or woodland to arid grassland or shrubland for such an ecological and evolutionary transition to be possible.

The *Muscisaxicola* ground tyrants are an extraordinary group of birds with unusual habits—for flycatchers. They live away from trees and hop and run along the ground on their long, thin legs. The proto-*Muscisaxicola*, having "discovered" the ground niche, then diversified into a large number of species by allopatric speciation, a good example of adaptive radiation. Several of the species are exclusively high Andean. Did they originally come from stocks already living in open spaces elsewhere, such as Patagonia? Perhaps, but not necessarily. While eight or so species of ground tyrants do live in open habitats along the Andean axis, from mountaintops in Colombia to southernmost South America, one species lives along rivers at the forested base of the Andes. The possibility thus exists that the ground tyrants evolved from lowland ancestors living in openings in forested habitats. The ecological preferences of the closely related chat tyrants (genus *Ochthoeca*) may shed light on the origin of the high Andean ground tyrants. Chat tyrants encompass all ecological intermediates, from cloud-forest species to arid-scrub species living high up in the *puna*, without much morphological or behavioral change. One species, the brown-backed chat tyrant (*Ochthoeca fumicolor*), even shows intraspecific variation in habitat preferences: in the Venezuelan Andes, for instance, I have observed these birds in dense montane woodlands at about 11,000 feet and in increasingly more open habitats all the way up to 14,500 feet in desert paramo.

If the chat tyrants have invaded the geologically young paramo and *puna* habitats from lower-altitude

The twenty-foot-tall puyas (relatives of the pineapple) growing at 13,000 feet in Peru, below, and the yellow-finch resting on a cushion plant in Bolivia, right, are characteristic of puna *landscapes.*

NATURAL HISTORY

A Gandharan frieze of gray schist from about the fourth century A.D. The toga worn by the Buddha, center, indicates the Greco-Roman influence on Indian art. The frieze measures about 10 x 15 x 2½ inches. Gift from the Lester Wolfe Collection. Photograph by Arthur Singer, AMNH.

montane forests, their distribution pattern may represent an earlier stage in the origin of ground tyrants. When it inhabited montane forests, the proto-*Muscisaxicola* of the high Andes might have looked and behaved like a chat tyrant, and then become modified during further evolution in the treeless *puna* and paramos. Eventually only the high-altitude species survived.

Figuring out what direction the shift in habitat preference took, however, is not as straightforward as it might seem. At face value, if there are currently more species in one habitat (*puna* or paramo) than the other (montane forest), the shift would appear to be from *puna* or paramo to forest. But speciation and extinction cycles, mediated by the external environment and modified by competition, could have turned things around so that today's lowland, forest-dwelling little ground tyrant could be either an ecological relict of the early forest history of the genus or a recent colonist from high-altitude, open habitats. Because it is almost as highly modified morphologically as the ground tyrants of high altitudes (or high latitudes, in Patagonia), I propose that the little ground tyrant is more likely to be a recent colonist.

This rough sketch gives an idea of the many different ways in which the birds of the high Andes may have evolved. Some species originated right there from ancestors that lived in more forested environments when the mountaintops were not so high; some are relative newcomers whose ancestors came from North America, from southern South America, or from the dry lowlands at the base of the Andes. Complicating the picture, some species are little different in morphology and behavior from closely related birds found elsewhere, while others have had a longer, more complex history. Challenged to reconstruct this history from often woefully inadequate evidence—involving shifts in habitat preference that trail far back in time, speciation between isolated mountaintops, and morphological and behavioral adaptations to the high Andes—the biogeographer may occasionally have cause to envy detective Hercule Poirot. □

Winners of the 1981 Natural History Photographic Competition

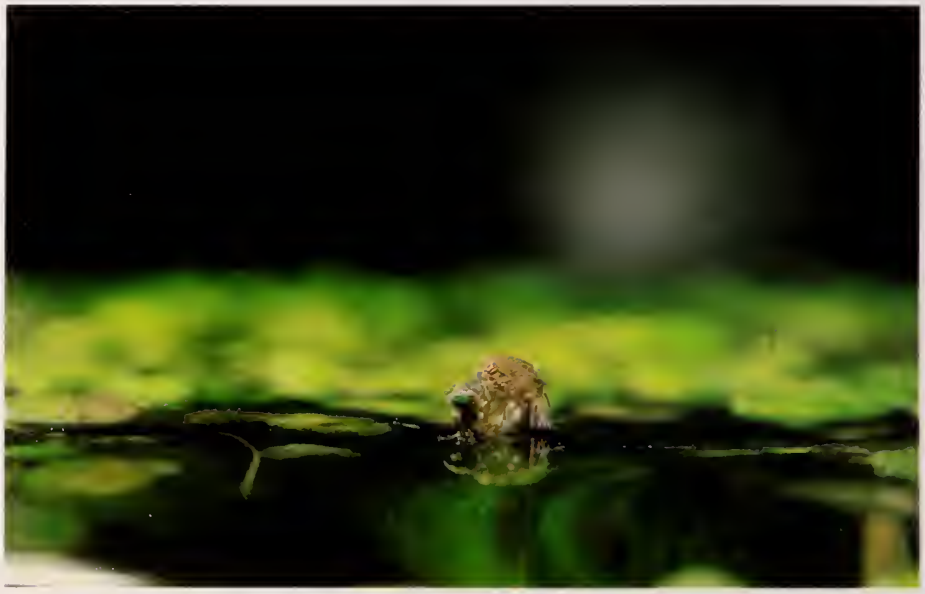
Participation in this year's Photographic Competition was enthusiastic, and many contestants were attracted by the announcement of a new category, Historical Photographs. With each entrant allowed to submit up to five pictures, thousands of photographs arrived at our offices for examination. The task of the three judges was to view approximately 400 slides and prints chosen as finalists by *Natural History*'s designer and picture editor. Presiding this year were David Doubilet, an award-winning photographer for the National Geographic Society, who specializes in underwater work; Ken Heyman, a photographer widely recognized for his interpretation of the human condition, who collaborated with Margaret Mead on numerous projects, including the books *Family* and *World Enough*; and Mary Ellen Mark, a noted free-lance photographer whose credits include the books *Passport*, *Ward 81*, and *Falkland Road*.

In handing out the various prizes, the judges deviated in one respect from the announced provisions of the competition. In one of the major categories, Plants and Their Environment, they were faced with a black-and-white photograph and color photograph that they admired equally, and so declared a tie for first place. First Prizes were bestowed without such indecision in the other two major categories: Animals and The Human Family. Additional photographs earned Merit Awards in Photomicrography, A Sequence in Nature, Historical Photographs, and Humor in Nature, while nine entries received Honorable Mention. Finally—with some apologies for their unconventional choice—the judges awarded the Grand Prize to the one photograph that most impressed them.

Our thanks to all who took part in this year's contest. The deadline and rules for the 1982 competition will be announced in a future issue of *Natural History*.

Vittorio Maestro

FIRST PRIZE
The Human Family
NANCY L. WEINBAUM
A cousin cheerfully helped out by holding up the subject when Nancy L. Weinbaum photographed her six-month-old niece back in 1976. Weinbaum, a high school teacher who lives in Trenton, Florida, teaches art classes and is adviser for her school's yearbook and newspaper.



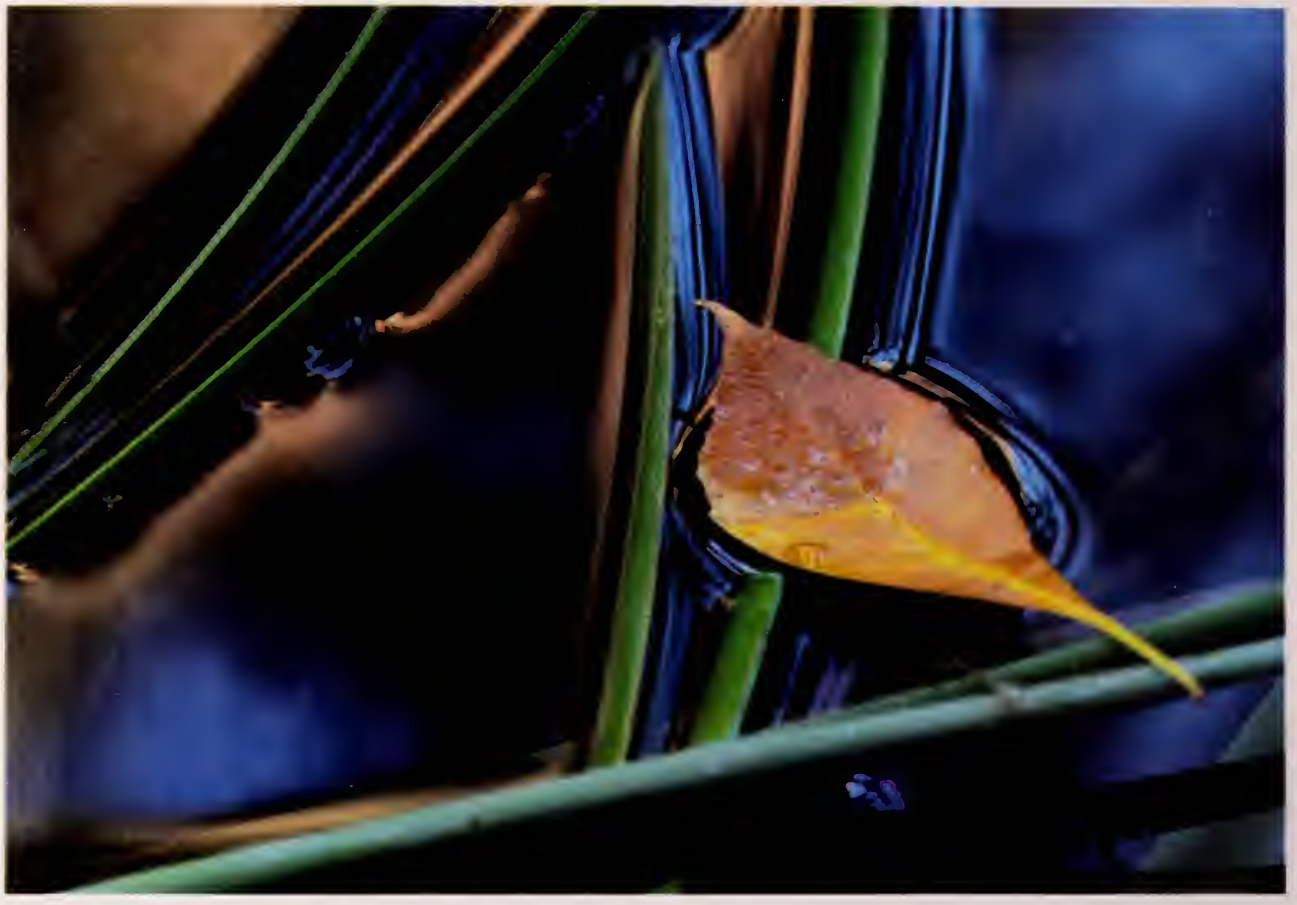
FIRST PRIZE
Animals
TOWNSEND WEEKS

A grant from the College of Marine Studies at the University of Delaware enabled marine biologist Townsend Weeks and a colleague to spend the summer of 1977 taking photographs at Cape Henlopen, on the Delaware coast. While in Canary Creek Marsh, Weeks noticed a spider moving rapidly on an Iva *plant and managed to take two pictures, this one with the flash held slightly behind the leaf. Seconds later, the spider was gone. Weeks now lives in Northvale, New Jersey, and teaches general and field ecology at Ramapo College.*

FIRST PRIZE (Tied)
Plants and Their Environment
KEITH AXELSON

Five years ago, Keith Axelson was spending his weekends at a ranch in San Luis Obispo County, California, studying the nesting behavior of golden eagles. One hazy spring day, when an eagle landed down below him, Axelson's attention was drawn to a mule deer, and he managed to grab a camera from his blind in time to snap its picture. A California live oak dominates the landscape. Axelson, a free-lance graphic designer and photographer, lives in Los Angeles.

MERIT AWARD
A Sequence in Nature
G. I. Bernard



In a marsh environment set up in the laboratories of Oxford Scientific Films in England, a common female mosquito emerges from the pupal stage beneath the water. Air taken on by the mobile pupa makes it buoyant enough to break the water's surface and enables the adult flying machine to separate from its aquatic shell. G. I. Bernard, a professional still photographer on the staff of Oxford Scientific Films, captured the four- or five-minute sequence using a camera fitted with an old microscope lens.

FIRST PRIZE (Tied)
Plants and Their Environment
BETTY RANDALL

A box elder leaflet lies among cattail stems in a bog in Utah's Zion National Park. The photograph, taken in the shadows of a canyon that is about 2,000 feet deep, captures reflected, rather than direct, sunlight. Betty Randall is a free-lance photographer who lives in Coarsegold, California.

MERIT AWARD
Photomicrography
SUZANNE GROET

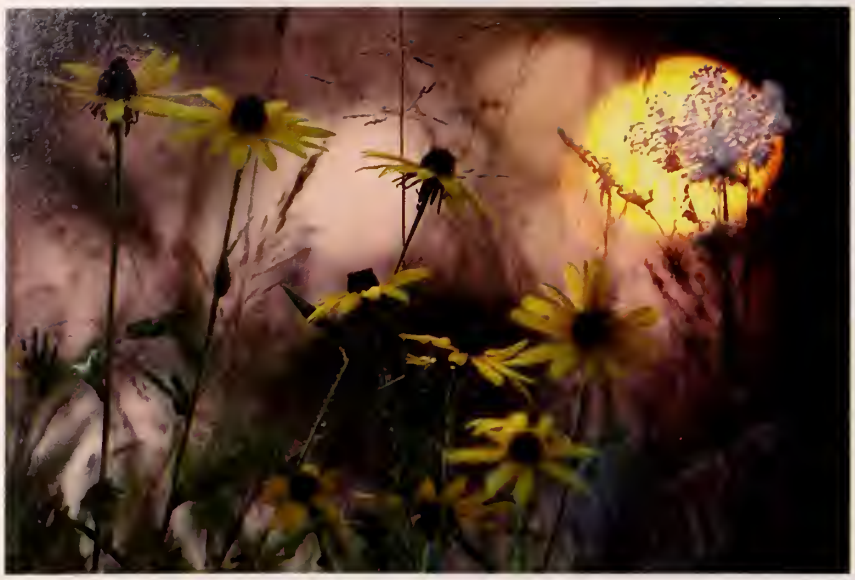
Resorcinol is a chemical used in manufacturing resins, dyes and other products, and in veterinary medicine as a topical antiseptic. In the form of a "melt crystal," created when a crystal melts and recrystallizes on a slide, resorcinol displays artistic qualities as well. The photomicrograph was made with polarized light, using a Zeiss microscope to provide X32 magnification; the color was modified by a retardation filter. Suzanne Groet, a botanist living in Upper Arlington, Ohio, began taking photomicrographs four years ago.

GRAND PRIZE
LEE D. FILERMAN

Although he lives in New York City, Lee D. Filerman found out that in 1980, the best place to photograph the Statue of Liberty was Lake Mendota, Madison, Wisconsin. It seems that when the flamboyant Pail and Shovel Party seized control of the student government at the University of Wisconsin, they lost no time fulfilling their campaign promise to bring the Statue of Liberty to Madison. At a cost of $4,000, the students erected a styrofoam, metal, and wood structure to represent the statue, which, they claimed, had sunk through the ice. The Pail and Shovel Party sculpture has since been disassembled, while the party itself, having left the student government in debt, keeps a low profile. Filerman, a work force administrator and grant writer, has no professional training in photography, although he has been at it for many years.

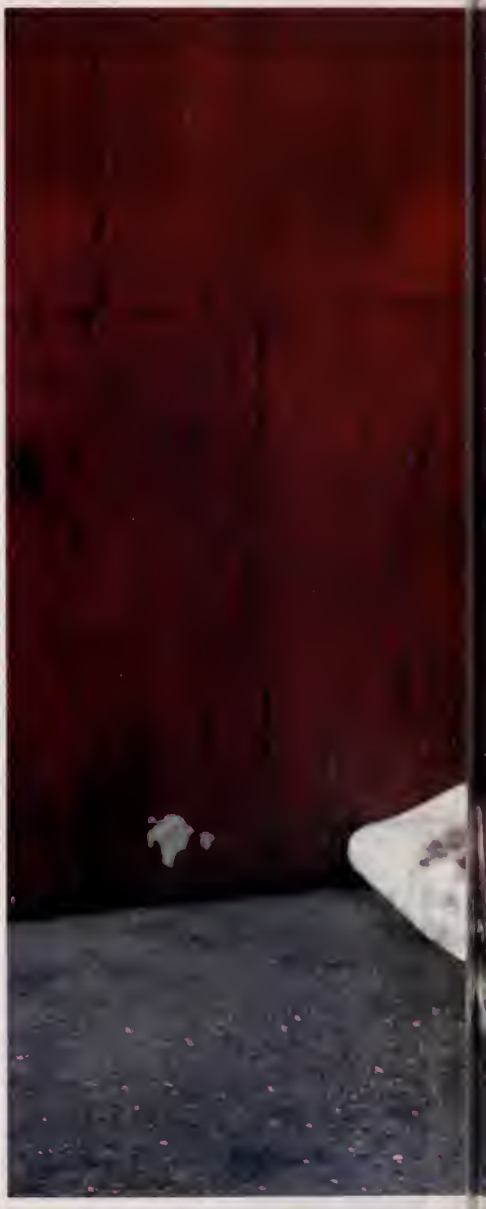
MERIT AWARD
Humor in Nature
DAVID RUSSELL MILLER

While visiting a hospital treatment center one day, David Russell Miller began taking photographs of a man at work in his garden next door. After a few minutes, the man stopped working and slowly climbed the stairs. He was not aware of the photographer until he turned and sat down, whereupon he smiled and doffed his hat. Miller, a chemical engineer who lives in Oakland, California, titled his work "Ascent of Man."



HONORABLE MENTION
Plants and Their Environment
RUTH FREEDMAN

Ruth Freedman likes to experiment with close-ups of flowers, leaves, and other natural forms. Here, the inner sections of a bell pepper are aglow with transmitted light. Freedman, a housewife in Stockton, California, has long enjoyed photography as a hobby.



HONORABLE MENTION
Plants and Their Environment
ERIC ALBRECHT

The rays of the sun, setting over a hill near Magnolia, Ohio, filter through black-eyed Susans and Queen Anne's lace. Eric Albrecht is a newspaper photographer in New Philadelphia, Ohio.

HONORABLE MENTION
Animals
J. R. SCHNELZER

J. R. Schnelzer, a teacher and naturalist living in Westerville, Ohio, raises cecropia moths to photograph their life cycle. This one was attracted to a columbine in Schnelzer's wildflower garden.

HONORABLE MENTION
The Human Family
F. B. GRUNZWEIG

Long-time professional photographer F. B. Grunzweig has a special interest in the homeless people who live in his native New York City. This photograph of a human scene, which in Grunzweig's view expresses defeat, was taken behind the city's main bus terminal on a Sunday afternoon in the summertime.

MERIT AWARD
Historical Photographs
CARY HULL

This scene in the redwood region of northern California is reproduced from a glass-plate negative exposed about 1905 by a professional photographer, Jesse A. Meiser. Meiser, who died in 1939, had his primary studio in Eureka, California. The photograph was entered in our competition by Cary Hull, who printed a collection of Meiser's glass plates and has reproduction rights to the prints. In addition to doing free-lance photographic work, Hull is a conservationist with the Soil Conservation Service. He lives in Albuquerque, New Mexico.

HONORABLE MENTION
Animals
RICHARD SCHOER

While in the Monte Verde Cloud Forest Reserve in Costa Rica, Richard Schoer wanted to photograph Bufo periglenes, *the secretive "golden toad." Ranger "Wolf" Guindon advised him that the best time to find members of this species was in the middle of the night, during their mating season. These are males that have come to a water hole to await the appearance of females. Schoer, a resident of New York City, works as a free-lance photographer and sculptor's assistant.*

The original, indispensable KLUGE® BAG

The "No-Waiter"

A six piece set in one easy to carry-on ...for overnight or around the world.

Two time TV Emmy Award Winner Stan Hart: "The Kluge Bag is the best. The only piece of luggage I ever use."

Pennsylvania cattleman Robert Johnson: "For quality, convenience, organization, the Kluge Bag tops any set of luggage I've ever used."

Kingport, Ltd. President Ed Gerch: "One carry-on piece sure beats three or four check-in bags. I'm delighted."

Here's the famous original you'll see on the Concorde, the Air-Shuttle to Washington, the commuter out of O'Hare. The Kluge® Bag. The only combination overnighter and fortnighter in the world.

And the only bag that's as easy to carry to the last airline gate with a complete wardrobe as it is with a single change of clothing.

A "no waiter" you never check in. Never have to wait for at the baggage counter.

Extra Comfort and Convenience

You'll use the Kluge Bag like a week-ender, too, because it's just as easy to carry on and a whole lot better. Better because nothing gets wrinkled or creased... because you have extra room for all the reports and papers you need, the tennis things you may or may not use, the sweater you'd like to be able to knock around in at night, and to bring back anything from reports to a new suit you pick up on your trip. (You can prove it yourself at our risk!)

Beautifully Organized

The almost infinite flexibility is the result of an organization system designed by Peter Kluge, an international businessman, who travels constantly, from Chicago to Dallas, New York, Los Angeles, to Europe and the Middle East, never sure if he'll be away two days or two weeks, or of the clothing he'll need.

So, in one lightweight, compact, easy-to-carry handle or shoulder bag you get (1) a garment bag that holds two suits, (2) a pullman case, (3) a week-ender, (4) a tote-tennis bag, (5) a toilet-accessories kit, (6) a laundry-wet stuff bag...plus a full-size portfolio. Compartmentalized for easy access to your shirts, ties and belts; shoes and socks; underwear; suits, slacks and jackets; sportswear, sweater, bathrobe; business reports and papers. Anything and everything you need.

One Vs. Two, Three or Four

You can't even begin to compare the ease and convenience of the Kluge (rhymes with huge) Bag with the bulky, heavy, loaded-down check-in luggage you usually carry on trips of three, four or more days.

The Kluge Bag alone easily outcarries a garment bag, a weekender or pullman plus a dispatch case. It not only looks better, weighs less, it's also much easier to carry and leaves your hands free to get your wallet or ticket. The Kluge Bag comes with a specially designed hook which allows you to hang it in the garment compartment of the plane. Most important of all, only the Kluge Bag is always ready when you are to get off the plane.

Top Quality Construction

Simply, there's no other piece of luggage anything like this. Beautifully made of top-quality rayon, the material that's most often used in expensive luggage today because it's as strong as it is light, and will retain its beauty through years of use and abuse, the Kluge Bag is available in natural canvas color with rich brown piping and in striking solid black diamond and brown trim.

Outside there are three sectional zippers, so you can get to anything in a second, with a security snap lock and a valet snap lock safety strap, plus comfortable carrying handles and the adjustable burden-bearing shoulder strap.

Inside, a fold-up rigid bottom supports everything you can carry in the zippered main compartment. The fittings and details are equally impressive, like a tie rack, a fitted compartment for toiletries, a zippered compartment for valuables, pockets for cards, notes, keys and more. Plus a huge volume portfolio. Everything you need to make packing and traveling for days or weeks easier and faster than it's ever been before. Yet fully packed the Kluge Bag is just 19" high by 22" wide and 8" deep.

Only $49.95!

Most extraordinary of all, though, is the price. At $90 and $100, which is the price you'd have to pay for a bag like this in a fine retail store, the Kluge Bag would be an excellent value. At **$49.95** plus $4.95 shipping and handling, it's absolutely unbeatable.

A price that's possible because we're able to commit for an entire manufacturing run, and to eliminate salesmen, distributors and retailers and their costs by selling direct.

No Risk Trial

Now we invite you to try the Kluge Bag for yourself — for 30 days without risk or obligation. Don't worry about how you handle it. Nothing will hurt it. You must be convinced that it's the finest, most useful, convenient and versatile piece of luggage on the market today, a time and trouble saver, the perfect piece for every trip, or return it for a complete refund. No questions asked.

CALL 800-228-5959

Nebraska residents call 800-642-8777
(In operation 24 hours, 7 days a week)

The Kluge Bag is also available with rich belting leather trim. The price is just **$79.95** plus $4.95 shipping and handling.

NEW! As a result of thousands of calls, an all leather Kluge Bag is finally available. Made of the finest, softest, most durable dark brown leather, it can only be used with pride. Only $250.00 plus $4.95 shipping and handling. When ordering, please specify, the *ALL LEATHER* Kluge Bag.

To order with any major credit card, just call us at the toll free number above. Or send your check to Dimensions Unlimited, Inc. at the address below. (Illinois residents please add 6% sales tax.) Be sure to specify natural or black with vinyl or leather trim, or the new *ALL LEATHER*. Take the lug out of luggage, the wait out of baggage.

E. Leitz, Inc., Rockleigh, N.J. 07647.

You wouldn't hang a Picasso in the closet. You'd show it in its best light. Proudly. Leica feels the same way about photography. It would be a pity if pictures taken with our amazing R4 weren't projected with our equally amazing Pradolux* RT300. Each is superb. Together, incomparable.

Consider the Leica* R4, the camera that's so automatic, so responsive, it can do everything, simply. It's the only camera in the world with two independent light meter systems. You can select either full-area (averaging) or selective (spot) metering with a touch of the controls. And you have multi-mode exposure automation working with the two metering systems. Again truly unique. This gives you shutter priority, aperture priority, programmed control, metered manual and flash automation in fractions of a second. And you have a full system of accessories including motor drives and the incomparable Leica-R lenses to bring all this potential to actuality, simply.

The only slide projector made to this high standard is our own: the Pradolux RT300. It offers Leica lenses in a full range from 60 to 200mm in both curved and flat-field configurations. The internal condensers are just as important as the lenses. That's why ours are Leica optical quality, too. You can count on high efficiency cooling for long life of the projector, the lamp and your slides. The Pradolux RT300 accepts Kodak Carousel* trays and stack loaders. Plus a range of built-in features that seems to go on forever.

*TM Eastman Kodak Company.

In fact, with both the Leica R4 camera and Pradolux RT300 slide projector you will see how impressive your images really are, Pablo. Ask your full-line Leica dealer for information; he's listed in the adjacent column.

BARRON HALEY

The Agave americana*'s "sensuous" spines made Barron Haley's entry a close contender for the Humor in Nature award. Haley, a junior college instructor in biology and botany, lives in Los Gatos, California. Although photography is just a hobby, he is able to illustrate most of his lectures with slides he has taken himself. His first involvement in photography was a lab course in photomicrography that he took sixteen years ago.*

Nomads' Best Friend

by Valerius Geist

THE CAMEL, by Hilde Gauthier-Pilters and Anne Innis Dagg. *The University of Chicago Press, $26.00; 224 pp., illus.*

Hilde Gauthier-Pilters

This is an excellent book, which I recommend if only for sheer reading pleasure. The book details—without generating boredom—the life of the camel, a remarkable creature that inhabits, along with nomad herders, some of the world's most inhospitable landscapes. The authors give a vivid introduction to the ecology of the Sahara and to the life of the animal that makes it possible for humans to exploit the hot desert. Camels and nomads live in a bond of mutual dependence: the camel needs nomads to give it water from wells in summer, and nomads need camels to provide milk, wool, transportation, and meat, and above all, to provide work and give meaning to their lives. To live by the camel requires attributes that are highly valued by all people, regardless of the society. Yet, the shadow of civilization—if one can call it such—has descended on these hardy, independent people and their way of life, as well as on their camels. If humans abandon the nomadic life, the fate of the camel will be sealed, for without humans and their wells, the camel could not live where it now is common. This is a somewhat simplistic overview, but no review could capture the detailed knowledge revealed in the pages of this book.

The work of Hilde Gauthier-Pilters has formerly been accessible only to those literate in German and French. She has written several popular books on her work, delightful accounts that minimize the very real dangers and hardships she endured as a woman scientist alone in the Sahara. In English there is only one paper, a turgid but clear account of her understanding of the ecology of camel and nomad in the Sahara. This paper, presented a decade ago at a symposium on ungulate behavior, is a classic. She had earlier studied captive New World camelids, but soon shifted to studying the ecology of dromedaries and nomads in North Africa.

Anne Innis Dagg made her name by studying giraffes and, later, the gaits of ungulates. After writing two books on wildlife management in Canada, Dagg teamed up with Gauthier-Pilters for several study trips into the Sahara. *The Camel* is the fruit of their collaboration, although it is based largely on the work of Gauthier-Pilters, who also wrote most of the chapters and supplied all the photographs. The book's first aim is to give an account of camel autecology; the second, to describe the interdependence of nomads and camels; and the third, to compile a bibliography on camel biology. The result is a most readable, informative, well-illustrated book with two appendixes and a useful bibliography. The work is divided into two parts: one deals with camels; the other with the people who depend on them.

The first part—short on theory and long on observations—is a reasonably broad, but condensed, account of what we know of camel biology. This section is well thought out and devoid of the superficialities so infuriatingly common to the "six month wonders" whose field studies too often grace our scientific journals. This book is solid stuff! Authoritatively written with plenty of hard work to back each of its sentences, the book is also an example of how the nomad's traditional knowledge of camels can be used to good advantage without losing scientific objectivity. Nowhere is there a better account and explanation of the camel's peculiarities than here.

This hard, scientific account makes it very plain why the camel, in the past, in the present, and almost certainly in the future, will be the only means by which humans can exploit the desert. Without camels the scarce desert resources are almost completely beyond human utilization, just as the tundra would be without caribou, or reindeer, as well as migratory birds and anadromous, migratory fishes. Conventional agriculture is possible on only a tiny fraction of hot desert ranges. Camel herding with its concomitant nomadism is one feasible means of survival. The practice of camel herding, however, requires free-roaming over vast areas in order to exploit rains and fresh vegetation; it cannot tolerate borders. It also requires that Occidental cultures abandon their holier-than-thou attitude toward nomads: the belief that our way

OUR NEW CAMERA VS. NOTHING ELSE.

You might say the new Minolta XG-M is in a class by itself.

Because no other 35mm SLR in its class has its combination of creative features, yet is so easy to use.

All you do is point, focus and shoot.

The automatic XG-M does everything else to give you clear, sharp, beautiful pictures. It even has electronic features to prevent mistakes. And advanced features like manual metering for advanced photographers.

To make things tougher on the competition, we gave the XG-M something you only find on more expensive cameras. The option of professional motor drive, to let you take pictures at an astonishing 3.5 frames per second.

So you can capture fast action. Like a diver's twisting entry into the water. Or a racer's moment of triumph at the finish line.

And when you hold this camera you'll know it's extraordinary, inside and out. Its built-in textured grip was sculptured to fit your hand more comfortably.

And its advanced design represents an exciting new achievement in making fine cameras. Something we've been doing for over 50 years.

The XG-M accepts over 45 interchangeable, computer-designed Minolta lenses. As well as the Minolta system of SLR accessories.

The new Minolta XG-M There's simply nothing else like it.

WAIT 'TIL YOU SEE HOW GOOD YOU CAN BE.

WE GO WHERE THE WONDER IS.

Out to sea, a world is waiting. The cave of Robinson Crusoe on the island of Tobago. A spectacular drive-in volcano on St. Lucia. A charming fishing village at Iles des Saintes where the children sell a cake called Love's Torment (coconut & guava). A 180 mile journey up the Orinoco River to a jungle paradise at Canaima (and a chance to see Angel Falls, the tallest waterfall in the world). It's just part of what happens aboard the Stella Oceanis as she makes one in a series of 14-day Leeward to the Orinoco Cruises out of San Juan this winter. Join us on our yachtlike itinerary. For details, see your travel agent or send this ad for our brochure or call us collect at (212) 397-6400.

Hilde Gauthier-Pilters

of life is so superior we must convert all to it!

This book makes a plea of the same kind made in the *Ugly American*—that real help via technologies from the Occident does not lie in resource projects, resettlements, and jobs that destroy the fabric of the nomad's society, but in simple improvements that make life a little easier and richer. Gauthier-Pilters shows how simple, cheap improvements to existing wells would not only insure a better supply of clean water—the only kind camels will drink—but above all, could get watering done more quickly and thus save pastures in the vicinity of wells from depletion. Her knowledgeable treatment of the problems of grazing and watering in the Sahara are recommended reading for anyone interested in the problems of the Sahel.

This is an important book written by two eminently competent scientists after long studies and with due social and historical perspective. I cannot overstate that. Whether such a book could be written thirty years hence is doubtful; native cultures are rapidly collapsing, impoverishing all of us. In view of the book's significance, my minor disagreements and critiques would be quibbles. I recommend this book; please read it.

Valerius Geist is professor of environmental science on the Faculty of Environmental Design at the University of Calgary in Canada.

AMERICA IS FOR SALE

The United States Map Company wishes to inform you that the whole country can be bought: We are offering you a huge mural map of the United States measuring *NINE HUNDRED AND TWENTY-FIVE SQUARE INCHES*, with leading cities, lakes, rivers, mountain ranges, national parks, forests and historic sites in breathtaking color, *FOR ONLY $1!*

That's right, the entire country is yours for just a buck—a solitary simoleon, greenback, smacker, bof-fo, bean, eight-bit, frogskin, lettuce leaf, shinplaster.

This magnificent mural map is a real eye-popper, ideal for an office, reception area, classroom, den, or child's room.

But there is a limit: only three maps to a customer.

To get your breathtaking Mural Map of the United States, just fill out the coupon below and mail it with payment to the address shown in the coupon.

We deliver this huge map right to your doorstep. You'll have the whole country right at your feet!

Celestial Events

by Thomas D. Nicholson

The Moon New moon occurs at the beginning and end of July (on the 1st and the 30th). First-quarter moon (rising about noon and setting about midnight) is on July 8, full moon (rising at sunset and setting at sunrise) is on July 16, and last-quarter (rising about midnight and setting about noon) is on July 24. In August, first-quarter moon is on the 7th and full moon on the 15th. The moon is at apogee (farthest from the earth) on July 11 and August 8, at perigee (nearest the earth) on July 27 and August 21.

Two eclipses occur in July, both visible in some parts of North America. A partial lunar eclipse on July 16–17 is visible throughout the United States and Canada (except for northern areas), and a partial solar eclipse occurs over Hawaii, Alaska, and western Canada on July 30.

Stars and Planets Venus will be low in the west-northwest about half an hour after sunset, when its brightness overcomes the darkening twilight. Well to the left of Venus, Jupiter and Saturn continue to put on a good show high in the southwest at dusk. Jupiter is brighter than any star in the sky. Saturn is very close and just above it. The two planets have been near one another since last autumn, their retrograde motions keeping them from separating very far. Now both are moving easterly, and Jupiter, the faster of the two, passes Saturn on July 27 and separates steadily to Saturn's left. In the morning, Mercury goes through a poor elongation in July. Mars rises about two hours before the sun in Taurus, near the Hyades and Aldebaran. The sun in July moves from the stars of Gemini into Cancer.

July 3: Mercury resumes its normal (easterly) motion. Earth is at aphelion, farthest from the sun, about 152,103,500 kilometers (94,513,000 miles) distant.

July 7: The very bright planet Jupiter is to the moon's right this evening, and Saturn is just above Jupiter. Spica, in Virgo, is to the left.

July 12–13: The moon can introduce Antares, the bright red star below it.

July 15: The bright gibbous moon will locate Sagittarius for you tonight.

July 16–17: Tonight's partial lunar eclipse begins at 10:24 P.M., EST, mid-eclipse occurs at 11:47 P.M., EST, and the eclipse ends at 1:09 A.M., EST, on the 17th. Adjust for different time zones and for daylight time.

July 28: The Delta Aquarid meteor shower reaches maximum. Up to 20 meteors per hour can be seen for two or three days before and after the 28th.

July 30: Jupiter passes Saturn (conjunction), moving from right to left. This is the third and last event in the "triple conjunction" that began last January.

August 3–4: The moon passes Jupiter and Saturn on the morning of the 4th, moving from their west (right) on the 3rd to their east on the 4th.

August 10th: Mercury is in superior conjunction, in line with but beyond the sun. It now enters the evening sky.

August 12: The Perseid meteor shower reaches maximum early this morning. This is the most reliable and productive meteor shower of the year.

The summer Star Map shows the sky from the mid-latitudes (40°N) of the Northern Hemisphere during the evening hours, at the times indicated below. To use the map, hold it in front of you vertically (facing you) with the compass direction you are facing at the bottom of the map. Thus when you face north, hold the map with north (N) at the bottom, and match the *lower* half of the map with the stars you face on the sky.

During the night the stars in the sky move continuously toward the west. By morning (before dawn) all the stars on the *western* half of the map will have set, the stars on the *eastern* half will have moved over to the *western* sky, and new stars (those of the *winter* evening) will have risen into the east. The map represents the sky at about 2:00 A.M. on July 1; 1:00 A.M. on July 15; 12:00 A.M. on July 31; 11:00 P.M. on August 15; 10:00 P.M. on August 31; 9:00 P.M. on September 15; and 8:00 P.M. on September 30. Add one hour for daylight time. The map can be used an hour or so before and after the times given.

Editor's Note: Beginning this month, the Celestial Events Sky Map returns on a different schedule, supplemented at times by other illustrations of interest. Sky Maps in July, October, January, and April will show the evening constellations and stars associated with summer, autumn, winter, and spring. The precise time for using the maps changes during the season, as the above times indicate, but the principal stars and groups can be found from the maps at any evening hour throughout the season. Other kinds of maps, sketches, and photographs during intervening months will call attention to special areas and events.

The Once and Future Museum

The American Museum of Natural History is a tangled complex of twenty-two interconnected buildings stretching from 77th to 81st Street on the Upper West Side of Manhattan. According to the *Guinness Book of World Records*, it is the largest museum of any kind in the world. The Museum has more than 99,000 square feet of windows, nearly 300,000 square feet of glass in exhibit cases, 17 elevators, 35,000 electrical outlets, 800 air conditioners and 25 acres of floor space; employs 200 scientists, working in as many offices, and 600 other employees; and stores 34,000,000 specimens in an undetermined number of rooms.

Anyone who visits the Museum must be impressed by the windings and convolutions of its thirty-eight exhibition halls. Those of us who work here know of the Museum's subterranean passageways lined with rumbling steam pipes, of its dark attics stuffed with relics and bones, and of its storage rooms containing all manner of natural history artifacts, from whale skeletons and dinosaur skulls to pre-Columbian jades and mummies.

The growth of the Museum's building has followed, somewhat fitfully and erratically, a master plan created more than a century ago. The Museum was founded in 1869, and for lack of a better space the first collections were housed in the offices of Brown Brothers, a Wall Street firm. The growing collections were later moved

Shakespeare Summerfest

A wide variety of programs, including talks, films, and performances related to the Elizabethan era, is planned in conjunction with the new major exhibition at the Museum, *Shakespeare: The Globe and the World*. For more information on programs listed below, contact Marilyn Roberts at the Education Department, American Museum of Natural History, Central Park West at 79th Street, New York, N.Y. 10024, or call the Museum at (212) 873-1300.

The Lover and His Lass

On Wednesday, July 15, at 7:00 P.M. in the Education Hall, a program of poetry and dance will re-create the ambiance of a candlelit dancing party in a sixteenth-century manor house. *The Lover and His Lass: Dances from Shakespeare's Time*, choreographed by Bhala Jones using sixteenth-century dance forms, is presented by the Ananda Dancers.

Dances for a Winter's Night

This program of dance includes selected sixteenth-century dances connected by quotations from dance manuals of the period. The narrative reveals the manners, morals, and often humorous insights of Renaissance life. *Dances for a Winter's Night* will take place on Tuesday, July 21, at 7:00 P.M. in the People Center, and is presented by Bhala Jones and the Ananda Dancers.

The Book in Shakespeare's Age

Daniel Traister, of the New York Public Library's Department of Rare Books and Manuscripts, will give a talk, *The Book in Shakespeare's Age*, on Wednesday, July 29, at 7:00 P.M. in the People Center.

The New Jersey Shakespeare Festival Events, Drew University, Madison, New Jersey

Lecture Demonstration in Potter's Field Acting Technique with Michael Moriarty and members of the Potter's Field Theatre Company. Saturday, June 27, at 3:00 P.M.

Violence in Shakespeare, a talk with Paul Berry, artistic director, and members of the New Jersey Shakespeare Festival Company. Saturday, July 11, at 3:00 P.M.

Dressing Shakespeare, with Nancy Potts, designer, Eaves Costume Collection. Saturday, July 25, at 3:00 P.M.

American Shakespeare Theatre Events, Stratford, Connecticut

Shakespeare's Histories, a talk by Charles A. Hallett, professor of English at Fordham University. Wednesday, July 8, at 4:30 P.M.

Shakespeare: The Literate Actor, a talk by Bernard Beckerman, professor of dramatic literature, Columbia University. Wednesday, July 15, at 4:30 P.M.

Other Shakespeare Summerfest Events

The American Shakespeare Theatre in Stratford, Connecticut, will present *Henry V*, starring Christopher Plummer, and *Othello*, starring James Earl Jones, from July 7 to September 6.

The New Jersey Shakespeare Festival in Madison, New Jersey, is offering a rotating repertory season, from June 23 to September 6, including *Romeo and Juliet* and *Cymbeline*.

The New York Renaissance Festival of the Arts will re-create the atmosphere of a Renaissance fair during the seven weekends from August 1 to September 13 and Labor Day.

The New York Shakespeare Festival will present *The Tempest* from June 26 to July 26 and *Henry IV, Part 1* from July 31 to August 30. Performances will be given Tuesday through Sunday at the Delacorte Theater in Central Park.

WNET/Thirteen will rebroadcast productions from the BBC/Time-Life series "The Shakespeare Plays."

The Chautauqua Institution of Chautauqua, New York, is sponsoring a one-week program on Shakespeare in July. The featured speaker is Sam Schoenbaum, author of *Shakespeare: The Globe and the World*, the catalog published in conjunction with the Folger Shakespeare Library exhibition.

The Yale Center for British Art is exhibiting Yale University's extensive holdings of Shakespearean art through July 5. The university is also offering a free series of Shakespearean films through August 15.

Bedouin Tent

A collection of Saudi Arabian artifacts is on display in the Roosevelt Rotunda. The focus of the exhibit is a Bedouin tent featuring objects of these nomadic people. The exhibit will also trace Arabian cultural development, from Paleolithic times to the present, through flint tools and points, pottery, and historical photographs.

"Where's the best fishing in the Gulf of Mexico? Just look for an offshore oil platform."

"If you have any doubts, ask one of the men who run sports fishing boats in the Gulf," says H. E. Braunig, a Manager of Environmental Affairs at Gulf Oil. "When they want to guarantee their customers a good day's fishing, they head straight for the oil platforms.

"Twenty universities and thousands of fish say oil platforms don't hurt the environment."

"What happens around the bottom of the oil platforms is ecologically identical to what happens around any natural reef.

"A food chain starts. Mussels, anemones, starfish, anything that likes to live on a solid underwater surface, all come first. Then the fish that feed on them; and so on, until a whole ecosystem builds up.

"Even with the oil platforms, it's life as usual in the Gulf of Mexico—even for the commercial shrimp and oyster fishermen, whose livelihood depends on clean water.

"That's living proof that offshore platforms aren't ecologically destructive. A two-year study by twenty Gulf Coast universities, concluded in 1974, says the same thing.

"Gulf people are meeting a lot of challenges in getting the oil out while preserving the environment. This problem just seemed to solve itself; and with continual environmental monitoring and sampling, on all current and future offshore sites, we intend to make sure it stays solved."

to the Arsenal Building in Central Park. In 1871 the Museum and its sister institution, the Metropolitan Museum of Art, jointly petitioned the state legislature for land and buildings to permanently house and display their expanding collections. The petition, signed by 40,000 prominent New Yorkers, was speedily accepted, and the city offered the Museum a patch of land—which was known at the time as Manhattan Square—adjacent to Central Park.

The Parks Department had been considering turning this tract into an extravagant zoological park, complete with bear pits and a museum of paleontological reconstructions. When The American Museum took it over, it was a dismal site, indeed. As Louis Gratacap, a curator in the young Museum, wrote:

> This region comprised eighteen acres which had been reserved for a park, years before the design of a Central Park was suggested. It included a rugged, disconsolate tract of ground, thrown into hillocks where the gneiss ledges protruded their weathered shapes, or depressed in hollows filled with stagnant pools, and bearing throughout an uncompromising, scarcely serviceable appearance.
>
> The elevated railroad did not then extend beyond 59th Street, the present bridge over the walled bridlepath into the Park was not yet built, and the Museum thus stood isolated both from the Park and from the populous city. The region around was compounded in its pictorial aspect of several discordant yet picturesque elements; it embraced old farms, ruinous landmarks of ancient New York, brand new stores, sanitary modern tenements, bewildering mazes of hovels clustered together over swelling knobs of rocky ledges, and pretty kitchen gardens lying in its deep depressions. The banks of the Hudson retained in places woods as old as New Amsterdam, and the daily stage which rolled up the spacious boulevard to Manhattanville added a suggestive touch of antiquity to all.

The first improvement to the site was the unceremonious eviction of the picturesque squatters with their goats and pigs. The trustees hired Calvert Vaux, one of the designers of Central Park, as the architect of the fledgling Museum. Vaux came up with a magnificent plan, calling for a building three times larger than the British Museum. According to a report submitted to the trustees, Vaux "contemplated for the entire edifice a hollow square whose sides were to be formed of four great buildings 700 feet long, ornate in material and detail, and distinguished by large entrances of architectural dignity and strength." The hollow square would contain two long buildings that crossed in the center, forming four courtyards. The center of the structure would have an enormous tower rising up to the heavens, which appropriately would contain the Hall of the Heavens. Jacob Wrey Mould, J.C. Cady, and other architects enlarged upon and embellished Vaux's plan.

On June 2, 1874, Pres. Ulysses S. Grant laid the cornerstone of the new building. He was attended by a flock of important officials, including three cabinet members, the governor, and the mayor. It must have been an odd sight, with the remaining squatters and livestock looking on as Grant troweled the cornerstone and time capsule into place (the trowel was stolen a few moments later, proof that the good old days of New York were not as

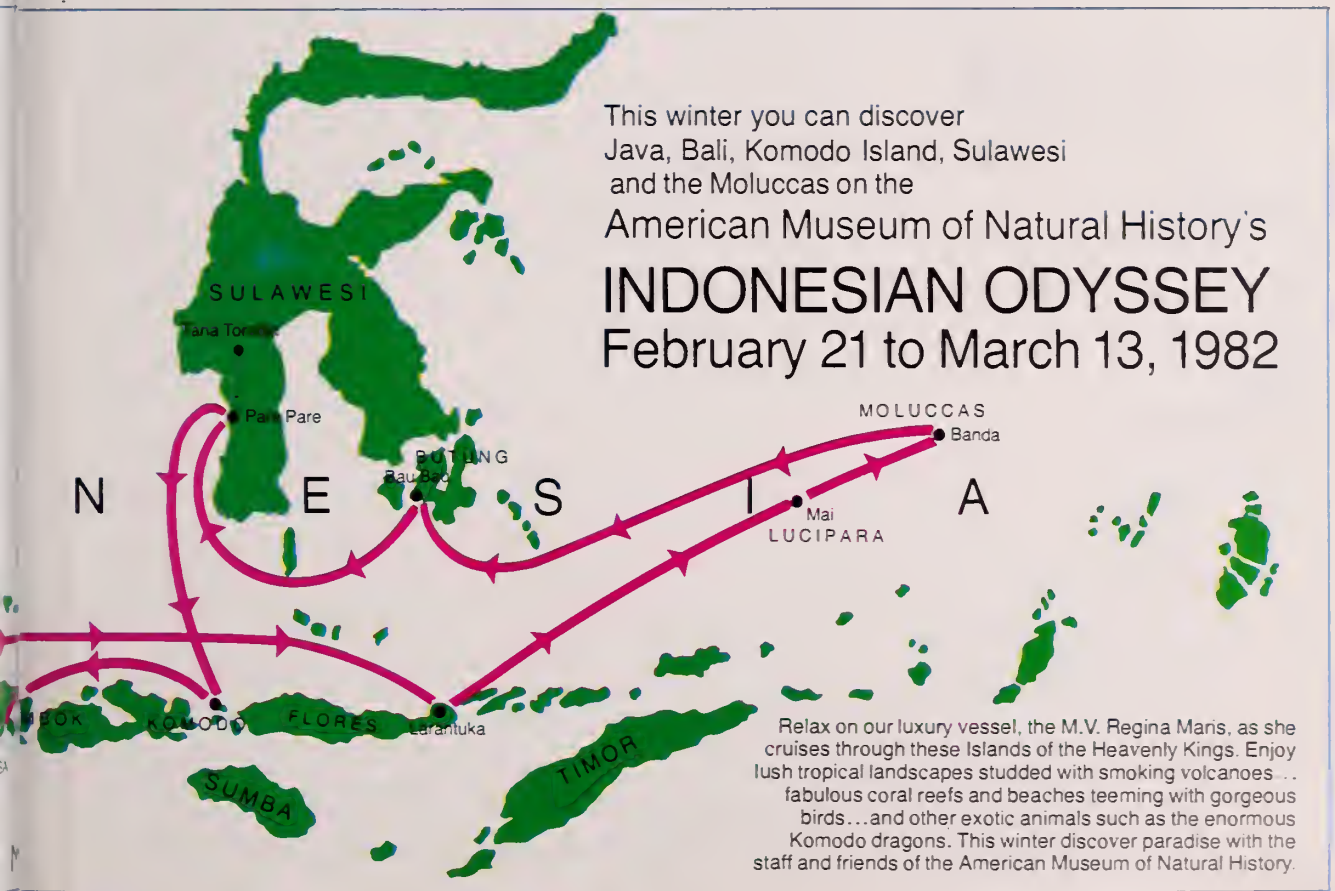
rosy as people imagine). One speaker alluded apologetically to the scene:



To the stranger who comes here today these rugged foundation walls and rough surroundings are not well calculated to make a pleasant impression; but to us . . . it requires but little strain upon the imagination to conceive the speedy occupation of all these vacant lots by substantial dwellings, and to picture to ourselves the spot on which we now stand, known as Manhattan Square, as covered by the proposed Museum of Natural History.

The first building opened to the public in 1878. It was an austere, Victorian Gothic structure that looked out upon a wasteland of rubble and undrained ponds. It was so far uptown that its exhibition halls had virtually no visitors, and at one point, the trustees actually considered closing the place. But better times were ahead, according to Gratacap:

The local isolation which had at first seemed discouraging was in the process of improvement. The Manhattan Elevated Railway pushed forward its tracks to 81st Street and on to Harlem, and brought Manhattan Square into practical union with all quarters of the city. An extraordinary movement northward was soon developed, and the ridges of rock, unpleasantly encumbered with shanties, were blasted to a level, and covered with houses. Centers of population were created, as in 72nd Street and the Dakota Apartments, Saint Agnes' Church at 94th Street with its surroundings, and the growing inhabitation of Riverside Drive. These, spreading, met along lengthening lines of contact, and a population was becoming localized directly at the doors of the Museum.

A Romanesque Revival façade designed by J.C. Cady was added to the Museum in 1889, and in 1893 the east wing was built. These greatly improved the Museum's appearance; in fact, the façade has often been called the finest example of Romanesque Revival architecture in the city. During the next fifteen years, the Museum continued to expand along the designs of Vaux and Mould. By 1899, the west wing, southeast corner wing, and southwest corner wing had been erected. The heating and lighting plant (a squat windowless cube) and a lecture hall were erected by 1903. In 1906 the south wing of the west façade was finished. When construction finally stalled, only one-third of Vaux's original building was complete. In particular, the all-important east façade facing Central Park had not been built, and the Museum started looking at various designs.

In 1911, two architects submitted a plan calling for "an entrance of monumental size" with a "broad and dignified avenue of approach." This idea bounced around for a while, but nothing came of it. Then, when Teddy Roosevelt died in 1919, the Museum decided to turn the east façade into a monument for him. The monument was to "interpret the character of Roosevelt as a naturalist and citizen" and "suggest a lofty standard of idealism through harmonious lines inspired by models chosen from the golden age of architecture." The Romanesque Revival style was abandoned and replaced by an architectural style that has become known as Roman Eclectic—"Roman" because it borrowed various bits and pieces from Roman and Greek models, and "Eclectic" because it borrowed indiscriminately. John Russell Pope, specialist in clas-

sical architecture, designed the Doric-colonnaded façade and interior Memorial Hall (now erroneously called a rotunda). The sculptor James E. Fraser created a massive bronze statue of Roosevelt astride a horse and flanked by an American Indian and an African, symbolic of "Roosevelt's interest in the original peoples of these widely separated countries."

The design also called for a grand intermuseum pathway stretching across Central Park and linking the American Museum with the Metropolitan Museum. When this plan was rejected by the Parks Department, Henry Fairfield Osborn, president of the American Museum, scaled it down to an avenue 500 feet long and 160 feet wide. He fought long and hard for the idea, and was bitterly disappointed by his lack of success; later, he would refer to this as one of the great failures of his life. The memorial, however, was built, and today the statue of Roosevelt, thirty feet high, looks out over the park with dignity.

The Roosevelt Memorial—the last great addition to the Vaux-Mould plan—opened in 1936. During the last half century, all new buildings not called for in the original plan have been constructed in the spaces allocated for courtyards so as to leave room for the completion of the design. These new buildings include the Hayden Planetarium and many other structures of varying degrees of architectural merit. The Museum's entire exterior—including its sheds, storage buildings, and power plant—was designated a National Landmark by the city in 1967. No one knows if this designation includes the incinerator, sawdust chute, and garbage bins tucked away behind the magnificent pink granite façades of the Museum. The original Victorian Gothic building is almost invisible from the outside, and from the inside one can only glimpse its austere structure. Its cornerstone and time capsule, so carefully troweled in place by President Grant, were lost for nearly a century; their location was only rediscovered in 1969 after a diligent search occasioned by the Museum's centennial.

Today, the original plan of the Museum—that of a huge square with an interior cross—is about 60 percent complete. But the dream of one day finishing the plan, essentially Vaux's, but with new architectural styles, is still very much alive.

Douglas J. Preston

Stomatopods (p. 36)

More than half of the sixty-two different species of mantis shrimps described in R.B. Manning's *Stomatopod Crustacea of the Western Atlantic* (Coral Gables: University of Miami Press, 1969) were unknown in the western Atlantic fauna prior to this study. Part of the "Studies in Tropical Oceanography" series, this primary research work summarizes existing knowledge of the region's stomatopods, including distribution records, and contains a bibliography (pp. 350–71). "Geographic Range, Life History Patterns, and Body Size in a Guild of Coral-dwelling Mantis Shrimp," by M.L. Reaka (*Evolution*, vol. 34, pp. 1019–30), examines the relationship between body size and extent of geographical range in coral-dwelling stomatopods. Based on studies of their life history traits and on observation of catastrophic disturbance in shallow coral habitats, the author concludes that large species of hole-dwelling mantis shrimps disperse more widely and are relatively more opportunistic colonizers than small species. Reaka analyzes the ecological and evolutionary consequences of molting in mantis shrimps in "Lunar and Tidal Periodicity of Molting and Reproduction in Stomatopod Crustacea: A Selfish Herd Hypothesis" (*The Biological Bulletin,* vol. 150, pp. 468–90); she investigates stomatopod learning ability and its relationship to behavior in her recent "On Learning and Living in Holes by Mantis Shrimp" (*Animal Behaviour*, vol. 28, pp. 111–15). An illustrated overview of these shrimp-like creatures is R.L. Caldwell and H. Dingle's "Stomatopods" (*Scientific American*, January 1976, pp. 80–89), which includes information on predatory behavior, threat displays, attacks, and competitive ability. Other useful articles by Caldwell and Dingle include "The Aggressive and Territorial Behavior of the Mantis Shrimp *Gonodactylus bredini* Manning (Crustacea: Stomatopoda)" in *Behavior* (vol. 33,

pp.115–36) and "Reproductive and Maternal Behavior of the Mantis Shrimp *Gonodactylus bredini* Manning (Crustacea: Stomatopoda)" in *The Biological Bulletin* (vol. 142, pp. 417–28).

Andean Birds (p. 50)

For a more technical approach to high Andean birds than that found in this issue, see F. Vuilleumier and D. Simberloff's "Ecology Versus History as Determinants of Patchy and Insular Distribution in High Andean Birds" (*Evolutionary Biology*, vol. 12, pp. 235–379). J. Dorst's natural history of *South America and Central America* (New York: Random House, 1967) discusses the landscape, plants, and animals of those areas, and has interesting sections on the high Andes. *Land Above the Andes*, by T. Morrison (New York: Universe Books, 1972), a popular account of wildlife in that mountain range, contains much interesting material on the high Andes, but is flawed by inaccuracies. An excellent field guide to the birds of central Peru, *The Birds of the Department of Lima, Peru*, by M. Koepcke (Wynnewood: Livingston Publishing Co., 1970), includes most of the birds from the high Andes discussed in this issue's article. Useful as reference works are R.M. de Schauensee's *The Species of Birds in South America and Their Distribution* (Neberth: Livingston Publishing Co., 1966), which lists the bird species inhabiting that continent, and *A Guide to the Birds of South America* (Wynnewood: Livingston Publishing Co., 1970), an illustrated manual appropriate for amateurs as well as ornithologists. De Schauensee and W.H. Phelps, Jr., coauthored *A Guide to the Birds of Venezuela*, illustrated by G. Tudor (Princeton: Princeton University Press, 1978), a field guide providing essential information on the physical characteristics, behavior, habitat and range of Venezuela's diverse and plentiful avifauna, comprising nearly 1,300 species.

Multi-Purpose

MUSHROOM CALENDAR

by Orson K. Miller and David L. Largent

- A **calendar** with large spaces for memos
- An **identification guide** to common edible mushrooms
- A collection of beautiful **color photographs** of mushrooms
- A collection of **recipes** using wild mushrooms

First in a series of unique calendars to be published annually.

Calendar will remain useful at the end of the year: the recipes can be cut out and stored, the photographs can be framed for hanging or otherwise be used as decorations, the recipes and photographs can be removed to start a book on edible mushrooms.

An excellent and unusual gift; a mailer is available.

Now at a special prepublication price. Offer expires Sept. 1, 1981

All prices include postage and handling.

$5.95 (without mailer)
$6.95 (with mailer)
Regular price
$8.80 and $9.95, respectively.
Calif. residents add 6%.

Send check or money order to

MUSHROOM CALENDAR

A Fish Story

The salmon's decline in the Pacific Northwest is a tale with many villains and few heroes

by Raymond Sokolov

The best fish story I know revolves around a Finnish-American woman called Vanessa and an extremely large salmon. Some years ago, Vanessa was spending a weekend with a friend in Cooperstown, New York. The salmon arrived the same weekend, brought from Alaska by a neighboring plutocrat. Vanessa's host heard about the majestic fish and knew that it was languishing in the refrigerator of its owner, whose culinary ineptitude was local legend. Vanessa, a cook of skill and daring, resolved to liberate the noble salmon and give it fitting gastronomic treatment. Seizing a moment when the plutocrat and his family were busy at tennis, she crept into the house, purloined the *Oncorhynchus*, and poached it to a turn in her host's kitchen. She boned and glazed the fish and returned it to the owner's refrigerator.

In fact, Vanessa only returned half the salmon and kept the other half for the delectation of herself and her friends. It seemed only fair, in light of the service rendered. And when the rightful owner saw the beautifully decorated, flaky, pink chaudfroid salmon ready to eat in his fridge, he was delighted.

Not all the salmon stories have such happy endings. The Pacific Northwest, once a salmon paradise, is today a region made glum and angry by the salmon's decline. As an outsider, I want to speak with caution about Pacific salmon. It is a most complicated subject. Ask almost anyone in Washington State about salmon and the usual reply is a shake of the head, because the salmon question has as many sides as a sockeye has scales.

Consumers blame industrial polluters. Environmentalists lambaste the power companies that built the dams that block the rivers and impede salmon from making their way upstream to spawn. Non-Indian fishermen bristle over the federal court ruling that compels them to share the shrinking salmon catch with Indian fishermen on a strictly equal basis. But the Indians, prospering materially because of this judicial interpretation of their treaty rights, will still probably never regain the salmon-centered way of life they led before the coming of the white man.

Northwest Coast Indians had some 9,000 years in which to perfect an intricate salmon-catching technology, a salmon cuisine, and various rituals celebrating the importance of salmon in their culture. Hilary Stewart's exhaustive *Indian Fishing: Early Methods on the Northwest Coast* (University of Washington Press) is a fascinating encyclopedia of salmon lore that shows, for example, exactly how to make bentwood hooks and how the Nootka tribe trolled for salmon in open water just before the run. Stone sinkers, bone barbs, spruce-root lashings, leaders of human hair or doeskin or cedar bark twine—all these natural materials were combined laboriously, baited with fish caught in small stone dams, and run out on a long line. The fisherman fastened the line to his paddle handle so that he could locomote and make his baited hook move at the same time.

Other fishermen used harpoons or gaff hooks carved from antlers and elaborate nets made of willow-bark twine or homespun nettle fiber. In rivers, they could intercept running salmon with traps and weirs.

Indian salmon cookery was also a sophisticated business. Watertight boxes and baskets were filled with water; then hot stones from a campfire were added with tongs. After the stones made the water boil, in went pieces of salmon in an openwork basket.

Lacking metal ovens, the Indians dug steam pits in the ground or cooked split salmon over heated rocks, methods very close to the East Coast clambake.

The simplest and most famous method of salmon cookery in the Pacific Northwest was to roast the fish over a wood fire. Split salmon were held flat on roasting tongs or skewered on crossed sticks. The tongs and sticks had sharp ends so that they could be stuck in the ground at the edge of the fire. The whole apparatus was tilted slightly, and the salmon extended over the heat. First one side of the fish was roasted, then the other.

Traditional Indian salmon roasting continues to be practiced widely in Washington. The alderwood typically used in the process imparts a superb flavor to the fish, as I can attest, having tasted some that had been cooked over alder chips on a not-so-picturesque but effective metal grill at an open-air takeout counter in Seattle.

Roast salmon was much more than a gourmet treat for Northwest Coast Indians in the old days. Rivers clogged

Photographs by Adelaide de Menil

with salmon were a guarantee of survival all through the year. But like all staple food sources, salmon had to be stored and preserved for the months when fresh salmon wasn't available. Without refrigerator-freezers, Indians built large smokehouses and drying racks and perfected the arts of drying and smoking salmon to a high level. Some fish were half smoked, for immediate eating. That way the flesh was still soft. Other fish were fully dehydrated by longer smoking so that they would keep through the winter.

On a recent visit to Lummi Island, a settlement in the north part of Puget Sound accessible by ferry, I bought some of this "hard-smoked" salmon, which had been prepared by Lummi Indians. It resembled beef jerky in its tough, brittle texture and salty taste. During the drive back south to Seattle, which was frequently whited out by a freak fall blizzard, I understood graphically how earlier generations of Lummis and their coastal neighbors had found this preserved fish a handsome and convenient protein source in cold weather.

Left: Split salmon, skewered on crossed sticks that hold them flat, are roasted over a wood fire. Below: Salmon are hung in a smokehouse to preserve them.

Necessity taught the Indians to eat every part of the salmon—from cheeks to spine. Even salmon roe were hung in strips and dried or smoked. Some Indians put roe in bags made from deer stomachs and hung the bags in their smokehouses. Each day they would knead the bag until the moisture evaporated and the eggs turned into a kind of cheese. Another route to the same result involved burying the roe in a three-foot pit lined thickly with maple leaves. Holes poked in the leaves at the bottom of the pit allowed oil to drain away. After two months, the eggs turned to cheese and could be eaten plain or boiled with water for soup. Some Indians preserved salmon roe by leaving it to cure in saltwater.

None of this salmon-based economy could have occurred without the seemingly supernatural, superabundant annual return of the fish from saltwater to freshwater. Each year, grateful and awe-struck Indians greeted the arrival of the first salmon with joyful celebration and a variety of ritual observances.

When a Kwakiutl troller caught his first nine salmon, he clubbed them only once, stunning but not killing them. Then he strung them on a twisted cedar withe, tied it in a hoop, put the hoop around his neck, and prayed: "I do not wish to club to death your souls so that you may go home to the place you came from, Supernatural Ones. . . ."

After eating the first salmon of the

season, the family wiped their hands on cedar bark but did not wash them. Any bones and leftovers were thrown into the sea, along with the new mats used as a table, to insure a repetition of the run the following year.

These days, no one practices these rituals, but the Indians of our Northwest Coast have found new ways to foster and control the life cycle of the salmon. The Lummis, for example, manage a modern program of aquaculture. And like other Indians in the area, they have benefited from a federal court decision handed down by Judge George H. Boldt in 1974. Boldt ruled that treaties between Indians and the federal government signed in 1854, which guaranteed Indians the right to fish "in common" with non-Indian fishermen, had in fact reserved 50 percent of the catch to the tribal signatories.

Overnight, the relatively small tribal fishing fleet, which before the decision had only been able to catch 10 percent of the commercial salmon in the area, now had a positive right to half. Higher courts have upheld Boldt, and today salmon fishing in Puget Sound is so strictly regulated that every salmon caught must be officially tagged as Indian or non-Indian. Since there are fewer Indian fishermen than white, the season for Indians is substantially longer. To maintain as fair a balance as possible, careful records of the progress of the catch are stored in a computer at the University of Washington. The Boldt decision also secured Indians an equal role in the administration of the new regulations, and at the fishery school on Lummi Island, Lummis are learning to run computer terminals that have access to the salmon records at the university. They are also learning other dry-land skills that will help them play a complete role in the brave new world of equal salmon opportunity. But even Indians suddenly in full enjoyment of their treaty rights must face the fundamental problem of exploiting a fragile and diminished fish population with intelligence. Even if they approach each year's run with their traditional reverence and spirituality, they can never restore the balance of supply and demand that once obtained on the precolonial, sparsely populated shores of Puget Sound.

Raymond Sokolov, a writer with an interest in the history and preparation of food, is editor of Book Digest.

Two Recipes from *The Market Notebook,* a collection of recipes from the Pike Place Market in Seattle, compiled by Pamela Sovold, Margaret Wherrette, and Eilisha Dermont (Madrona Publishers, Seattle)

Baked Salmon with Vegetables

The fish is covered with a thick layer of vegetables and baked in tightly closed foil (really steamed). Good straight from the oven, it is even better the next day, served cold.

Buy a whole fish and have your fishmonger book-fillet it, leaving in the backbone. To book-fillet means to cut the fish in such a way that the fish opens like a book on both sides of the spine. In this recipe the combination of the backbone and the wine makes an amber gelatin that sets when refrigerated and tastes sensational. Serve the fish and gelatin with fresh mayonnaise. Superb!

To prepare, mix together chopped celery tops, chopped onion, minced garlic, chopped green and red peppers, parsley, and jalapeño pepper. How much of each ingredient depends on the size of your fish; you want to put a one-half inch covering on it. Lay your fish on a large piece of foil in a baking pan. Cover with the chopped vegetables. Squeeze the juice of one lemon over the top and sprinkle with a tablespoon each of dillweed and sweet basil. Top with one-half cup of white wine. Seal the foil tightly. Bake at 375 degrees until fish flakes.

Fish with Rhubarb Sauce

- 2 cups rhubarb, cut in small pieces
- ½ cup tomato sauce
- 3 tablespoons olive oil
- 2 teaspoons sugar
- ½ cup water
- Salt
- 1 pound salmon, cut in pieces

Wash rhubarb well. Peel off hard skin, if any. Cook all ingredients (except fish) together for about thirty minutes. When rhubarb is cooked thoroughly, add cut up pieces of fish and simmer until fish is done.

Yield: 3–4 servings

JETTA: THE GREATEST COLLECTION OF VOLKSWAGENS EVER ASSEMBLED UNDER ONE ROOF.

Want us to run that by again? It's really not as crazy as it sounds. Because the Jetta just happens to combine the best features of every other Volkswagen we make.

On the road, for example, the Jetta handles like a Scirocco.

Which is only natural.

Since the Jetta is like a Scirocco.

With rack-and-pinion steering, front-wheel drive, independent 4-wheel suspension and a powerful CIS fuel-injected engine.

Inside, the Jetta is like our elegant Dasher.

With a luxurious amount of room, and a surprising amount of luxury.

And at the gas pump?

You guessed it.

The Jetta's like a Rabbit.

In fact, it gets an EPA estimated 25 mpg, 40 mpg highway estimate. (Use "estimated mpg" for comparisons. Your mileage may vary with weather, speed and trip length. Actual highway mileage will probably be less.)

Of course, the best thing about the Jetta isn't only that it's like a Scirocco, a Dasher or a Rabbit. The best thing about a Jetta is that it's also like, well, a Jetta.

With sleek European styling, sophisticated German engineering, and a trunk so well designed it can easily hold eight suitcases.

When you consider everything a Jetta has to offer, it's no wonder so many people are adding one to their car collections.

After all, how often can you acquire an entire collection in one car?

ALL OUR BEST IDEAS IN ONE CAR. JETTA.

The Possibilities are Endless.

Six-mode exposure control.
System versatility. Newer electronics for wider applications.

The Canon A-1 is one of the world's most advanced automatic SLR cameras. Combining the finest in optical and mechanical engineering with the most sophisticated electronics, it's technology applied to give you the ultimate in creative control. At the touch of a button.

Depending on your subject, you can choose from six independent exposure modes to achieve the results you want:

1 Shutter-Priority: You select the shutter speed, to freeze the action and prevent camera shake or create an intentional blur. The A-1 automatically selects the appropriate lens opening.

2 Aperture-Priority: Control the area in focus by selecting the lens opening for the effect you want. The A-1 matches with the right speed.

3 Programmed: When you need to shoot fast, just focus. The A-1 will select *both speed and aperture* for great results.

4 Stopped-Down: For extreme close-up or specialized photography, a bellows, a microscope or almost anything can be attached to the A-1. It's still automatic.

5 Flash: Totally automatic flash photography, of course, with a wide variety of Canon Speedlites to choose from.

6 Manual: Yes. For those times when you absolutely want to do it all yourself. To experiment. To explore the possibilities.

Programmed 350 95

There are over forty fine Canon lenses ranging from Fish Eye to Super Telephoto, plus accessories to meet every need. If you can't photograph your subject with a Canon A-1, it probably can't be photographed.

From the sophistication of its LED viewfinder display, to a ruggedness that allows up to five-frame-per-second motor drive, the Canon A-1 represents an incredible technology. At a price that makes owning one a definite possibility

For years foreign car manufacturers have boasted about their gas mileage, standard features and interiors. But now, there's a car that beats the imports at their own game. Cimarron by Cadillac.

As the chart shows, Cimarron has features the imports have, plus Cadillac comfort and convenience, with reclining body-contoured bucket seats and perforated leather seating areas. Cimarron has front-wheel drive, just as the Cadillac Eldorado and Seville do. It comes with Cadillac's exclusively tuned, road-hugging touring suspension and a four-speed manual transmission including overdrive. What's more, Cimarron behaves like a civilized car should. Nimble . . . easy to maneuver . . . with a smooth, refined ride.

If you've been thinking about buying an import, it's time to re-think your decision. It's time for Cimarron.

Due to limited initial production, Cimarron is not available at all Cadillac dealers at this time.

Aware that volcanoes played a part in Maya prehistory—and with vivid memories of climbing an erupting Guatemalan volcano in 1969—**Payson D. Sheets** surveyed El Salvador for a Maya archeological site that would reveal the effects of volcanism. In 1978 his investigations led him to Cerén, a Pompeii-like site that had been partly exposed by bulldozing but whose potential value had not been appreciated. His initial excavations proved most rewarding, but the current civil war in El Salvador has interrupted the work. In the meantime, Sheets, an associate professor in the Department of Anthropology at the University of Colorado at Boulder, is conducting an experiment based on his archeological research. Having discovered that fractured obsidian edges are much sharper than surgical steel blades, he is collaborating with an eye surgeon to apply the ancient technology for making stone tools to the manufacture of scalpels.

"I became totally enamored of avocets and stilts the first time I saw them in the spring of 1974," reports **Tex A. Sordahl,** an assistant professor of biology at Luther College in Iowa. His interest grew as his familiarity with the birds' behavior increased. "I even endured my friends ribbing me about being a 'legs man.'" Sordahl studied avocets and stilts intensively during 1977, 1978, and part of 1979 at two sites in Utah: a private hunting area known as the Barrens and the Bear River Migratory Bird Refuge. He hopes to observe the behavioral ecology of mountain plovers in Colorado as his next project and to continue his work on the antipredator behavior of shorebirds.

Randall R. Reeves, a research associate with the Canadian government's Arctic Biological Station in Quebec, spent several months observing the Eskimo narwhal hunt. Why narwhals? "They live in remote areas, little is known about their lives, and the value of their tusks creates the potential for serious conservation problems." A graduate of the University of Nebraska in Lincoln and of Princeton University, Reeves is studying the history of exploitation and the current status of the humpback whale in the western North Atlantic. His research on narwhals was supported by the Peoples' Trust for Endangered Species in England.

Coauthor **Edward Mitchell** is a research biologist with the Canadian Department of Fisheries and Oceans and serves on the Scientific Committee of the International Whaling Commission. Concerned with the ecology and population dynamics of North Atlantic whales, Mitchell has also published articles on fossil marine mammals.

Europe's greatest wild bird artist creates his first porcelain bowl

Shown less than actual size of 10" in diameter.

'The Game Bird Bowl' by Basil Ede.
Hand-decorated in 24 karat gold and issued in limited edition.

The art of Basil Ede is known and collected the world over. It has earned him critical acclaim as "the outstanding wild bird portraitist of his generation." And he is one of the few British artists ever honored with a one-man show at America's Smithsonian Institution.

'The Game Bird Bowl' is Ede's first porcelain bowl. A work unlike any other he has ever created. An achievement to be treasured, and kept in your family for generations. And you are invited to acquire this work now.

Crafted in fine white porcelain—the perfect background for the sweeping lines and rich natural hues of Basil Ede's art—the bowl will be a showpiece. Its subject is the beautiful Black Grouse, portrayed in its natural habitat on the Scottish moors. To add the final touch of elegance and refinement, the bowl will be hand-decorated, at the crown and at the base, with bands of pure 24 karat gold. The original issue price is $150.

Each bowl will be produced to individual order by Franklin Porcelain, the only house ever authorized to issue Basil Ede's work in porcelain. Responsibility for its crafting will be entrusted to our associates in Japan, where artistry in porcelain represents a heritage some four centuries old.

In keeping with established tradition for fine works in porcelain, the bowl will be issued for a limited period of time. Advance orders are being accepted until August 31, and the bowl will be withdrawn forever at the end of 1982. A Certificate of Authenticity, together with a commentary on the art of Basil Ede, will accompany the work.

To acquire 'The Game Bird Bowl', please return the attached form by the advance ordering deadline of August 31, 1981.

Born in Scotland, **Robert M. Arnold** received a Ph.D. in physiological plant pathology from Simon Fraser University in British Columbia and has been assistant professor of biology at Colgate University for the past five years. A "childhood interest in trains, professional training in biology, and a delight in being out in the country looking at plants" all came together, he says, in research on the reproductive and dispersive strategies of plants that grow along railroad tracks. Arnold is currently comparing insect pollination in such weeds as dwarf snapdragon, an annual that grows well on railroad cinders, and butter-and-eggs, a perennial that is widespread along roadsides and waste places.

The idea of studying New York City's bicycle messengers was suggested to **Jack Kugelmass** (left) by **Yoav Levy**, whose photographs illustrate the story. In addition to the opportunity to learn about these modern "mavericks," Kugelmass saw the chance to earn some money in his role as a participant-observer. "In fact," he says, "given the limited prospects for anthropologists' careers, I found that the line separating me from the messengers became increasingly blurred." Kugelmass is an associate in anthropology at the Max Weinreich Center for Advanced Jewish Studies at the YIVO Institute in New York City.

The Mayans called their city Uxmal.
You'll call it unforgettable.

A world of wonder. A world of value.

MEXICO

You'd have to crisscross the globe to find all the vacation riches waiting for you in Mexico. In one country, one visit... which we're sure will lead to many more... you'll experience an unforgettable panorama of sights and sensations. The temples of Uxmal beckoning you to the top. The silver shops of Taxco tempting you to stop. Guadalajara's music. Cozumel's crystal seas. Puerto Vallarta's balmy blend of elegance and ease.

And our world of wonder goes on. A fascinating land made even more appealing as Mexico maintains its reputation as one of the great travel values. The extraordinary vacation. At a most ordinary price.

The Importance of Mother's Milk

Among its other significant ingredients, human milk contains a hormone, known as epidermal growth factor, that stimulates cell division

by Graham Carpenter

Reproduction of the species is considered to be the driving force in the evolution of biological systems, and nature has a large investment in a newborn organism. This is particularly true of humans and other large mammals that have relatively long gestation periods and usually produce only one or two offspring at each birth. Survival of these newborns is critical to the continuance of each species, and for almost all mammals, milk is the material that provides total nourishment during the initial stages of life. The exception is the human species, which in the last several decades has in large numbers shifted from milk to substitutes.

At the turn of the century approximately 50 percent of all newborn babies in the United States were breast-fed for at least the first twelve months of life. Recent surveys indicate that during the 1970s about one in three babies was nursed during the first month of life. Concurrently, the duration of breast-feeding declined rapidly, to the point that about 5 percent of all infants were nursed until six months of age and 1 percent until twelve months of age. At present there is a shift among new mothers to return to breast-feeding, but this group is small in relation to the total population. In today's era, when information is prized and decision making based on biological instinct is, perhaps unfortunately, frowned upon, it would seem that data about such an important commodity as milk (and its commercial formula substitutes) should be of concern to both the public and the medical profession.

Too frequently the assumption is made that "milk is milk," and whether a newborn human drinks mother's milk or cow's milk is of no large consequence. A second assumption is that today's technology is so advanced that artificial formulas can duplicate the quality of natural human milk. Both of these assumptions are incorrect. Comparison of the composition of milk from various species shows that there exist significant qualitative and quantitative differences, which seem to reflect the varying needs of each species for proper development in early life. For example, compared to human milk, the milk of the bovine species has twice as much protein, which after digestion provides the newborn with a source of raw materials, that is, amino acids, for muscle growth. This increased protein content reflects the needs of almost all newborn animals (excluding humans) to grow rapidly in order to avoid predators, become independent quickly, and survive. A newborn cow, for instance, will double its birth weight in about 50 days, whereas a newborn human requires 180 days. Because human milk is relatively low in protein does not mean that it is insufficient in that respect. Human infants do not need to add bulk as rapidly as other newborn animals, but have different needs, including maintaining a higher rate of brain growth.

Myelination—the surrounding of nerve axons with a lipoprotein membrane, or sheath, necessary for the proper conduction of nerve impulses—is an important process of human brain growth in the first year of life. Myelination requires substantial quantities of lipid, and human milk has a relatively high lipid content. Lipid intake is also important for the baby of lower weight who, to maintain a proper body temperature, must produce fat for insulation.

Comparative analyses of milk compositions provide many examples such as these and quite strongly demonstrate that each species has during its evolution devised a milk composition that is optimal for its specific needs. The high degree of sophistication of the biological mechanisms that control the composition of milk is demonstrated by the capacity of mothers of preterm babies to produce a milk with a higher content of protein and lipid than is found in the milk of mothers of full-term babies. Nature apparently provides the preterm, low-weight infant with extra protein to increase its body mass, or weight, and with extra lipid to stabilize body temperature and to provide more fuel for energy production.

Most of our present knowledge of milk composition concerns those components that are present in milk in the largest amounts—macronutrients such as protein, carbohydrate, and lipid. There is also a reasonable body of data describing the levels and different types of minerals and vitamins. Milk, however, is more complex than is currently understood, and there are increasing feelings in the scientific community that, in addition to satisfying nutritional needs, milk may provide other, subtle but important factors for growth and development in the newborn. For example, the antibodies passed through milk from mother to child help the newborn, whose ability to produce antibodies has not fully developed, resist microbial infections. Breast-fed babies do, in fact, suffer fewer infections, par-

PAY TO THE ORDER OF Save the Children 19 $16.00

Sixteen and no/100 ~~~~~ DOLLARS

(Signature) _____

MEMO: *U.S. Income Tax Deductible Monthly Sponsorship*

(Your Address) _____

City & State _____ Zip _____

Fill out this check (or use your own) and save the children

For only 52¢ a day (just $16 a month) you can befriend a needy child through Save the Children. Your money, combined with that of other sponsors, can breathe new life into an impoverished village...help hardworking people in their fight for dignity...turn despair into hope for a child who has known only disaster. 52¢ may not buy much where you live. But for the poorest of the poor, where the need is so desperate, it can work miracles.

For your first monthly sponsorship contribution, just fill out and sign the check at the top of this page (yes, as long as you indicate your bank name and account number, it is negotiable). Mail the entire page to Save the Children. Of course, you may use your personal check if you prefer.

TELL US HOW YOU WANT TO HELP BY ANSWERING THESE QUESTIONS.

Your name _____ (please print)

Address _____

City _____ State _____ Zip _____

1 What kind of child would you like to help?
☐ Boy ☐ Girl ☐ Either

2 What geographical area are you interested in?
Urgent need exists in all the areas listed below. Select an area, or let us assign a child where the need is greatest.

☐ **Where the need is greatest**
☐ Africa
☐ American Indian
☐ Bangladesh
☐ Chicano (U.S.)
☐ Colombia
☐ Dominican Republic
☐ Honduras
☐ Indonesia
☐ Inner Cities (U.S.)
☐ Israel
☐ Lebanon
☐ Mediterranean
☐ Mexico
☐ Nepal
☐ Southern States (U.S.)
☐ Sri Lanka (Ceylon)

3 Would you like a picture of your sponsored child?
Shortly after we select a child for you, we can send you a photograph and brief personal history, if you desire.
☐ Yes ☐ No

4 Would you like to correspond with your sponsored child?
If desired, correspondence can help build a meaningful one-to-one relationship. Translations, where necessary, are supplied by Save the Children.
☐ Yes ☐ No

5 Would you like information about the child's community?
When you become a sponsor, your funds are used to help children in the most effective way possible—by helping the entire community with projects and services. For health care, education, food production, and nutrition. Several times a year you can receive detailed reports on these community activities which provide permanent improvements to the child's environment. Would you like to receive such information?
☐ Yes ☐ No

6 Do you wish verification of Save the Children credentials?
Save the Children is indeed proud of the handling of its funds. Based on last year's audit, an exceptionally large percentage (83.5%) of each dollar spent was used for program services and direct aid to children and their communities. Due to volunteered labor and materials, your donation provides your sponsored child with benefits worth many times your total gift. Would you like to receive an informative Annual Report (including a summary financial statement)?
☐ Yes ☐ No
(A complete audit statement is available upon request.)

7 Would you rather make a contribution than become a sponsor at this time?
☐ Yes, enclosed is my contribution of $_____.
☐ Check here for general information about our unique programs for aiding impoverished children.

"We wanted this collection to have it all! The great bands, the soloists and the singers. It's good to know this music is all here . . . all together . . . for now and the future."

—Count Basie

The greatest authorities on the music of America's big band era—musicians and music critics alike—have joined together, for the first time, to assemble *the definitive collection of big band recordings.*

This is a collection unlike any issued before. For the bandleaders, writers and critics who comprise this panel are the very same ones who shaped the big band era.

These experts enlisted the cooperation of the record companies which now hold the *original master recordings* of the big name bands. Thus, the panel was able to make its selections from virtually every big band performance ever recorded—*making this the first such collection ever assembled from all the big band record labels.*

As a result, this will be the most complete, comprehensive and authoritative collection ever devoted to big band music. And it will be the first ever available on *proof-quality* records of exceptional fidelity.

All the great bands, singers and soloists in their greatest recorded performances

The Archive Collection of *The Greatest Recordings of the Big Band Era* will be all-encompassing. A collection which reflects the musical diversity of the era. The crisp swing of Benny Goodman and Artie Shaw, the relaxed rhythm of Count Basie and Jimmie Lunceford, the bright dixieland of Bob Crosby, the sophisticated stylings of Duke Ellington, the dreamy delicate sounds of Ray Noble, the soft, sweet music of Guy Lombardo and Sammy Kaye. It will also include:

The musical forerunners of the era—Paul Whiteman, with Bing Crosby and Bix Beiderbecke; Fletcher Henderson, who influenced Benny Goodman and many others; the early sounds of Glen Gray and Fred Waring.

The nostalgic themes of the big bands—Glenn Miller's "Moonlight Serenade" . . . Tommy Dorsey's "I'm Getting Sentimental Over You" . . . Louis Armstrong's "When It's Sleepy Time Down South" . . . Vaughn Monroe's "Racing with the Moon."

The greatest hits of an entire generation—Charlie Barnet's "Cherokee," Duke Ellington's "Take the 'A' Train," Artie Shaw's "Frenesi," Frankie Carle's "Sunrise Serenade," Tommy Dorsey's "Opus One," Eddy Duchin's "Stormy Weather," and Benny Goodman's "Sing, Sing, Sing," with Gene Krupa.

The big band vocalists that audiences loved . . . and still remember. Frank Sinatra with Tommy Dorsey, Peggy Lee with Benny Goodman, Doris Day with Les Brown, Anita O'Day with Gene Krupa, Bob Eberly and Helen O'Connell with Jimmy Dorsey. And many more, including Perry Como, Lena Horne and Ella Fitzgerald.

The ultimate collection of original big band recordings

This is a collection that would be difficult—or impossible—for any individual to assemble. For these selections have been drawn from the archives of all the major record companies . . . and such vintage labels as Brunswick, OKeh, Vocalion, Bluebird and Perfect.

Many of these recordings—like Wayne King's "Melody of Love"—have been *unavailable for years.* Others are *hard to find recordings* of early radio broadcasts . . . such as Frank Sinatra's emotional farewell to the Tommy Dorsey Orchestra, doing his spectacular rendition of "The Song Is You." Still others were only released on 78s—and *never re-issued:* Eddy Duchin's "Ol' Man Mose," and Bob Crosby's "Black Zephyr."

In many cases, the panel considered several *different* versions of the *same* song, before selecting a particular recording for the collection. Thus, *every* selection will be a classic performance. An original recording of the era . . . recaptured on records of superior listening quality.

Superb quality for today's audio systems

These records will be produced to the highest standards possible by The Franklin Mint Record Society—judged by audio experts to produce some of the finest records available today.

Each recording will first undergo a painstaking restoration process—electronically "cleaned" groove-by-groove to eliminate extraneous surface noise and preserve the original brilliance of the music.

The records will be pressed in a dust-free "clean room" using a special vinyl that contains its own anti-static element. This meticulous pressing technique, together with the special record vinyl, results in a more rigid, durable and dust-resistant record. A *proof quality* record that actually *sounds better* than the original—and may be played through any audio system.

Hardbound albums and big band histories provided

In keeping with the importance of this collection, special hardbound albums have been designed to house and protect all one hundred proof-quality records.

Each album holds two long-playing records, together with an expertly written commentary—prepared by members of the advisory panel, and illustrated with photographs of the bands. A complete reference index to bandleaders, songs and solo artists will also be provided.

Available by subscription only

If you remember the big bands . . . if you've ever wished to relive the music of that period . . . or if you've only just discovered this unique sound in American popular music . . . *this* is your opportunity. An opportunity to share and enjoy—with all the members of your family—the unforgettable sound of the big bands.

The collection may be acquired only by direct subscription. It will not be sold in record stores. To subscribe now, mail the attached application to The Franklin Mint Record Society, Franklin Center, Pennsylvania 19091. Please do so by August 31, 1981.

Strict record pressing standards, and audio and visual inspection, assure high quality. Ordinary records (left) have static charges that attract dust, causing surface noise. But the special anti-static vinyl used in Franklin Mint records (right) assures clearer sound. Electrostatic meter tests show that the Franklin Mint record has only one-fifth the static charge of ordinary records.

The Advisory Panel

COUNT BASIE for more than 40 years, leader of one of the most consistently swinging bands in history.

LES BROWN outstanding writer, arranger and leader of one of the era's most popular dance bands.

DAVE DEXTER, JR. a record producer for 31 years, former *Down Beat* editor and author of *The Jazz Story* and *Playback.*

LIONEL HAMPTON a leader whose exuberance has inspired musicians and audiences alike for more than five decades.

WOODY HERMAN who continues to be one of the most popular and successful of all leaders—discoverer of many talented musicians.

HARRY JAMES a brilliant trumpeter of both beautiful ballads and rip-roaring swing.

SAMMY KAYE "Mister Swing and Sway," master of the sweet sound—always popular, always danceable.

NEIL McCAFFREY music critic and editor of *American Dance Band Discography* and *The Complete Encyclopedia of Popular Music and Jazz.*

GEORGE T. SIMON music critic, record producer, author of the definitive work on dance bands—*The Big Bands*—and *The Best of the Music Makers.*

RICHARD SUDHALTER jazz critic of The New York Post, author of *Bix: Man and Legend,* and a widely respected jazz cornetist.

JOHN S. WILSON jazz and popular music critic of The New York Times, author of *Jazz: The Transition Years, The Collector's Jazz: Traditional and Swing, The Collector's Jazz: Modern.*

ticularly of the gastrointestinal tract, than formula-fed babies.

Hormones, the body's chemical messengers, are other kinds of molecules present in milk. Most hormones are either proteins (insulin, for example) composed of many amino acids or have chemical structures related to steroids. A characteristic of all hormones is that they are present in body fluids in exceedingly small quantities compared with other components. Nevertheless, hormones play a vital role in regulating body chemistry and physiology. For instance, an individual can ingest large amounts of carbohydrates but unless insulin is present the carbohydrates will not be utilized properly. Similarly, other hormones control virtually all processes that the body carries out. There are a number of hormones known to be present in human milk, but their significance has not been demonstrated. This does not mean these molecules have no significance; it simply means that none is yet understood.

Also present in milk is an interesting class of hormones—often referred to as growth factors—that controls cell growth and differentiation. Research in this area is relatively new and it is very likely that many more growth factors will be identified in the future. Of those now known, one of the most thoroughly investigated is epidermal growth factor, or EGF. Epidermal growth factor is a small protein molecule composed of fifty-three amino acid residues. Discovered in the early 1960s in mice by Stanley Cohen, a biochemist at Vanderbilt University, this hormone has since been detected in many mammalian species. It is present in almost all human body fluids, including milk, where its concentration (approximately thirty nanograms per milliliter) is quite significant for a hormone.

The classic procedure for determining the function of a hormone has been to surgically remove the hormone-producing organ and record the resultant effects of the hormone deficit. The observed effects can be attributed to the hormone deficit if the effects are prevented or reversed by injection of the hormone into the animal. This experimental strategy is not always possible, however. In the case of EGF, it is not known where in the body the hormone is produced, and the available evidence suggests that there are probably several distinct sites. Therefore, it has not been possible to determine unequivocally what functions EGF serves. There are experiments, however, that demonstrate quite interesting biological effects when EGF is administered to animals. These results probably provide good clues to the natural function of this hormone.

Cohen's pioneering studies demonstrated that EGF had a pronounced stimulatory effect on the growth and differentiation of the outermost layer of the body, the epidermis of the skin—hence the name epidermal growth factor. In those initial experiments, newborn mice were injected daily with small quantities of EGF, and an intriguing result was observed. Normally, a newborn mouse is born with its eyelids shut and, without exception, its eyelids open at thirteen to fourteen days after birth. But baby mice injected with the epidermal growth factor opened their eyelids in seven days. The proliferation of skin cells in the eyelid area and their differentiation, a process called keratinization, had been accelerated. Later studies have demonstrated that the effect was not limited to the eyelid area; all areas of the epidermis were similarly stimulated to proliferate and keratinize in newborn animals treated with EGF.

More recent experiments have shown that EGF stimulates epithelial tissues other than the skin. The entire gastrointestinal tract is lined with epithelial tissue, and several studies have shown that EGF stimulates cell division and accelerates certain differentiation events in this tissue. During development in the perinatal period, the cells of the gastrointestinal tract begin to produce hydrolytic enzymes—protein molecules required for the digestion of food. The rates of activity of these enzymes are generally low at birth and increase as the infant matures. If these digestive enzymes do not develop at the correct time, the infant is less able to utilize food to sustain its nutritional requirements, and obviously, a long delay in the maturation of the digestive enzymes has serious consequences. A recent study by a Canadian group at the University of Sherbrooke in Quebec reports that when newborn mice are injected with EGF the maturation of several digestive enzymes is accelerated. Thus the hormone may have a significant function in the growth and development of this important system.

A second critical transition for the newborn infant occurs at birth, when maternal oxygen, which was delivered *in utero,* is no longer available; suddenly oxygen must be taken in from the air and, via the lungs and circulatory system, made available to the tissues. Failure to adjust successfully to atmospheric oxygen at birth creates a respiratory distress syndrome called hyaline membrane disease. This is, of course, a serious condition, and one that is seen not infrequently in the baby born prematurely. The premature infant is especially vulnerable to this problem because the final stages of lung maturation in the fetus normally occur just prior to full-term birth. Hyaline membrane disease cannot be predicted before birth, and the mortality rate is low but significant.

This respiratory syndrome has been studied in newborn lambs, and the results show that in cases where pregnant ewes are subjected to stress and their lambs delivered prematurely, many of the lambs (75 percent) die soon after birth of respiratory distress similar to the hyaline membrane disease seen in human infants. When the fetal lambs are infused *in utero* with EGF for a few days prior to premature delivery, however, development of the lung epitheliums is accelerated, respiratory distress is infrequent, and almost all of the lambs survive. Moreover, in these same experiments, accelerated growth of epi-

A Science Education from A to Z

From the *ABC of Relativity* by Bertrand Russell, to Zeno's paradoxes, this 21-volume library provides a complete and fascinating science education.

Unlike an encyclopedia, this reference work is one you can read for pure enjoyment as well as refer to for reliable information. The key to this readability is the fact that THE REALM OF SCIENCE is actually a massive collection of selected writings arranged and indexed by subject. It is so complete, that the cumulative index alone runs almost 200 pages!

Think of a subject, look it up, and read what the world's foremost authorities have written about it.

The Greatest Minds the World Has to Offer

The authorities represented in this priceless collection read like a "Who's Who" in science. There's Priestley on the discovery of oxygen; Faraday on electrochemistry; E.O. Wilson on sociobiology; Ernst Nagel on Godel's proof. Plus Isaac Asimov, Jacob Bronowski, Martin Gardner, Max Planck, James Watson, George Gamow, Fritz Zwicky, and hundreds more. From ancient Babylonia to the present, you will be exposed to the greatest minds the world has to offer.

Einstein's special theory of relativity changed our concept of time, distance and mass.

A Valuable Research Tool

Although each volume contains its own index, the unique Science Concept Index "brings it all together." It will help you find vital information on a given subject, person, place or idea throughout the set. It will also enable you to trace various applications of a subject from one author to another, from one concept to another, or from one discipline to another. Imagine what a valuable research tool this can be. Taken as a whole, this 21-volume set provides an overview of science never before possible in a single work.

Keep Your Set Up-To-Date

To keep you informed of the latest scientific developments and to keep your 21-volume set up-to-date, you will also be entitled to receive—at your option—the fully illustrated REALM OF SCIENCE yearbook.

At an appropriate time, you will receive advance notification fully describing the upcoming yearbook and will have the option of refusing it if you wish. Barnes & Noble will guarantee the price of $9.95 (plus shipping and applicable taxes) for the first three years. However, you are under no obligation to ever buy a yearbook.

Act Now. . . Our Supply is Limited

THE REALM OF SCIENCE originally sold for $149.95. Until the supply lasts (We purchased the remaining inventory from the publisher), Barnes & Noble is offering the complete 21-volume set for only $39.95. That's about one-fourth of its original price. . . a discount of 73 percent!

Act now, and you won't be disappointed. (Each big 8" *x 10"* hardcovered volume contains almost 200 pages and is fully illustrated.) If you are not completely satisfied with the set, return it within 30 days and the purchase price will be refunded.

thelial tissue is noted not only in the lungs but also in other areas of the pulmonary epithelium, such as the trachea and esophagus.

An epithelial tissue in adults that appears to be very sensitive to EGF is the corneal epithelium in the eye. This tissue is important for sight and can be easily injured. Research has shown that in both experimental animals and in humans, EGF accelerates the proliferation of cells in a wounded area of the corneal epithelium, thereby hastening the wound-healing process. Because EGF is present in milk, a natural fluid, clinical trials are being conducted to determine whether milk might be a feasible treatment for corneal lesions. In fact, the use of EGF as a general wound-healing agent is being considered. In this regard, it is interesting to note that folk medicine often prescribes the application of urine to wounds. And in war situations this practice has been employed when other treatments were not immediately available. Urine is usually a sterile solution and contains high amounts of EGF.

Nature is often remarkably ingenious in devising strategies to maximize the utility of its products. In the case of protein molecules, it is not unusual for one protein to be capable of carrying out more than one distinct function. At the level of molecular architecture this is not a trivial engineering task. In addition to its capacity to stimulate cell growth and differentiation, the EGF molecule has a second biological activity. When administered to experimental animals and to humans, this hormone blocks the release of excess gastric acid induced by a variety of chemicals, such as histamine or pentagastrin.

The ability of EGF to control acid secretion in the stomach was discovered unexpectedly in 1975 when a British research group at Imperial Chemical Industries isolated and determined the structure of urogastrone—a protein hormone known since the 1920s to be present in high quantities in the urine of pregnant women and to be an inhibitor of acid secretion. Computer comparisons of urogastrone with other known proteins revealed that the primary structures (that is, the sequences of amino acids) of urogastrone and EGF are so nearly identical (within the limits of experimental technology) that one can conclude they are the same molecule. Thus milk-fed infants receive a hormone that may help to prevent discomforts and injuries to the stomach lining (ulcers, for example) resulting from excess gastric acid.

Scientists have been increasingly successful at removing selected cells from the intact animal and maintaining these cells in a growing state for long periods of time in the laboratory. This technique, called cell culture, involves placing the cells in a plastic dish with a defined medium of glucose, minerals, vitamins, and amino acids. Under these conditions the cells remain viable but do not grow. For growth and cell division to occur, serum—a blood fraction—is added to the medium. Serum apparently contains hormones, or growth factors, necessary to regulate cell growth and division and for many years has been considered to be indispensable for this purpose. Recent experiments, however, have shown that milk is also able to stimulate cell proliferation in cell culture and can make up for approximately 95 percent of the serum requirement. Biologically, this suggests that milk is a fluid rich in the factors that control cell growth, and EGF appears to be a key ingredient in milk for the stimulation of cell division. This has been demonstrated by treating milk with antibodies to EGF.

Antibodies are highly specific reagents that are able to recognize one particular protein molecule in a mixture of thousands of slightly different protein molecules. Antibodies bind to the protein they recognize and often inactivate it. When milk is treated with antibodies to EGF, the capacity of the milk to stimulate cell growth is reduced by 90 percent. This has been demonstrated in cell culture with human fibroblasts (connective tissue cells) and human glia cells (brain-derived cells). Different types of cells are known to vary in their responsiveness to any particular hormone; therefore, it is possible that milk may contain additional growth factors other than EGF that stimulate different cell types. For example, erythropoietin, a protein growth factor that controls the development of red cells in the blood, is known to be present in milk.

In summary, we know that EGF is able to exert a significant influence on the proliferation and differentiation of various types of epithelial cells in the intact animal. We also know that this hormone is present in physiologically significant quantities in milk. Is there a connection? Is milk a physiological vector for the delivery of important hormones to the infant? These intriguing questions will have to wait for further research before answers can be provided. To resolve some obvious questions, however, a few additional comments can be made at this time. If the hormone is ingested in milk and affects the growth and development of tissue in the gastrointestinal tract, it must be able to resist conditions in the gastrointestinal tract that cause the digestion of most protein molecules. Studies of the chemistry of EGF have shown that the hormone's activity is not destroyed by exposure to strong acid or proteases (enzymes that digest protein molecules). Therefore, it is not unreasonable to suggest that this growth factor may remain biologically active in the normally adverse conditions, for a protein molecule, of the gastrointestinal tract.

If EGF also affects other epithelial tissues, such as that of the lungs, then there is a second problem: the growth factor would have to be absorbed into the circulatory system by passing through the lining of the gastrointestinal tract. That this apparently can occur has been demonstrated in the experiments conducted with newborn mice. The results showed that oral administration, as well as subcutaneous injection, of EGF resulted in precocious eyelid opening, indicating that the hormone was absorbed from the gastrointestinal tract into the systemic circulation. This has not, however, been demonstrated with humans, and animal species differ in terms of which proteins will be absorbed.

As already mentioned, large numbers of babies in the United States are not fed with mother's milk but receive commercial formulas with either a soybean or bovine milk base. Does this make a difference as far as growth factors are concerned? Cells grown in culture can be stimulated to grow and divide by either human or bovine milk. When various commercial formulas were tested, however, none were able to stimulate cell proliferation. This is not to be taken as an indictment of the commercial formulas—certainly many children have been raised on formula without apparent adverse consequences. These results indicate that human milk is not duplicated by the industrial products and that our scientific technology is not always able to better or even equal nature.

What Color Is a Zebra?

Is it a white animal with black stripes? Or vice versa?

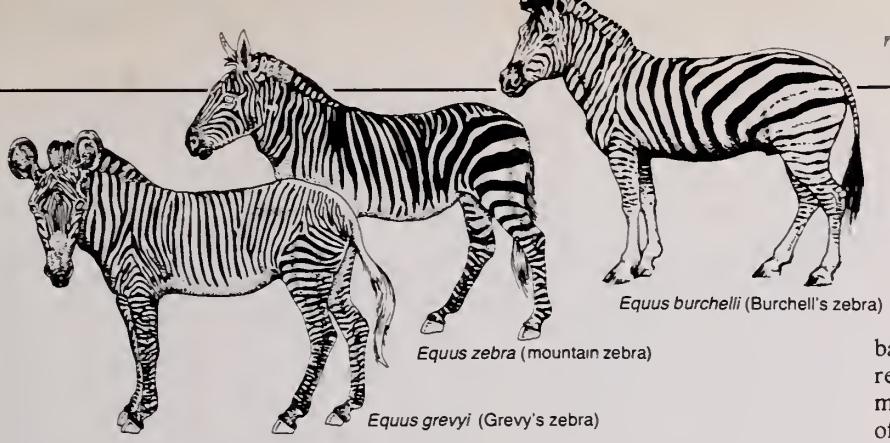
by Stephen Jay Gould

Some persistent, unanswered questions about nature possess a kind of majestic intractability. Does the universe have a beginning? How far does it extend? Others refuse to go away because they excite a pedestrian curiosity but seem calculated, in their very formulation, to arouse argument rather than inspire resolution. As a prototype for the second category, I nominate: Is a zebra a white animal with black stripes or a black animal with white stripes? I once learned that the zebra's white underbelly had decided the question in favor of black stripes on a blanched torso. But, to illustrate once again that "facts" cannot be divorced from cultural contexts, I discovered recently that most African peoples regard zebras as black animals with white stripes.

In a poem about monkeys, Marianne Moore discussed some compatriots at the zoo and contrasted elephants and their "strictly practical appendages" with zebras "supreme in their abnormality." Yet we learned last month that the three species of zebras may not form a group of closest relatives—and that stripes either evolved more than once or represent an ancestral pattern in the progenitors of true horses and zebras. If stripes are not the markers of a few related oddballs but a basic pattern within a large group of animals, then the problems of their construction and meaning acquire more general interest. J. B.L. Bard, an embryologist from Edinburgh, has recently analyzed zebra stripes in the broad context of models for color in all mammals. He detected a developmental unity underlying the different patterns of adult striping among our three species of zebras and, *inter alia,* even proposed an answer to the great black-and-white issue in favor of the African viewpoint.

Biologists follow a number of intellectual styles. Some delight in diversity for its own sake and spend a lifetime describing intricate variations on common themes. Others strive to discover an underlying unity behind the differences that sort these few common themes into more than a million species. Among searchers for unity, the Scottish biologist and classical scholar D'Arcy Wentworth Thompson (1860–1948) occupies a special place. D'Arcy Thompson spent his life outside the mainstream, pursuing his own brand of Platonism and packing insights into his thousand-page classic *On Growth and Form*—a book so broad in appeal that it won him an honorary degree at Oxford and, thirty years later, entered the *Whole Earth Catalog* as "a paradigm classic."

D'Arcy Thompson struggled to reduce diverse expressions to common generating patterns. He believed that the common patterns themselves had a kind of Platonic immutability as ideal designs, and that organisms played with constrained variations upon them. He developed a theory of "transformed coordinates" to depict variations as expressions of a single pattern, stretched and distorted in various ways. But he worked before computing machines could express such transformations in numerical terms, and his theory achieved little impact because it never progressed much beyond the production of pretty pictures.



As a subtle thinker, D'Arcy Thompson understood that emphases on diversity and unity do not represent different theories of biology, but different aesthetic styles that profoundly influence the practice of science. No student of diversity denies that common generating patterns exist, and no searcher for unity fails to appreciate the uniqueness of particular expressions. But allegiance to one or the other style dictates, often subtly, how biologists view organisms and what they choose to study. We must reverse the maxim of the reprobate father teaching his son morality—do what I say, not what I do—and recognize that biological allegiances lie not so much in words but in actions and subjects chosen for research. Note what I do, not what I say. Of the "pure taxonomist"—the describer of diversity—D'Arcy Thompson wrote:

> When comparing one organism with another, he describes the differences between them point by point and "character" by "character." If he is from time to time constrained to admit the existence of "correlation" between characters . . . he recognizes this fact of correlation somewhat vaguely, as a phenomenon due to causes which, except in rare instances, he can hardly hope to trace; and he falls readily into the habit of thinking and talking of evolution as though it had proceeded on the lines of his own description, point by point and character by character.

D'Arcy Thompson recognized, with sadness, that the theme of underlying unity had received much lip service, but little application. Differences between the striping patterns of our three zebra species had been described minutely and much energy had been invested in speculations about the adaptive significance of differences. But few had asked whether all the patterns might be reduced to a single system of generating forces. And few seemed to sense what significance such a proof of unity might possess for the science of organic form.

The vulgar version of Darwinism (not Darwin's) holds that natural selection is so powerful and pervasive in scrutinizing every variation and constructing optimal designs that organisms become collections of perfect parts, each minutely crafted for its special role. While not denying correlation in development or underlying unity in design, the vulgar Darwinian does relegate these concepts to unimportance because natural selection can always break a correlation or remold an inherited design.

The pure vulgar Darwinian may be a fiction; no one could be quite so foolish. But evolutionary biologists have often slipped into the practice of vulgar Darwinism (while denying its precepts) by following the reductionistic research strategy of analyzing organisms part by part and invoking natural selection as a preferred explanation for all forms and functions—the point of D'Arcy Thompson's profound statement cited above. Only in this way can I make sense of the curious fact that unity of design has received so little attention in the practice of research—although

AMNH

much lip service in textbooks—during the past forty years, while evolutionary biologists have generally preferred a rather strict construction of Darwinism in their explanations of nature.

For many reasons, ranging from the probable neutrality of much genetic variation to the nonadaptive nature of many evolutionary trends, this strict construction is breaking down, and themes of unity are receiving renewed attention. Old ideas are being rediscovered; D'Arcy Thompson, although never out of print, is now often out of bookstores (and in personal libraries). One old and promising theme emphasizes the correlated effects of changes in the timing of events in embryonic development. A small change in timing, perhaps the result of a minor genetic modification, may have profound effects on a suite of adult characters if the change occurs early in embryology and its effects accumulate thereafter.

The theory of human neoteny, often discussed in these columns, is an expression of this theme. It holds that a slowdown in maturation and rates of development has led to the expression in adult humans of a large suite of features generally found in embryos or juvenile stages of other primates. Not all these features need be viewed as direct adaptations built by natural selection. Many, like the "embryonic" distribution of body hair on heads, armpits, and pubic regions or the preservation of an embryonic membrane, the hymen, through puberty, may be nonadaptive consequences of a basic neoteny that is adaptive for other reasons—the value of slow maturation in a learning animal, for example.

Bard's proposal for "a unity underlying the different zebra striping patterns" (*Journal of Zoology,* London, vol. 183, 1977, pp. 527–39) follows D'Arcy Thompson's theme of a basic pattern stretched and pulled in different ways by varying forces of embryonic growth. These varying forces arise because the basic pattern develops at *different times* in the embryology of the three species. Bard thus combines the theme of transformed coordinates with the insight that substantial evolution can proceed by changes in the timing of development.

The basic pattern is simplicity itself: a series of parallel stripes deposited perpendicular to a line running along the embryonic zebra's back from head to tail—hang a sheet over a taut wire and paint vertical stripes on each side of it. These stripes are initially laid down at a constant size, no matter how big the embryo that forms them. They are 0.4 mm, or approximately 20 cell diameters, apart. The bigger the embryo, the greater the initial number of stripes. (I should point out that Bard's argument is a provocative model for testing, not a set of observations; no one has ever traced the embryology of zebra striping directly.)

The three zebra species differ in both number and configuration of stripes. In Bard's hypothesis, these complex variations arise only because the same basic pattern—the parallel stripes of constant spacing—develops during the fifth week of embryonic growth in one species, during the fourth week in another, and during the third week in the third species. Since the embryo undergoes complex changes in form during these weeks, the basic pattern is stretched and distorted in varying ways in the three species, leading to all the major differences in adult striping.

The three species differ most notably in patterns of striping on the rump and hind quarters. The Grevy's zebra (*Equus grevyi*) has numerous fine and basically parallel stripes in these rear regions. On Bard's model, the stripes must have formed when the back part of the embryo was relatively large. (The larger the part, the more stripes it receives, since stripes are initially formed at constant size and spacing.) In the embryology of horses, the tail and hind regions expand markedly during the fifth week *in utero.* If adults possess numerous, fine posterior stripes, they must form after this embryonic expansion of the rear quarters. (Unfortunately, no one has ever studied the early embryology of zebras directly, and Bard assumes that the intrauterine growth patterns of true horses are followed by their striped relatives as well. Since basic features of early embryology tend to be so conservative in evolution, true horses are probably fair models for zebras.)

The mountain zebra, *Equus zebra,* looks much like *E. grevyi* until we reach the haunch, where three broad stripes substitute for the numerous fine stripes of Grevy's zebra. Broad stripes on adults indicate initial formation on a small piece of embryo (where few stripes could fit), and later rapid growth of the piece (widening the stripes as the general area expands). If an embryo forms stripes in its fourth week, just before the posterior expansion that provides room for the many fine marks of Grevy's zebra, it will build the pattern of a mountain zebra during later embryonic growth.

Burchell's zebra, *Equus burchelli,* also has just a few broad stripes on its haunch. But, while the mountain zebra has fine stripes over most of its back and broad stripes only over the haunch, the broad stripes of Burchell's zebra begin in the middle of the belly and sweep back over the haunch. This pattern suggests an initial formation of stripes during the third week of embryonic growth. At this early stage, the embryo has a short, compact back, which later expands toward the rear in a broad, arching curve while the belly remains short. A stripe that initially ran vertically from spine to belly would be

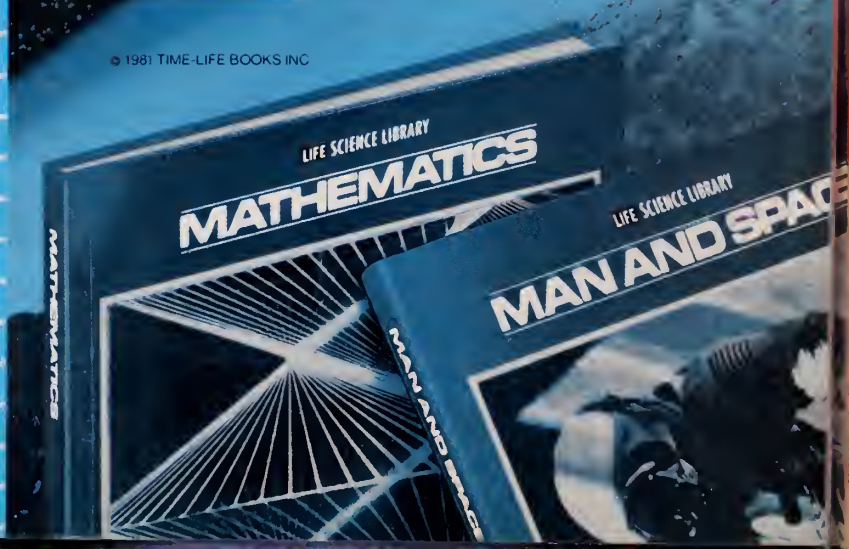
Share the excitement of today's science with your family and prepare them for the technological marvels of the world they'll live in. The brand-new Revised Edition of the famous LIFE SCIENCE LIBRARY explains it all—from lasers that monitor minuscule changes in the shape of the earth to that incredible assembly of pumps, levers, energy converters and electrical circuits, the human body.

Did you learn about science from the original LIFE SCIENCE LIBRARY? Your family will find the same depth of authority in the Revised Edition. The same clarity. The familiar simplicity with which TIME-LIFE BOOKS explains complex ideas. The Mind... Energy... Drugs... The Body... Man and Space—each volume combines dazzling pictures and straightforward text to tell its story. And every volume in the Revised Edition reveals the latest developments, the current research, the theories that lie behind tomorrow's discoveries.

See for yourself—no obligation to buy.

Look through the introductory volume—The Mind for 10 days as our guest. Enjoy its intriguing exploration of the way you think...of what happens when you sleep...what pain really is...why you are using only the back part of your brain to read these words. This big, 200-page volume explains current knowledge on dreams, mental disorders, mind-expanding drugs, biofeedback. You can even experiment with baffling illusions that reveal how much—or how little—we know about what we see.



Begin a revealing adventure in the pages of The Mind. Simply mail the reply card today.

TIME LIFE BOOKS

pulled toward the rear as the embryo's top surface expanded backward while its belly grew little. An adult stripe, subject to such deformation in its embryonic life, would be broad and would run from the belly up and over the haunch—as in Burchell's zebra.

Thus, Bard can explain differences in rear striping of the three species as the results of deforming the same initial pattern at different times during normal embryonic growth. His hypothesis receives striking support from another source: the total number of stripes itself. Remember that Bard assumes a common size and spacing for stripes at the outset. Thus, the larger the embryo when stripes first form, the greater the number of stripes. Grevy's zebra, presumably forming its stripes as an embryo of five weeks and about 32 mm, has 80 or so stripes as an adult—or about 0.4 mm per stripe. Mountain zebras with a fourth-week embryo of some 14 to 19 mm in length have about 43 stripes—again about 0.4 mm per stripe. Burchell's zebra has 25 to 30 stripes; if they form in a third-week embryo some 11 mm long, we get the same value—about 0.4 mm per stripe.

As additional support, and a lovely example of the difference between superficial appearance and knowledge of underlying causes, consider an old paradox involving hybrid offspring between zebras and true horses. These animals almost always have more stripes than their zebra parent. "Common sense," based on superficial appearance, declares this result puzzling. After all, the state in between stripes and no stripes is few stripes. But if Bard is right about the underlying causes of striping, then this paradoxical result makes sense. The intermediate state between stripes and no stripes might well be a *delay* in the embryonic formation of stripes. If stripes then form at their common size and spacing upon a larger embryo, the resultant adult will have *more* stripes.

"Transformed coordinates" on the carapaces of crabs from two different genera demonstrate unity of form.

From *On Growth and Form*, by D'Arcy Wentworth Thompson/Cambridge University Press, 1917

If a unity of basic architecture underlies the diversity of zebra striping, then we must suspect that we are confronting a general pattern in nature, not just the "supreme abnormality" that Marianne Moore described. Darwin viewed horses in this light and recognized that the capacity for striping in all horses constituted a powerful argument for evolution itself. (As in last month's column, I use *horse* as a general term for all members of the family Equidae—true horses, asses, and zebras. When I wish to indicate Old Dobbin alone, I will speak of *true horses*.) If zebras are odd and perfect adaptations for camouflage, God might have made them as we find them. But if zebras merely actuate and exaggerate a potential property of all horses, then the occasional realization of striping in other horses—where it cannot be viewed as a perfected adaptation ordained by God—must indicate a community of evolutionary descent.

Darwin devoted much space in chapter 5 of the *Origin of Species* to an exhaustive tabulation of occasional striping in other horses. Asses, he found, often have "very distinct transverse bars . . . like those on the legs of a zebra." True horses often possess a spinal stripe, and some also have transverse leg bars. Darwin found a Welsh pony with three parallel stripes on each shoulder. And he noted that hybrids (with no zebra parents) were often strongly striped—an example of the common, and still mysterious, observation that hybrids often display ancestral reminiscences present in neither parent. "I once saw a mule," Darwin wrote, "with its legs so much striped that any one at first would have thought that it must have been the product of a zebra."

From this illustration of common, and often nonadaptive, patterns in all horses, Darwin drew one of his most powerful and passionate arguments for evolution—well worth quoting *in extenso:*

> He who believes that each equine species was independently created, will, I presume, assert that each species has been created with a tendency to vary, both under nature and under domestication, in this particular manner, so as often to become striped like other species of the genus; and that each has been created with a strong tendency, when crossed with species inhabiting distant quarters of the world, to produce hybrids resembling in their stripes, not their own parents, but other species of the genus. To admit this view is, as it seems to me, to reject a real for an unreal, or at least for an unknown, cause. It makes the works of God a mere mockery and deception; I would almost as soon believe with the old and ignorant cosmogonists, that fossil shells had never lived, but had been created in stone so as to mock the shells now living on the seashore.

The same theme also suggests an answer to the title of last month's essay: "What, if Anything, Is a Zebra?" I advanced the argument that zebras may not form a group of closest relatives, but a set of different horses that had either evolved stripes independently or inherited them from a common ancestor (while asses and true horses lost them). Bard's hypothesis lends support to this conjecture because it suggests that the underlying pattern of zebra striping may be so simple that all horses include it in their repertoire of development. Zebras, then, may be the realization of a potential possessed by all horses.

Finally, moving from the sublime to the merely interesting, Bard proposes a solution to the primal dilemma and argues that zebras are black animals with white stripes after all. The white underbelly, he points out, is a lousy argument because many fully colored mammals are white underneath. Color may be generally inhibited in this region for reasons at present unknown. Mammals do not have their colors painted on a white background. The basic issue may then be rephrased: Does striping result from an inhibition or a deposition of melanin? If the first, zebras are black animals; if the second, they are white with black stripes.

Biologists often look to teratologies, or abnormalities of development, to solve such issues. Bard has uncovered an abnormal zebra whose "stripes" consist of rows of dots and discontinuous blotches, rather than coherent lines of color. The dots and blotches are white on a black background. Bard writes: "It is only possible to understand this pattern if the white stripes had failed to form properly and that therefore the 'default' color is black. The role of the striping mechanism is thus to inhibit natural pigment formation rather than to stimulate it." The zebra, in other words, is a black animal with white stripes.

Stephen Jay Gould teaches biology, geology, and the history of science at Harvard University.

Come share Costa Rica. From an active volcano to the friendly people.

Now 50% more for your dollar.

Peaceful Costa Rica is truly a country of contrasts. You can have the unforgettable experience of standing next to an active volcano. Yet there's no experience quite like the gentle hospitality of Costa Rica's friendly people.

Spend a day driving through beautiful alpine scenery to the very edge of the crater of Irazu Volcano. Then return to San Jose by way of Cartago, the old capital founded by the Spanish in 1564.

And during your stay in San Jose, mingle with the friendly people at their local markets and fiestas as well as at your own hotel. You're sure to appreciate the gentle hospitality that's hard to find anywhere else.

Four nights accommodations, a visit to Irazu Volcano and a city tour of San Jose start as low as $87 (ITOEA1HDCR) per person double occupancy plus air fare. And with Costa Rica's favorable exchange rate, now you get 50% more for your dollar.

For more information on Costa Rica, call your travel agent or write: COSTA RICA TOURIST BOARD, Box E12, 3709 N. W. 36th St., Miami, Florida 33142.

The Elusive Eureka

A puzzling fossil provides a lesson in the scientific method

by Niles Eldredge

The tendency of scientists to make pronouncements from remote Olympian heights lends credence to the charge that science is just another belief system, no different from any other. The current efforts of fundamentalist Christians to inject the biblical story of Creation into biology curricula across the nation exploit this very impression. Creationist cries of "equal time" appeal to people's sense of fair play because science, like religion, often appears authoritarian. And it is true that science has become so complex that no one can hope to grasp it all. Most of us are content to believe that the earth is round, even though we are personally unable to make the necessary observations that verify it. But before a scientific idea can earn this kind of routine acceptance, it must be subjected to the scrutiny of the "scientific method."

The scientific method is not some mysterious form of higher cerebration. Its principle is simply that our ideas about the universe—how it is constructed, how it came to be—must conform to our observations. Scientists test an idea by predicting what they should find if it is true, and their understanding of the natural world is refined in a constant interplay of ideas and observations. This very human exercise is very different from the unquestioning acceptance of "revealed truth." A scientist is prepared to evaluate any new piece of evidence, even if it challenges an orthodox theory. Sometimes the theory will be discarded or modified; sometimes the evidence will be thrown out of court. But in either case something will have been gained. I have here a modest example of how the system works; perhaps it will give an idea of what scientists actually do for a living.

No one (presumably) would dare write an article for a science magazine without being reasonably sure of his or her ground. So when I reported in the July 1980 issue of *Natural History* on distribution patterns of Devonian trilobites in the Southern Hemisphere, I was relying on 150 years of accumulated paleontological research, as well as ten years of my own contemplation of these fossils. The picture I presented was a neat one. Trilobites are extinct relatives of crabs and shrimps; those that I wrote about lived in what was evidently a cold-water habitat during the Devonian period, 395 to 345 million years ago. Their fossils are most numerous in Andean South America from southern Peru south through Bolivia and Argentina. They also occur in less exuberant numbers in the Amazon Basin, portions of southern Brazil and Uruguay, the Falkland Islands, and South Africa. The most reasonable explanation for this distribution is that there once was a great, partly submerged landmass, which geologists call Gondwana, that broke up to form South America, Antarctica, Africa, India, and Australia. The widely scattered localities that yield these cold-water Devonian fossils were once much closer together, and all were south of 60° south latitude.

As the article for *Natural History* was in its final editorial phase, however, I received a letter from Alfonso Segura Paguaga, a Central American geologist living in Esparza, a rural area of Costa Rica near the Pacific coast city of Puntarenas. I was startled at his announcement of the discovery of a Devonian trilobite in Costa Rica. No rocks even remotely as old had ever been found there. Paguaga wanted me to examine the specimen, proposing to name it *Phacops esparsocostariccensis.* I hurriedly wrote back that I would be delighted to work on the trilobite, the possibility of a bona fide discovery lurking in the back of my mind.

Paguaga arrived in my office with the trilobite, as well as fossils from four separate outcrops in the environs of Esparza. Eagerly unwrapping the trilobite first, I was flabbergasted. There before me lay a typical example of *Metacryphaeus tuberculatus*—a very common trilobite, indeed, but one known only from southern Peru and Bolivia. "Were I not informed," I wrote rather formally in my report to Paguaga, "that the specimen came from Costa Rica, I would without hesitation say it came from the region of Padilla, Bolivia."

Two things were puzzling about the fossil. The first was its age: as far as I knew, Venezuela and Colombia in South America, and Mexico in North America, were the closest places to Costa Rica that had ever produced a Devonian trilobite. Second, the specimen was not the type of trilobite we would expect to find even in those areas. Trilobites from northern South America are of the same basic stripe as our own Northern Hemisphere Appalachian trilobites—and radically different from those, such as *Metacryphaeus,* that lived in the cold seas that bathed Gondwana.

The geologic history of Central America and the Caribbean is extremely complex and as yet only partly unraveled. What we seemed to have was

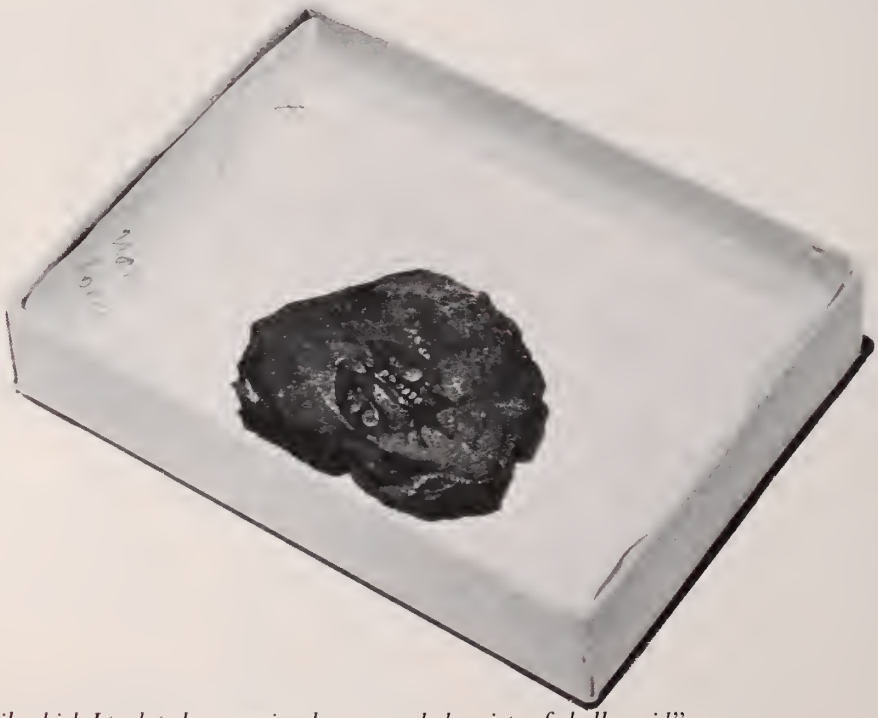
an "island" of Devonian Gondwana—a portion of Andean South America that had somehow become detached and incorporated as an exotic chunk into what later became Costa Rica. A radically new view of shifting fragments of continental plates colliding to form portions of Central America started to take shape in my mind. It was too late to stop the *Natural History* presses, but I began to envision a quick report to *Science* or some other prestigious "what's the latest development in science" journal.

But there was a small fly in the ointment. Paguaga said he got the trilobite from a small boy who had brought it to school. The boy had found it on a local roadside. If we were to tell the world of an exotic Devonian "island," we had to be able to point to a mass of rock and say, "There it is." Another specimen Paguaga brought with him seemed promising: a chunk of brown siltstone about the size of a silver dollar. It had shell fragments that looked the right age on one side, and a gorgeous fossil, which I took to be a previously unrecorded variety of phyllocarid, a type of crustacean especially well known in Devonian rocks. About an inch long, the symmetrical structure was elaborately sculptured with a variety of bumps and furrows reminiscent of, although a bit more complicated than, the carapaces of known phyllocarids. We seemed to be in good shape, but Paguaga understood the necessity for ironclad evidence that the trilobite was indeed a native of Esparza.

Shortly after his return home, Paguaga went to work, and I was soon bombarded with packages of Costa Rican fossils. Concentrating on the outcrop that had produced the crustacean, he found more than fifty complete fossils and shipped them all to New York. To my chagrin, all proved to be clams and snails no older than twenty or thirty million years—very much the sort of thing one was supposed to find in Costa Rica.



With my doubts deepening, I retrieved the "crustacean" from the collection of Costa Rican fossils, stared at it hard, and realized it was not a phyllocarid after all. It was (and I am no botanist) apparently some sort of nut or seed pod. Groaning, I realized my enthusiasm had carried me away. I had fantasized a Tertiary fruit into a Devonian crustacean! All of a sudden I was quite glad I hadn't batted out a note to *Science* trumpeting our wonderful discovery.

The real story of the Esparza trilobite is not exactly fraught with scientific significance. It turned out my first suspicion about the origin of the fossil was right. An American, leaving La Paz, Bolivia, to live in Costa Rica, bought the trilobite from an "old Indian" as a souvenir. (I hear that these trilobites have been for sale all over La Paz in recent years.) He had a minor car accident on a Costa Rican road one day, and the trilobite was lost—only to be found by the little boy. All the details were uncovered by Paguaga—a dogged truth seeker if ever there was one—who advertised in the papers and tracked down the American, still living in Costa Rica. Of the thousands of Andean fossils in my office, none has taken a more circuitous route from the mountains of Bolivia to our labs in New York.

The whole episode, as absurd as it may seem, really does show how science works. The misplaced trilobite challenged several longstanding notions I had confidently recounted in my article for *Natural History.* Either the ideas or the trilobite had to give.

In the end, I was sorry not to have been a party to a real discovery. It would have been nice to have had the chance to exclaim "Eureka!" the way scientists are popularly supposed to do. You know the image. After years of tedious measurement, a new generalization on the properties of matter suddenly dawns on the patient physicist; after much careful planning, the pith-helmeted coot in khaki shorts bags a "hitherto-unknown-to-science" butterfly in the depths of Amazonia. Eureka! But, alas, eurekas are damn hard to come by. The true stuff of science remains the sure and steady checking of ideas against worldly realities.

Niles Eldredge is a curator in the Department of Invertebrates at the American Museum of Natural History.

". . . a gorgeous fossil, which I took to be a previously unrecorded variety of phyllocarid"

The Onkyo TX-4000.
It will tame you, thrill you, tantalize and transport you.

The Onkyo TX-4000 Quartz Synthesized Tuner/Amplifier is one of the most perfect stereo receivers we've ever designed. Nothing else in its price range provides the brilliant purity, dynamic headroom, and full excitement of its sound.

The Onkyo TX-4000 brings tuning accuracy to a new level of precision . . . with an advanced approach to quartz-synthesized digital tuning. And the amplifier section provides all the dynamic headroom demanded by today's audiophile recording techniques. Onkyo's exclusive Dual-Super-Servo system makes it possible, by allowing the power supply to perform as if it were 50-times larger. And there's more . . . LED power metering, memory to pre-set 6 AM and 6 FM stations . . . and elegant styling with a flip-down control panel.

All combine to make The Onkyo TX-4000 a tuner/amplifier you will definitely want to audition . . . and then own. Hear it now at your Onkyo dealer.

Debut of an Interstellar Bubble

A new, fourth type of emission nebula is found

by Stephen P. Maran

The Rosette nebula is a beautiful glowing gas cloud that surrounds a cluster of young hot stars in the constellation Monoceros, about 5,200 light-years from the earth. It has long puzzled astronomers, but a consensus has now been reached: the Rosette is a large interstellar bubble.

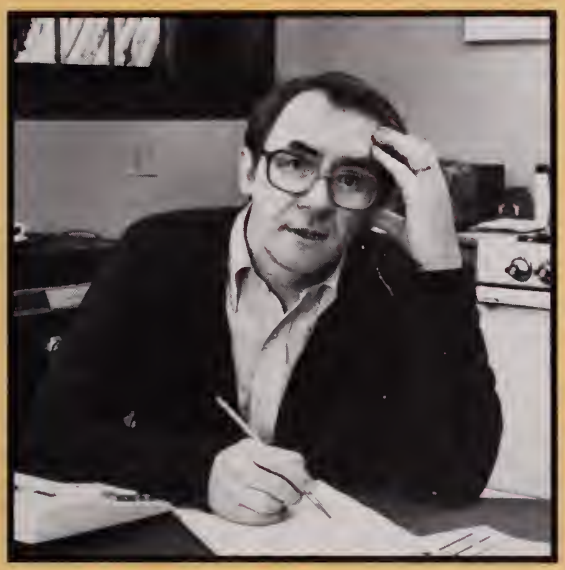
The term *interstellar bubble* was itself invented only six years ago, a decade after the first suggestion that such objects might exist. It refers to a type of emission nebula characterized by a low-density cavity formed by winds from one or more stars that push away the surrounding interstellar gas. The displaced gas forms a thick shell around the cavity, like the piles of snow at the side of a freshly plowed road.

Emission nebulae are clouds of cosmic gas that shine by their own light, rather than by reflecting the light of stars. Until now, they were classified into three types: H II regions, planetary nebulae, and remnants. H II regions consist of interstellar gas that is heated and made to glow by the ultraviolet rays from adjacent large hot stars. The Orion nebula (*Natural History,* May 1980) is a good example. Planetary nebulae, such as the Ring nebula in Lyra, are formed from the outer layers of red giant stars. After the layers are ejected, only the small blue cores of the once grossly extended giants remain. Remnants consist of rapidly expanding material from exploding stars (novae and supernovae). The Crab nebula is the best-known supernova remnant.

Interstellar bubbles, now recognized as a fourth type of emission nebula, are like H II regions and planetary nebulae in that they shine because the stars within them stimulate them with ultraviolet light. However, this type of emission nebula differs from the other types in being shaped by the winds from those stars.

The recognition of interstellar bubbles as a distinct type of nebula can be traced back to an investigation of the Rosette nebula by the radio astronomer T. K. Menon at Green Bank, West Virginia, in 1961. He mapped the Rosette with an 85-foot radio telescope of the National Radio Astronomy Observatory at Green Bank. Although Menon did not himself develop the theory of interstellar bubbles, his map was the first of several clues that eventually led astrophysicists to identify this new type of nebula.

At the time of Menon's study, the Rosette nebula was classified as an H II region. In fact, a photograph of the nebula was used to illustrate the concept of an H II region in a college astronomy textbook published in the same year that Menon mapped the Rosette. The caption for the photograph did not mention the striking difference between the Rosette and other H II regions such as the Orion nebula, although the difference was readily apparent. The Rosette nebula seems to have a relatively darker central region, surrounded by a brighter zone, whereas the Orion nebula has a bright center.



Menon wished to explore the nature of the dark central region in the Rosette nebula. Telescopic photographs record nebular light that is produced by gas with temperatures of about 4,000° to 10,000°C. The "hole" seen in photographs of the Rosette might be due, Menon reasoned, either to a substantial deficiency of gas or to the presence of gas just as dense as that found in the bright rim of the nebula but at a much higher temperature. Nebular gas of a few hundred thousand degrees or hotter would not glow noticeably in visible light but would emit strong radio waves. Thus, if the radio map of the Rosette were to show a bright central region, the presence of much superhot gas would be indicated, but if the map showed a dim hole, like that in the telescopic photographs, a deficiency of gas would be confirmed. A third possibility, that the apparent hole might be due to a cloud of dark interstellar dust, is ruled out because the star cluster at the center of the Rosette is plainly visible on the photographs.

After scanning the Rosette nebula with the 85-foot Green Bank radio telescope, Menon presented the results in the form of a contour map of radio-brightness levels that resembles a geographer's contour map of terrain altitudes. At the center of the series of closed solid curves on this map, there appears a small, dashed loop. The dashes indicate a dip in the middle of the nebula, rather than a peak in radio brightness. Thus there is indeed a deficiency of gas in the center of the Rosette. The observations were incapable of determining just how hot and thin the residual gas in the aforementioned hole seen in the photographs might be.

Subsequent observations made with

Some people feel...

"My house was robbed. My neighbor says I should 'pad' my insurance claim. Why should I have to lie to come out even?"

That's why we want you to know...

You don't have to lie to come out even. Your neighbor, like some homeowners, may be confused about what homeowners insurance actually provides for loss of contents. Some think it guarantees "replacement value." In fact, most homeowners insurance policies provide "cash value."

There is an important difference. "Replacement value" means the actual cost to replace—brand new—the stolen item. "Cash value" means the current *depreciated* amount the item was worth *at the time of* the loss.

For example, if your stereo is stolen, a standard homeowners policy would give you the "cash value." Assume you paid $1,000 for the stereo ten years ago; today it may be worth $500. So you would get $500 from your insurance company, minus the deductible you have selected.

Policies are available that offer "replacement value" or "agreed value." But, of course, these kinds of coverage are more expensive than the conventional homeowners policy. Which kind of coverage is right for you? Most people opt for the conventional homeowners policy. In the event of a major disaster, like a fire or a windstorm, it enables you to put your home together again. And in the event of a burglary, it will give you the fair "cash value" of the item you lost.

For more information, consult your insurance agent. Review your present coverage and ask about the kind of protection you feel you need. Determine costs. Check to see if your standard homeowners policy provides limited coverage on items such as paintings, prints, cameras, jewelry, silverware, or furs. If so, you may want additional coverage, or "floaters," for those valuables.

A frank talk with your agent can prevent surprises and create a better understanding of what you can reasonably expect from your insurance policy when you have a claim.

We're working to keep insurance affordable.

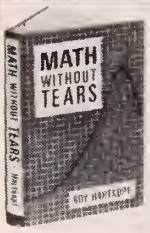
WHICH EXERCISER PROVIDES THE MOST IDEAL C.V. EXERCISE ?

Exercise Bike ☐
Treadmill ☐
Nordic Track ☑

NordicTrack

Jarless, Total-Body Cardiovascular Exerciser



Duplicates XC Skiing for the best motion in fitness.

Better than treadmills . . . No body-damaging, jarring motion. Doesn't neglect the arms and shoulders. NordicTrack is smaller, lighter, more portable, doesn't require motors and is very quiet.

Better than bikes . . . Stand-up position provides far more uniform leg muscle loading. Makes high heart rates easier to attain. Arms and shoulders exercised just as effectively as the legs. More muscle mass involved. Adjustable arm and leg resistance.

a more advanced radio telescope confirmed Menon's findings, and we now know that the Rosette nebula consists of a central cavity almost seventy light-years in diameter surrounded by a bright, roughly spherical shell of gas, about twenty-three light-years thick and containing enough material to make over 11,000 suns. The nebula has attracted the attention of many astronomers since Menon's study, and a variety of ideas have been proposed to explain its unusual form.

The first of these ideas was that as the young stars at the heart of the nebula were formed, their ultraviolet radiation began traveling out through the surrounding gas, heating and ionizing it and also producing a shock wave that pushed the gas outward. Mathematical analysis, however, soon showed that any such shock wave would be too weak to produce a cavity of the observed proportions.

Two other theories, which appeared to be based on sounder principles, were proposed in 1966 by William G. Mathews, a young postdoctoral fellow at the Mount Wilson and Palomar Observatories in Pasadena, California. One theory he advanced was the idea that the hole in the Rosette nebula had resulted from the formation of the star cluster in its center. In other words, according to this "cavitation" theory, the missing gas had condensed to form the observed stars. Mathews's second theory, now recognized as the first proposal for the existence of interstellar bubbles, was that the hottest stars in the Rosette cluster have powerful, high-temperature stellar winds, which sweep away the surrounding gas, thus producing the hole.

One point that favors the cavitation theory is that the amount of missing gas (which can be estimated by assuming that the hole in the Rosette nebula was once filled by gas as dense as that now found in its bright rim) is about equal to the total mass of the stars in the cluster at the nebula's center. Since nature abhors a vacuum, the cavitation theory predicts that the gas in the rim is now pouring into the hole. Specifically, an inflow of gas at a velocity higher than the speed of sound (about six miles per second in the nebula as compared with one-fifth of a mile per second on Earth) is predicted.

Mathews's second theory, which ascribes the hole in the Rosette nebula to the action of hot stellar winds, has been updated by several other astrophysicists. In its revised form, the wind theory predicts that the bright gas on the rim of the hole is flowing outward at a speed above the speed of sound. According to this theory, since the hole is filled by outward-blowing winds, it is also predicted that the thin gas in the hole is at a temperature of about 500,000°C.

At the time his first two theories were proposed, Mathews recognized that both of them invoked processes not actually known to occur. There were no other known cases of holes formed in nebulae as a result of the condensation of stars nor were stars of the type found in the center of the Rosette nebula known to possess powerful stellar winds. In 1967, these uncertainties led Mathews to propose a third theory.

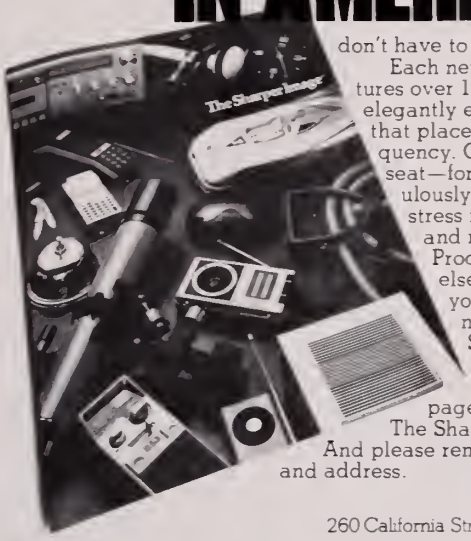
According to this theory, the central region of the Rosette nebula was originally filled by a mixture of gas and microscopic particles of interstellar dust. Such dust is found, for example, mixed in with the shining gases of the Orion nebula. Mathews proposed that the dust was electrified by ultraviolet light from the centrally located stars and that it was pushed outward from the center of the nebula by the pressure of light from the newly formed stars in the cluster. This process would be analogous to the formation of the dust tail of a comet, which occurs when sunlight pushes tiny dust particles away from the head of the comet. The outward-moving dust of the Rosette would then in effect drag the adjacent gas outward with it, accounting for the formation of the central hole. This theory predicts that the gas on the rim of the hole is flowing outward, as in the wind theory, but at less than the speed of sound.

In summary, two of Mathews's theories predict outward flow although they differ from each other in whether the flow is subsonic or supersonic. Mathews's other theory predicts supersonic inward flow. Thus no two theories agree on both the direction and the speed of the gas flow, and so observational tests should be possible. This circumstance inspired numerous observations including those of astronomers at the Cerro Tololo Inter-American Observatory in La Serena, Chile; the Marshall Space Flight Center in Huntsville, Alabama; the University of Manchester in England; and the Algonquin Radio Observatory in Ottawa, Canada.

These many studies of the Rosette nebula came to a common conclusion. Speeds well above the six miles per second velocity of sound were observed in the nebula. Hence the one theory that

involves subsonic flow, Mathews's third proposal in 1967 that the cavity was produced by the pressure of starlight, has been eliminated.

You might think it an elementary matter to determine whether the supersonic flow in the Rosette is directed inward or outward, but such is not the case. The velocity is determined by measuring the Doppler shifts of spectral lines. Due to the Doppler effect, gas moving away from the earth emits lines that are red-shifted, while gas approaching the earth emits blue-shifted lines. The size of the Doppler shifts observed in the spectrum of the Rosette nebula tells us that the flow is supersonic. If the nebular gas were flowing outward, then gas on the near side of the nebula would produce blue-shifted lines; if the gas were flowing inward, then blue-shifted lines would come from the gas on the far side. But since the nebula is transparent and light from both its near side and far side is recorded simultaneously with a spectrograph, when we find a blue-shifted line, we do not know whether it comes from the front or the back of the Rosette. We know how *fast* the gas is going, but not which *way* it is going.



One team of astronomers found indications that the flow in the Rosette is inward, as predicted by the cavitation theory, but this result is not very persuasive. A more conclusive finding comes from studies with the International Ultraviolet Explorer (IUE) satellite. These observations show that the two brightest stars in the Rosette nebula actually do have strong stellar winds.

According to Peter Conti, an expert on stellar winds and interstellar bubbles at the University of Colorado in Boulder, the brightest star in the Rosette has more than fifty times the mass of the sun and is nearly a million times brighter. Its wind alone may have been sufficient to blow out the large cavity we now observe in the nebula.

A final test, now being carried out with the IUE, is attempting to measure the temperature of the gas in the hole of the Rosette. If, as the wind theory predicts, this thin gas has a temperature of about 500,000°C, then our recently formed conviction that the Rosette nebula is an interstellar bubble will be vindicated.

Stephen P. Maran is a senior staff scientist in the Laboratory for Astronomy and Solar Physics at NASA's Goddard Space Flight Center in Greenbelt, Maryland.

Volcanoes and the Maya

In A.D. 260, a catastrophic eruption drove the southeastern Maya from their lands in what is today El Salvador. A Pompeii-like site, buried by a smaller eruption three centuries later, tells the story of how the country was resettled

by Payson D. Sheets

The hazards of living in a volcanically active area were dramatically illustrated by the May 18, 1980, eruption of Mount St. Helens in Washington. The lateral blast killed dozens of people and destroyed 150 square miles of forest, while the ashfall disrupted agriculture and transportation hundreds of miles downwind. Less obvious than the disadvantages of living in a volcanic area are the advantages, which include the fertile soils that develop as volcanic ash weathers. In fact, the agricultural productivity of the state of Washington owes much to the periodic eruption of the Cascade volcanoes during the past 10,000 years. My recent archeological research in El Salvador has revealed a similar balance of risks and benefits for the southeastern Maya people, who lived along the volcanic axis of Central America. About A.D. 260, a massive explosion buried these highlands in ash, forcing the Maya to abandon them for decades—up to two centuries in the worst hit areas. One small area in this region was struck by three additional eruptions in the years that followed. These various eruptions differed in terms of the size of the area devastated and the nature of the tephra (ash and other materials) blasted into the air, but in each instance people showed a dogged determination to reoccupy the lands affected, thereby reaping the benefits of volcanic activity. El Salvador's volcanoes not only influenced the course of Maya civilization but also preserved, for archeologists, a very detailed record of prehistoric times.

The earliest evidence of an agricultural people in El Salvador is a site dating back to about 1200 B.C., although there were migratory hunter-gatherers in the area thousands of years before then. Excavations directed by Robert Sharer of the University of Pennsylvania have shown that this site, Chalchuapa in western El Salvador, was first settled by people from the Pacific coastal plain of what is now Guatemala. In addition to exploiting the fertile soils of the broad Chalchuapa Valley, these people regularly drew upon the massive obsidian outcrops at Ixtepeque, a volcano thirty miles to the northeast. Raw or only roughly shaped pieces of volcanic glass were hauled into Chalchuapa, where conical "macrocores" from which flakes could be struck, as well as various cutting and scraping tools made from such flakes, were manufactured for domestic consumption and long-distance trade. The colony of Chalchuapa prospered and grew in size after it came under the direct cultural and economic influence of the Olmec civilization about 900 B.C. A major trade route ran from Chalchuapa along the Pacific coast of Guatemala and southern Mexico and into the Olmec heartland, centered on Mexico's Gulf coast. Besides obsidian, numerous commodities—including jade, hematite, and perhaps perishables such as cotton, cacao, salt, and quetzal feathers—were traded along this route.

By about the time of Christ, the region of El Salvador was densely populated, with more than 125 people per square mile. The bulk of the population were farmers, who cultivated both irrigated and unirrigated fields. Corn and beans were probably the staples, supplemented by a variety of root and tree crops and a few wild plants and animals. From what we know about parallel developments in other regions and the limited amount of direct archeological evidence, we can conclude that Maya society in El Salvador was stratified, with an elite composed of affluent decision makers. In the towns, whose central areas were dominated by pyramids and plazas, a middle class of artisans and government functionaries was emerging.

Some of the earliest Maya hieroglyphic and calendric inscriptions are from El Salvador and adjacent southern Guatemala, showing that this was one of the most advanced Maya areas at the time. This progressiveness can be attributed, in part, to the highly fertile soil that had developed in the first millennium B.C., a period of relative volcanic quiescence. Previously deposited tephra had had time to "weather"—that is, to undergo physical and chemical change through the process of plant growth and decay and the action of the elements. Agronomist Gerald Olson of Cornell University has discovered that when well weathered, this volcanic soil has an excellent capacity to retain moisture and is rich in organic matter and in the phosphates and nitrates important for seed crops such as maize.

Jade was one of the principal trade items in Maya times. This chest ornament of the Late Classic period (A.D. 600–900) came from Nebaj in the Guatemalan highlands, not far from the jade source.

Lee Boltin

The region's volcanic quiescence was shattered by the sudden eruption in about 260 of Ilopango volcano, which has been studied by Virginia Steen-McIntyre of Colorado State University. Under the northwest corner of Lake Ilopango—a lake formed as a result of more ancient volcanic activity—a vent opened up and began spewing massive amounts of tephra into the air. The eruption was rapid; it occurred in only two identifiable stages, with almost no pause in between. Because the vent was under water, steam explosions contributed to the violence of the eruption, and the rapid cooling of magma to tephra by the lake waters created very small particles, which the wind carried long distances. The magnitude of the eruption can be envisioned from the three-foot-deep ashfall at Chalchuapa, forty-five miles northwest of the source. Eruptions can also be compared by calculating the total volume of material blasted into the air. Geologists estimate that more than a cubic mile of ash was released by the big May 18 eruption of Mount St. Helens. By comparison, Ilopango may have blasted more than ten cubic miles of ash into the air, making this eruption one of the world's biggest during the past few thousand years.

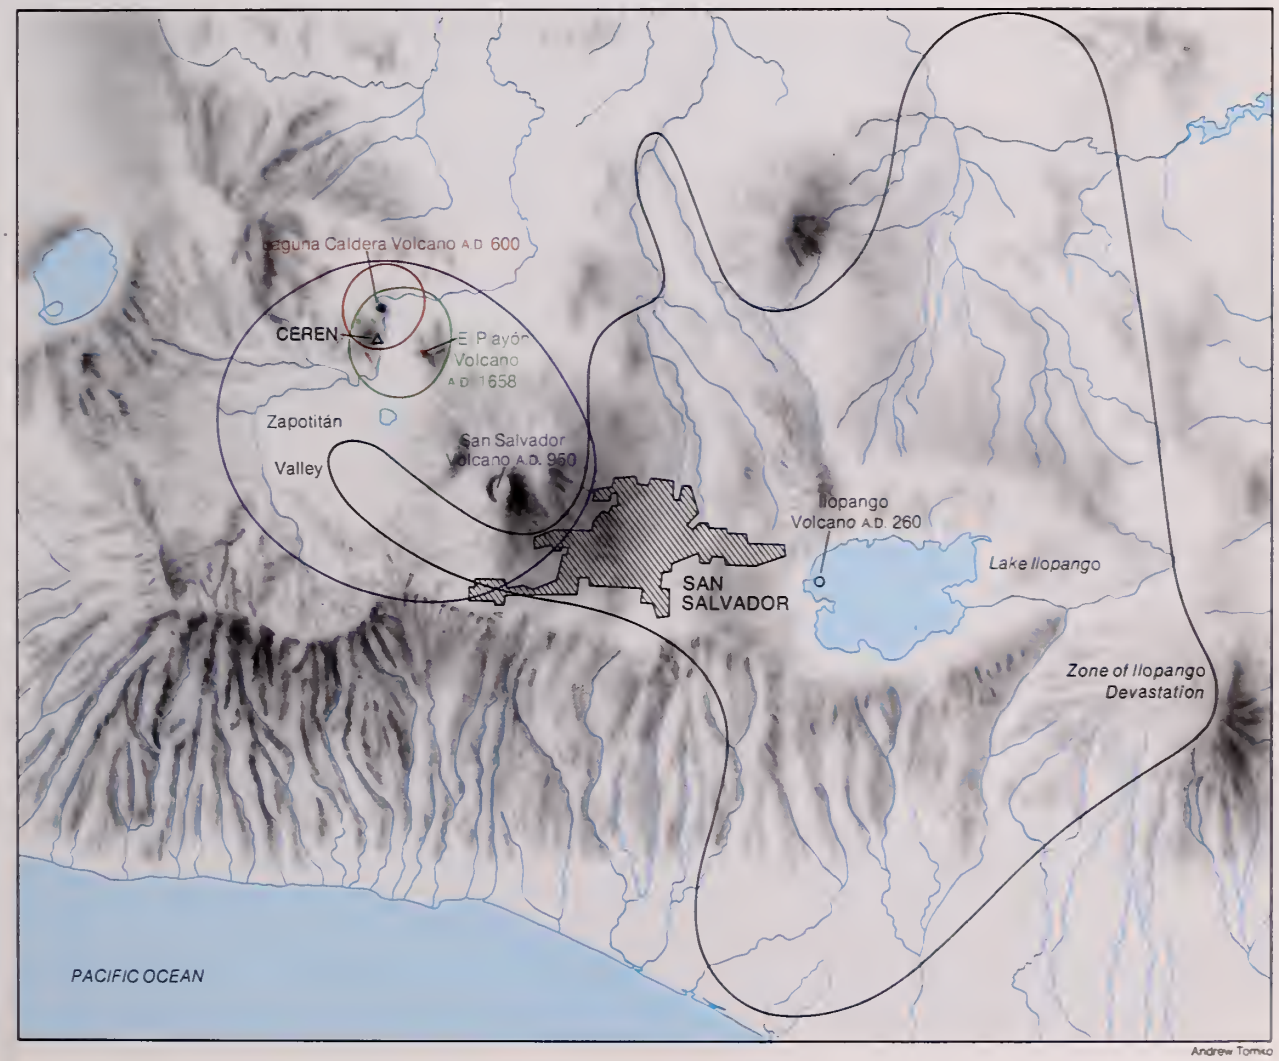
The zone nearest Ilopango was one of complete devastation, where plants, animals, and, of course, people could not have survived. This was where ash fell to a depth of 6 to 8 feet—and up to 165 feet deep nearest the source. Although we cannot yet map its boundaries accurately, we can say that this zone was elongated to the northwest, extending at least eighteen miles on that side of the volcano, evidence that the eruption plume was pushed by the prevailing winds of the rainy season, which lasts from May to November. The absence of pollen in the tephra also confirms that the eruption occurred during the rainy season.

Beyond the zone of complete devastation was an area of more than a thousand square miles where most people would have survived, but where fields would have been too deeply buried by the white volcanic ash to be cultivable. If it is even a few inches deep, fresh, unweathered volcanic ash suffocates plants by interfering with transpiration, and adsorbed elements on the grains create acids when mixed with moisture. Windblown ash sandblasts plants and can topple or bury maize and other crops in a few days. In addition, Ilopango erupted at the worst possible time for the Maya farmers—during the rainy season when their crops were growing and food stores were low. They probably also had little stored water that could be used in such an emergency. Within days or weeks, thousands of people must have emigrated.

There are some archeological indications that the refugees moved north, to the Maya lowlands. Gordon Willey and his associates from Harvard University excavated the site called Barton Ramie in Belize and found that at the same time that a series of "foreign" artifacts showed up at the site, its population doubled. The intrusive artifacts stylistically match those that had been developed in El Salvador and were in use there just prior to the eruption of Ilopango. Illopango refugees also apparently settled at a number of other sites in the lowlands of northern Guatemala and Belize. For reasons we do not yet understand, however, there are also many sites in the lowlands that suffered a population decline about the third or fourth century A.D.

The eruption forced many people to evacuate their agricultural lands, but in outlying areas, where no more than one or two inches of tephra were deposited, people could have adjusted to the changed conditions. The tephra would have caused problems for a few years, especially for farmers nearest the

Above: The area dominated by the Maya culture encompassed both volcanic highlands and lowland terrain to the north. In about A.D. 260, the catastrophic eruption of Ilopango, a volcano located in what is now El Salvador, forced the Maya living in surrounding areas to abandon their farmlands for up to two centuries. Their major trade route, which led through Olmec territory into central Mexico, was rerouted to the north. These events may help to explain why Classic Maya civilization (A.D. 300–900) is associated with the lowland areas.



Right: The eruption of Ilopango created a zone of devastation (gray line) and blanketed adjacent areas with ash. These lands were eventually resettled, but in A.D. 600 the Zapotitán Valley was hit by the eruption of another volcano, Laguna Caldera, which buried Cerén and other sites in ash (orange line). Two other local volcanoes erupted later in the valley's history, depositing ash in about 950 (purple line) and 1658 (green line).

source, but before long, as the thin ash deposit became mixed with the soil, the favorable effects of the ashfall would have been felt.

Ilopango tephra may have actually reached as far as the Maya lowlands, where the Classic period of Maya civilization flowered from A.D. 300 to 900. Recent cores from northern Guatemalan lakes, taken by Edward Deevey and others of the University of Florida, show a drastic increase in silica in the Early Classic period. Silica is the dominant material of the Ilopango ash. If chemical tests confirm Ilopango was the source of the lake-core silica, we would still have to know the depth of the ash deposit in order to tell whether the lowlands suffered any initial detrimental effects. As the tephra weathered and was incorporated into lowland soils, however, it certainly would have been beneficial.

We may speculate that Ilopango actually played a role in the emergence of Classic Maya civilization in the lowlands. In addition to possibly receiving a thin deposit of ash, the lowlands would have been affected by the arrival of thousands of immigrants. A more intensive agricultural system would have been needed to feed the enlarged population, and a more complex political and social system would have been required to organize and control it. While I am convinced that Classic Maya civilization would have emerged in any case, the process may well have been accelerated. We can even point to at least one lowland site, Tikal, that profited directly from the disaster in the southeastern Maya area. Strategically located midway between the headwaters of two river systems to the east and west, Tikal appears to have seized control of the eastern end of the major Mesoamerican trade route, which extended as far as the basin of Mexico, site of present-day Mexico City. With the old route in shambles after the eruption of Ilopango, trade was rerouted to the north, contributing to the burst of prosperity so noticeable in Early Classic Tikal.

Had it not been for Ilopango, Classic Maya civilization might have flowered first in El Salvador and adjacent southern Guatemala, instead of in the lowlands to the north. Because of the thick blanket of ash covering the countryside, however, people abandoned central and western El Salvador, along with adjoining areas of Guatemala and Honduras, for at least a few decades, and in the worst hit areas, for about two centuries. Composed predominantly of silica, the ash from Ilopango was an "acid" tephra. It provided few of the nutrients needed for plant growth and weathered relatively slowly. We will not know the details of vegetative succession in El Salvador until we have taken lake cores and analyzed the pollen, diatoms, and other sedimentary materials they contain. In general

terms, the process of soil recovery would have begun as the rains leached out adsorbed acids. The first plant recolonization was probably by lichens, followed by grasses and ferns, and finally, by bushes and trees.

Evidence of human resettlement in El Salvador is dramatically preserved at Cerén, a Pompeii-like site that I began excavating in 1978 as part of a multidisciplinary research team. Cerén lies in the Zapotitán Valley, some twenty-five miles northwest of Ilopango. People deserted the valley when Ilopango buried it in about six feet of ash. Ironically, about A.D. 600, only a short while after the area was finally resettled, a local volcanic eruption buried part of the valley once again, freezing the landscape and society in time.

Laguna Caldera, the volcano that buried Cerén the second time, is less than a mile north of the site. In contrast with Ilopango, its eruption in 600 covered only a small area—about eight square miles—with a deep layer of volcanic ash. The long-term cultural effects of Laguna Caldera's eruption were therefore negligible in contrast to the Ilopango eruption, but the event was a boon to those of us who seek to reconstruct past ways of life. This is because the layers of tephra that Laguna Caldera deposited across the local countryside had excellent preservative characteristics. First, a fine-grained tephra fell with moisture in it, packing around the leaves of growing corn plants, around the leaves and trunks of trees, and around grasses and other plants. What is left is a cast of the vegetation, and preservation is so detailed that even cellular structures in the corn plants can be observed under a microscope. The fine-grained layer, some six inches thick, was closely followed by a thinner, hot deposit of cinders and lava bombs. Richard Hoblitt of the U.S. Geological Survey in Denver has determined, by a complicated analytic technique involving remnant magnetism, that the hot layer fell at a temperature over 1,000°F, which had the effect of baking much of the buried vegetal materials, carbonizing and thus preserving them. Within a few months, additional layers of tephra accumulated, so that the total depth of ash at Cerén is between twelve and twenty feet.

Our excavation at Cerén shows that

about two hundred years after the eruption of Ilopango, people began to recolonize the Zapotitán Valley and to farm its partly recovered soils. The land had a neutral pH and was fairly rich in nitrogen, but it was very weak in phosphorus, magnesium, manganese, calcium, and potassium. And, if that were not enough, the earliest settlers damaged the soil by forest clearance, which allowed the rains to carry away substantial amounts of the topsoil. The slightly sloping cornfield we have excavated shows that the Maya farmers attempted to counteract the erosion with low, crisscrossing ridges of soil. These ridges helped to force rainwater to puddle instead of run off, maximizing infiltration of moisture into the porous soil.

Then, about the year 600, only fifty or seventy-five years after the Zapotitán Valley was resettled, nearby Laguna Caldera erupted. The Cerén cornfield was buried in twelve to eighteen feet of ash with much deeper accumulations toward the source. The corn, planted at the tops of the ridges, was only four to six inches tall. Because the cornfield was not irrigated, we know that the eruption struck early in the rainy season—in late May or early June.

Laguna Caldera not only buried and preserved agricultural fields and natural vegetation, it also preserved the houses of a village. Based on the information available at present, houses were spaced about 165 feet apart, with their agricultural fields in between. On the average, that allowed each household only about five-eighths of an acre. This would not have been sufficient to feed a family, especially since low soil fertility did not permit a high density of maize plants—only about 12,000 per acre, compared to 20,000 to 24,000 per acre in present-day fields in the highlands to the northwest. The Cerén farmers were probably farming addi-

The acropolis of Tikal represented Maya civilization at its height. Located in the lowlands of Guatemala, the city prospered after the eruption of Ilopango, when the main Maya trade route was diverted to the north.

John Keshishian

John Keshishian

The volcanic axis of Central America includes Pacaya, a volcano located near Guatemala City. In the 1960s, ash from Pacaya's relatively small eruptions was deposited as far away as Tikal, in the lowlands.

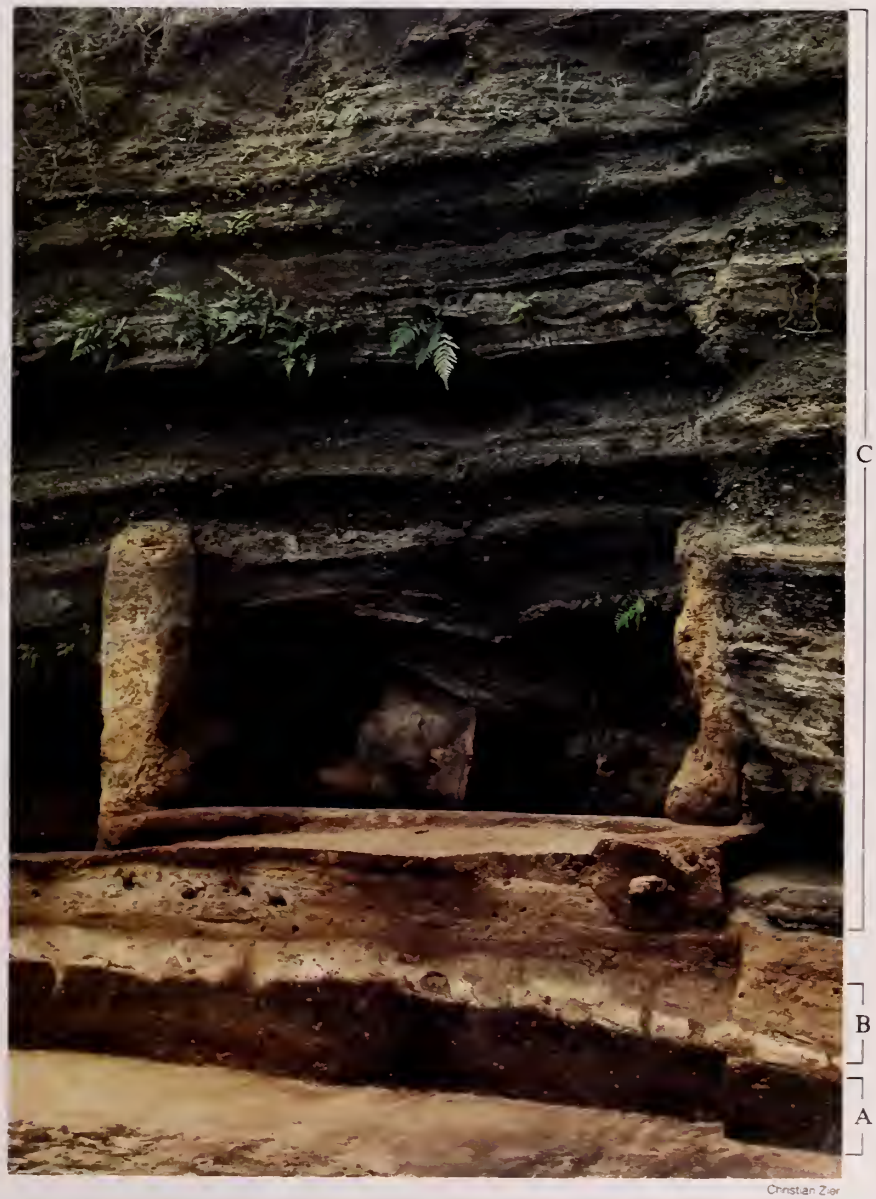
tional plots outside the village, perhaps using the slash-and-burn technique to clear land on the hillslopes nearby. Future research is planned to look for and document such extensive agriculture outside the village.

A farmhouse we excavated in 1978 was constructed by mounding and smoothing a clay platform, which was then fired as one large brick by building fires all over it. Columns and walls of clay were constructed next and a roof of palm thatch added. The columns are enigmatic, as the roof was supported, not by them, but by vertical poles coming out of the walls. I should point out we did not excavate the entire house because its northern portion had been bulldozed in 1976, when the Salvadoran government was constructing a grain-storage silo complex. Local people who observed the bulldozing reported seeing a number of bodies on the floor of the house, clustered around a few polychrome pottery vessels. If this description is accurate, it could be that the Maya residents gathered around their ritual pottery for a final ceremony to try to save themselves from the eruption of Laguna Caldera.

There were various activity areas within the farmhouse. In the pantry, we found four large pottery storage jars—crushed by the tephra overburden—and a grooved stone maul. Two of the vessels were empty when we found them; they may have been empty that spring day or they may have contained liquid that did not preserve. The other two vessels contained small beans, *frijoles de arroz,* which are still cultivated in the highlands today.

One room contained a pottery-making area. On the floor was a lump of prepared potter's clay, a lump of hematite (red iron oxide used for paint), and an andesite flake that was used as a pottery smoother. The family in this farmhouse had polychrome vessels and apparently were making their own. They were also receiving some polychrome vessels from traders, brought from as far away as Copán, Honduras (70 miles to the north), and perhaps even from Costa Rica (360 miles southeast). These findings at a humble farmhouse require reevaluation of the idea—subscribed to by many archeologists who study the Maya—that fancy polychrome pottery is an indicator of high status.

About thirteen feet west of the farmhouse we found an outbuilding constructed much the same way as the house, with a fired-clay floor and a palm-thatch roof, but without wattle and daub walls or interior partitions. The scatter of obsidian debris south of this structure indicates that it served as an area for manufacturing stone tools. Early Spanish accounts of the Maya identify this as a male activity, while the areas we found in the main farm-



house are all associated with female activities.

The use of both clay and obsidian by the farmers at Cerén reminds us that in addition to fertile soil there are other important resources created through volcanic activity. The local clays, which the Maya used not only for pottery and houses but also to build their pyramids, is formed from weathered deposits of volcanic ash. Obsidian, the most valued material for toolmaking, is, of course, volcanic glass. Hematite, the red iron oxide these people used as a pigment, is also a volcanic product.

After excavating the cornfield, farmhouse, and outbuilding, we naturally wanted to know if there were other, similar buried and preserved houses and fields. We learned from local informants that one such structure, about 200 feet northeast of our farmhouse, was completely destroyed during the 1976 bulldozing. But how could we detect buildings under twelve to eighteen feet of volcanic ash? With a mixture of hope and desperation, I turned to geophysics. In June 1979, with geologist Hartmut Spetzler, I tried three portable instrument systems in the large field south and west of our farmhouse: a seismograph, a resistivity device to measure the passage of the electricity through the ground, and ground-penetrating radar. Each was used to try to detect buried structures as geophysical "anomalies." Within the 300-by-300-foot grid we set up, we detected a few anomalies to which the resistivity and the radar systems were particularly sensitive. With the geophysical instruments alone, however, there was no way for us to determine whether these anomalies were natural ones caused by unusual deposits or conditions of erosion or (as we hoped) "cultural" ones caused by prehistoric Maya structures.

In January 1980, I returned to El Salvador with colleagues from the University of Colorado to determine the nature of the three anomalies. We used a core-drilling rig borrowed from the geologic department of the Salvadoran government. The first anomaly cored turned out to be cultural, for the rig pulled up flooring at a depth of fourteen feet. The second anomaly drilled also turned out to be a structure, this time buried by twenty feet of tephra. (This second anomaly had an air cavity just above the floor, something we won't be able to explain until it has been excavated.) The third anomaly remains enigmatic as no unusual cultural or natural feature was detected. We have pretty much worked out the technological details of locating buried structures; all we are awaiting now is the end of the civil war that is racking the country, so that we can return to excavate more buried houses and their fields.

Given our knowledge of Maya settlement patterns, we are virtually certain that a small city or large town also lies entombed somewhere under the Laguna Caldera tephra, whose maximum depths have yet to be probed. Such a site should have a pyramid-plaza complex at its center, with palaces and possibly a marketplace and areas for craft specialists. The excavation of such a site would add immeasurably to our

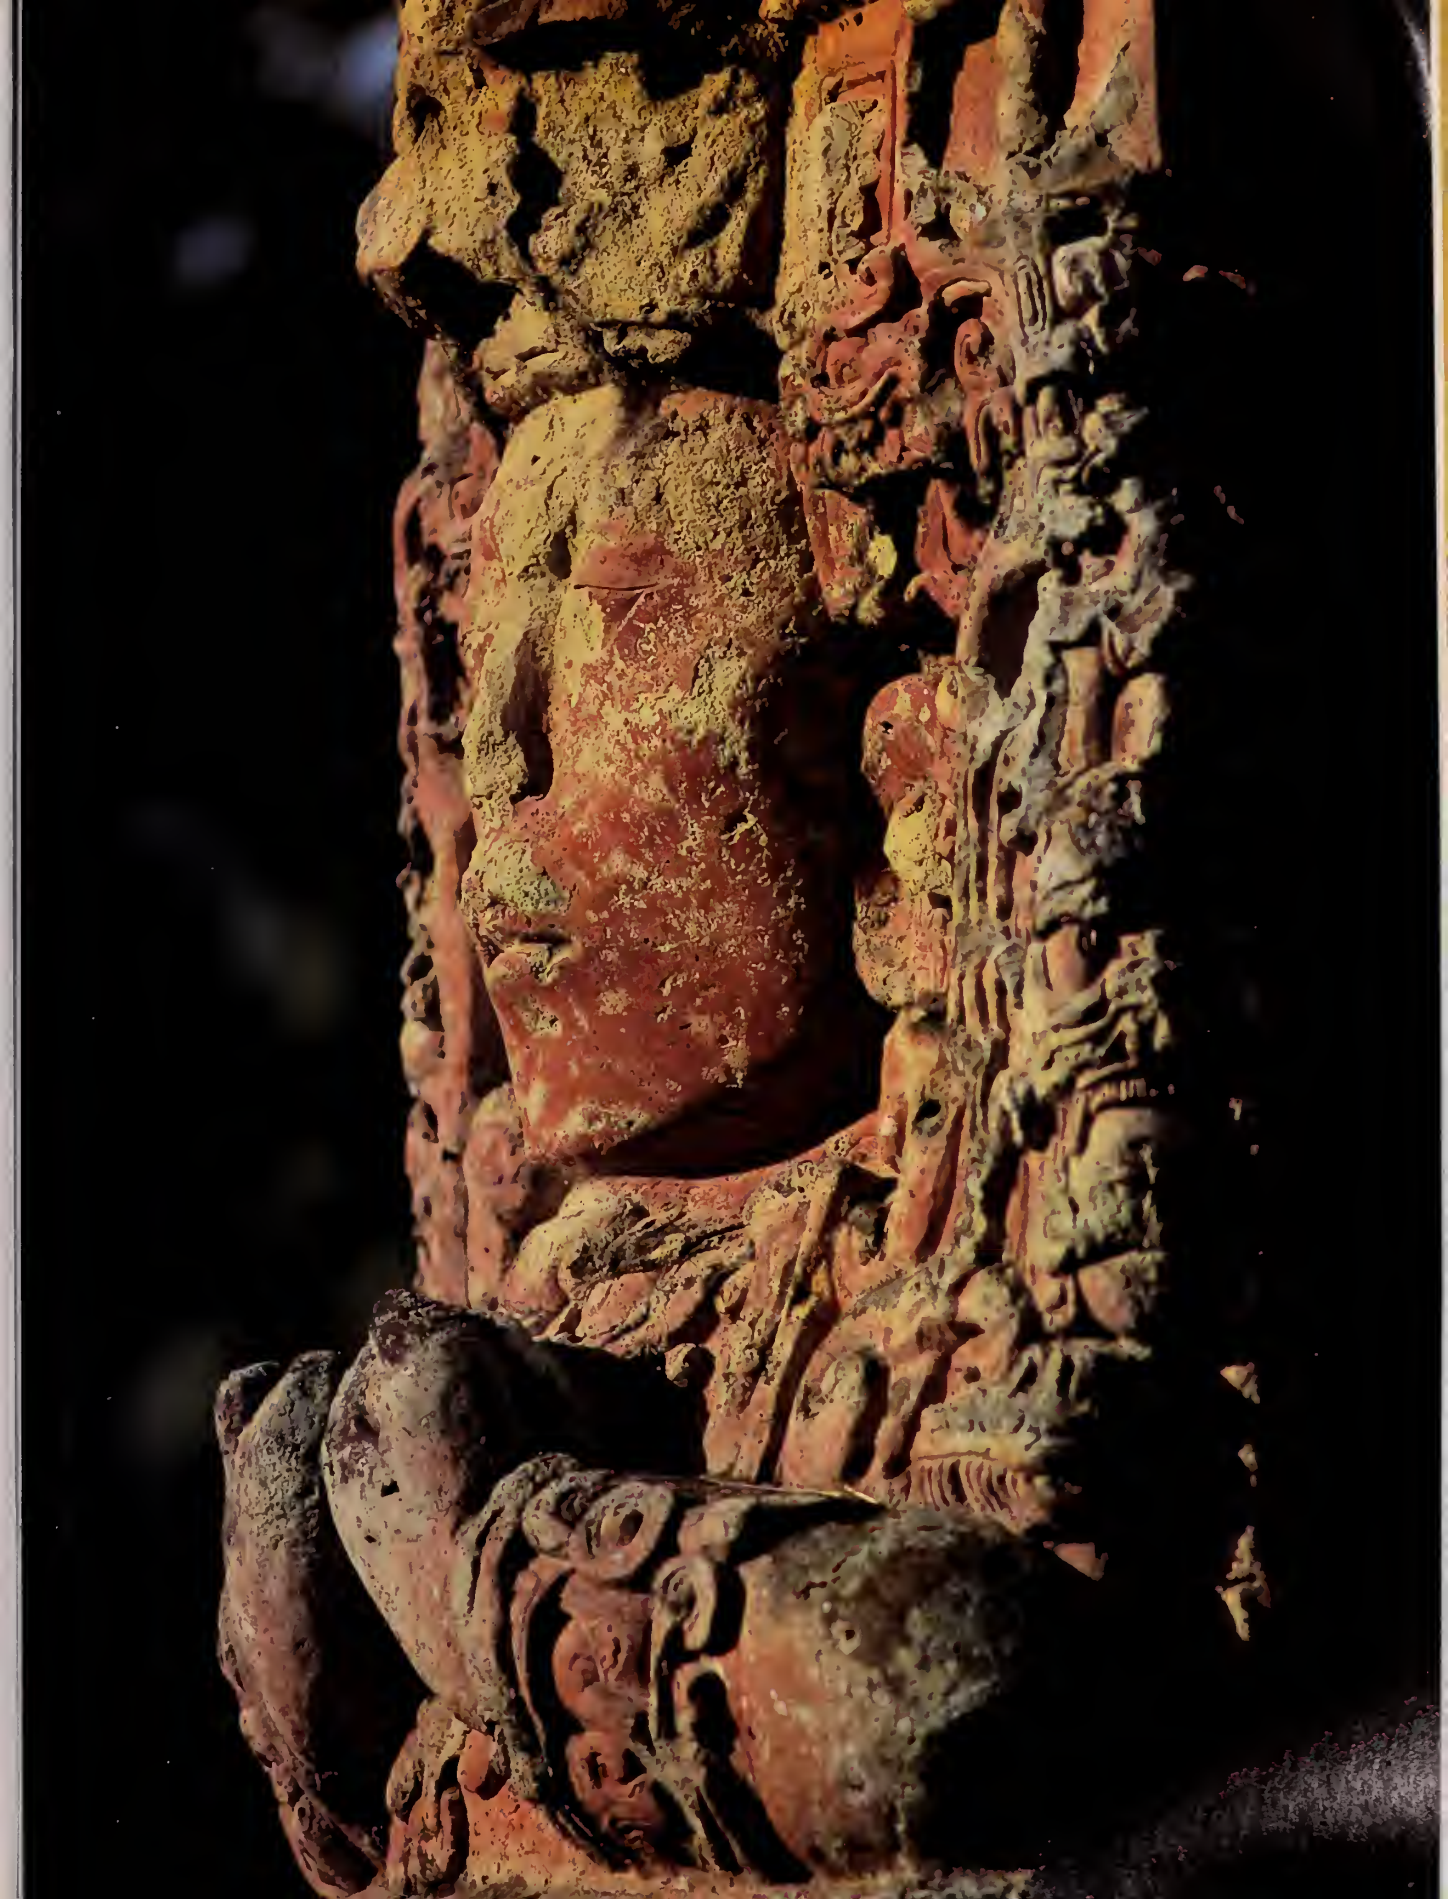
The excavation of a sixth-century Maya farmhouse at Cerén, in El Salvador's Zapotitán Valley, reveals a stratigraphic record of volcanic activity. The eruption of Ilopango in about A.D. 260 buried fertile brown soil (A) under a layer of white volcanic ash (B). After the valley was resettled, a house was built with a fired-clay floor and clay columns. This structure was destroyed by the eruption of nearby Laguna Caldera in about A.D. 600. Prehistoric remains were unusually well preserved under the thick deposit of ash from that volcano (C). Later eruptions, of San Salvador volcano in about 950 and El Playón volcano in 1658, added thinner layers of ash on top.

knowledge of the Classic Maya, given the sudden and detailed preservation caused by the eruption of Laguna Caldera. Most archeological excavations are of places that have been abandoned—often gradually—by the original inhabitants. At Cerén and associated sites, however, we should be able to find, in place, the full inventory of tools and other cultural artifacts that will show us a society frozen in time.

In the Zapotitán Valley, we have a rare opportunity to explore four main aspects of Classic Maya prehistory. First, we will be able to learn about the climate and the natural vegetation, what plants were available, and how they were used. (The preservation of botanical and other organic materials in this area is remarkable, especially for the tropics.) Second, we will be able to study the crops that were cultivated and to learn the extent to which the Maya relied on seed crops (beans and corn) as opposed to root and tree crops. We will also be able to estimate the quantity and quality of these nutritional resources and their implications for population growth. Third, we will be able to study the composition of the family or household units that made up Maya society. To what degree were the farmers self-sufficient, and to what extent did they have to raise surplus food to trade for outside commodities and to support large political or religious institutions? Finally, assuming we do locate a town or small city, we hope to learn who were the elite members of the society, what their official functions were, and how they lived. What expensive items did they enjoy as luxuries or store for redistribution to other sectors of the society? If Laguna Caldera erupted in the daytime, we may also find the remains of a fully assembled marketplace, which would provide a record of the specialty items produced locally or traded from afar. In brief, when our work can be resumed, we will examine every level of the society as it operated in 600.

Although the record of Maya civilization concealed under the Laguna Caldera tephra is particularly intriguing to archeologists, that layer of ash does not mark the end of volcanism and human settlement in the Zapotitán Valley. It was not long before people reoccupied the area struck by Laguna Caldera, perhaps within ten to twenty years on the periphery. The next volcanic eruption to leave measurable amounts of ash across the valley was that of San Salvador volcano (Boquerón), some time about 900 or 1000. The volcano, located on the southeastern border of the valley, deposited a white, pasty, sticky layer of tephra over an area of about 120 square miles. The accumulation was heaviest on the western side of the valley, no doubt discouraging agriculture, but the disruption was not serious. In 1658—in historical times—there was another significant eruption, this time of Playón volcano, near Cerén. Up to three feet of ash was deposited over some thirty square miles, and lava flowed over five square miles, burying a town and a number of farms. Since then, volcanic activity has been minor, although by no means absent.



Today, people continue to occupy this hazardous region, just as people in San Francisco continue to live and work near the San Andreas fault. As far as they are concerned, the short-term benefits outweigh the risk of disaster. In a volcanic area, however, it is not a question of whether a new disaster will strike, only a question of where and when. In El Salvador, the next major eruption could occur at any time. □

Sleight of Wing

Avocets and stilts employ a dazzling repertoire of distraction displays to deceive potential predators. Even ornithologists have been fooled

by Tex A. Sordahl

Among the most striking features of animals are those concerned with predation, a point not lost on early naturalists, who were greatly impressed with "fang-and-claw" biology. Birds of prey tearing away at their victims with powerful, piercing talons and bloody, hooked beaks were common images in avian lore. This emphasis on the weapons of such raptors as eagles and falcons, while overblown, was perhaps understandable. The defensive strategies that have evolved among some of the prey, however, are at least as fascinating to the careful observer as the attack of a predator. Consider the American avocet, with a bill shaped like a shoemaker's awl (hence the colloquial name awlbill), and the black-necked stilt, whose wading apparatus has earned it the name longshanks. While such features aid the birds in preying on aquatic invertebrates, it seems ironic that they limit the birds' ability to deal with their own predators. Slender, sensitive bills, adapted for detecting by touch small prey in muddy water, have little utility as weapons; the same is true of long, slender legs.

If avocets and stilts cannot produce a strong offense as a defense, neither can they find hiding places or refuges from predators on the open ponds and shorelines they frequent. Black-and-white plumage poised atop long, grayish blue or red legs makes both avocets and stilts prominent features of their open habitats. The attributes that gave rise to the old vernacular names for American avocets—Irish snipe, white curlew, blue-stocking—make them anything but inconspicuous.

Early American hunters ranked avo-

The slender legs and upturned bill of an American avocet are poor weapons with which to repel predators. When its eggs or chicks are in danger, however, the avocet performs a series of displays to befuddle a predator.

Tom Bledsoe

cets and stilts as decidedly second-class table birds, but did find them palatable, as do hawks, owls, and foxes. Essentially the only protection avocets and stilts have is that of being alert and fleeing from predators. Living in flocks reduces the chance of being ambushed because there are more pairs of watchful eyes. In fact, fleeing from predators works reasonably well for the birds during most of the year. But it cannot work, of course, for a chick that is unable to fly. Although parent stilts and avocets can protect themselves by fleeing, their young are usually best protected if the adults remain to interact with the predator. Interactions with predators necessarily carry an element of danger—and there hangs a tale.

Worldwide, there are up to six stilt species and four avocet species (opinions vary on how many should be recognized); all are close counterparts of the North American duo. With avocet and stilt representatives on every continent except Antarctica, this chiefly tropical- and temperate-latitude family is obviously successful in its bipartite wading-bird niche. Although none are found in polar regions, one of the avocets lives in the Andes at elevations above 9,500 feet.

Despite their widespread conspicuousness, stilt and avocet biology is poorly known. To date there have been only two scientific investigations of American avocets and one of black-necked stilts, supplemented by a few published accounts of brief studies and some recent research on an endangered subspecies, the Hawaiian stilt.

With this in mind, I set out to study the breeding behavior and ecology of avocets and stilts in northern Utah. Working at the Bear River Migratory Bird Refuge and at a private duck club known appropriately as the Barrens, I observed avocets and stilts for six years, with two and a half of those years spent in intensive study. I quickly discovered that field conditions at the Barrens are suboptimal for people. Amid snow, ice, and bitter winds, avocets arrive in mid or late March, and stilts about two weeks later. Twice a week snowstorms usually cease by the end of May, when ameliorating temperatures bring a surge of mosquitoes, black flies, horse flies, and deer flies. Summer temperatures soar to 120°F on the shadeless salt flats and not only made life unpleasant for me and the birds but also threatened the lives of the embryos encased in insolated eggshells (eggshells that are exposed to the sun).

I was particularly intrigued by the behavior avocets and stilts use to protect their eggs and chicks against predators. Eggs are usually laid in the open or in the short desert salt grass found in and around marshes (stilts have a greater tendency to nest in the grass than avocets do). Sometimes the nests are conspicuous mounds elevated above floodwaters. Regardless of nest-site details, the situation seems potentially hazardous. With a large, brightly plumaged bird sitting on three or four tasty eggs in an exceptionally open environment, a nest predator has only to spot the conspicuous adult, chase it away, and consume the eggs. So avocets and stilts, necks erect like periscopes, watch carefully as they incubate, and at the first sign of a potential predator, they slip away, making it difficult for a predator to find the cryptic eggs. But during adverse weather—snow, rain, or sizzling heat—eggs can be killed by fairly brief exposure. And during moderate weather the embryos will not develop at normal rates unless heat is applied by their parents. Inattentiveness, then, could result in a prolonged incubation period, and thereby extend the period of susceptibility to predators. Thus avocets and stilts can ill afford to be away from their nests for long periods while predators slowly search the marsh. Lacking both offensive and defensive potency, avocets and stilts have nevertheless evolved remarkable forms of behavior that cause predators to move on quickly or at least look in the wrong places for nests and chicks.

In terms of direct actions that tend to

Robert Lee, Photo Researchers

achieve these results, avocets and stilts may be the versatility champions of the bird world. I doubt that any other bird possesses such a large repertoire of antipredator displays. Distraction displays, which attract attention to the adult rather than to its nest, range from a series of wing displays, in which one or both wings are extended or waved, to false incubation displays in which the bird squats on the ground as though sitting on a nest. (Such false incubation displays are sometimes performed on seemingly inappropriate substrates, as when birds would apparently have a predator believe they are incubating in the water.) Displays may be given in rapid sequences or simultaneously, so that stilts look like whirling dervishes (avocets, being much slower, look more like drunken dervishes). Through it all the birds are continually vocal—stilts yapping raucously, and avocets piping insistently or giving pitiful-sounding "wounded bird" calls.

Standing tall over its nest in the Bear River Migratory Bird Refuge in Utah, an American avocet, left, peers intently at the photographer. Humans and other potential troublemakers rarely get close to the nest, with its cryptically colored eggs and chicks, below. The parent bird usually intercepts would-be trespassers of its nesting territory and attempts either to lead them astray with a distraction display or to repel them with dive-bombing tactics.

Tom Bledsoe

Distraction displays of avocets and stilts differ in details, but the basic form is essentially the same. Differences are mostly attributable to the ecological exigencies that have produced two different body plans within this shorebird family. Although avocets and stilts sometimes look similar in size when seen in the marsh, avocets are in fact nearly twice as heavy; the stilt, however, whose delicate appearance belies its rowdy disposition, has wings as long as, and legs considerably longer than, the avocet's. The net result is a heavy, slow, relatively powerful avocet and a skinny, hyperactive, agile stilt.

Avocet and stilt distraction displays are unusual in that they only sometimes look as much like "injury-feigning" as the displays of other bird species. It is widely held that, on encountering prey, predators evaluate their chances for success and that criteria of special importance to them are abnormal movement and appearance—attributes that often signal injury or sickness and hence easy prey. The implication is that this characteristic of predators accounts for the origin of distraction displays. And there is no disputing the abnormal appearance of a stilt or an avocet performing a distraction display.

Brief observations of avocet and stilt behavior can be misleading. Underestimating the birds' sharp eyesight, early naturalists believed their presence was undetected and misinterpreted distraction behavior as courtship. (Pair formation is actually a subtle and drawn-out affair lasting days or weeks, while copulation is associated with a set of highly ritualized behaviors lasting from forty-five seconds to a maximum of three minutes.) The following account by one early observer of black-necked stilt "courtship" serves as a colorful description of distraction:

> Although my approach was not especially careful, the two pairs of stilts . . . seemed unaware of my presence as I sat on a tussock of grass at the edge of the pool. . . . The four birds were close together . . . in the shallow water, bowing, fluttering wings and frequently half leaping–half flying . . . into the air. After a few moments . . . one bird . . . executed a flying leap . . . and . . . kicked up a shower of spray, using the feet . . . quite suddenly . . . all four birds flew steeply upward to a considerable height where they remained for some time flying . . . in wide circles, giving utterance to their loud, sharp call. Gradually . . . the four birds spiralled downward to alight in the shallow water and begin anew the . . . ritual of bow, flutter, leap, spray. This sequence was repeated again and again during the hour and a half I sat upon the grassy tussock.

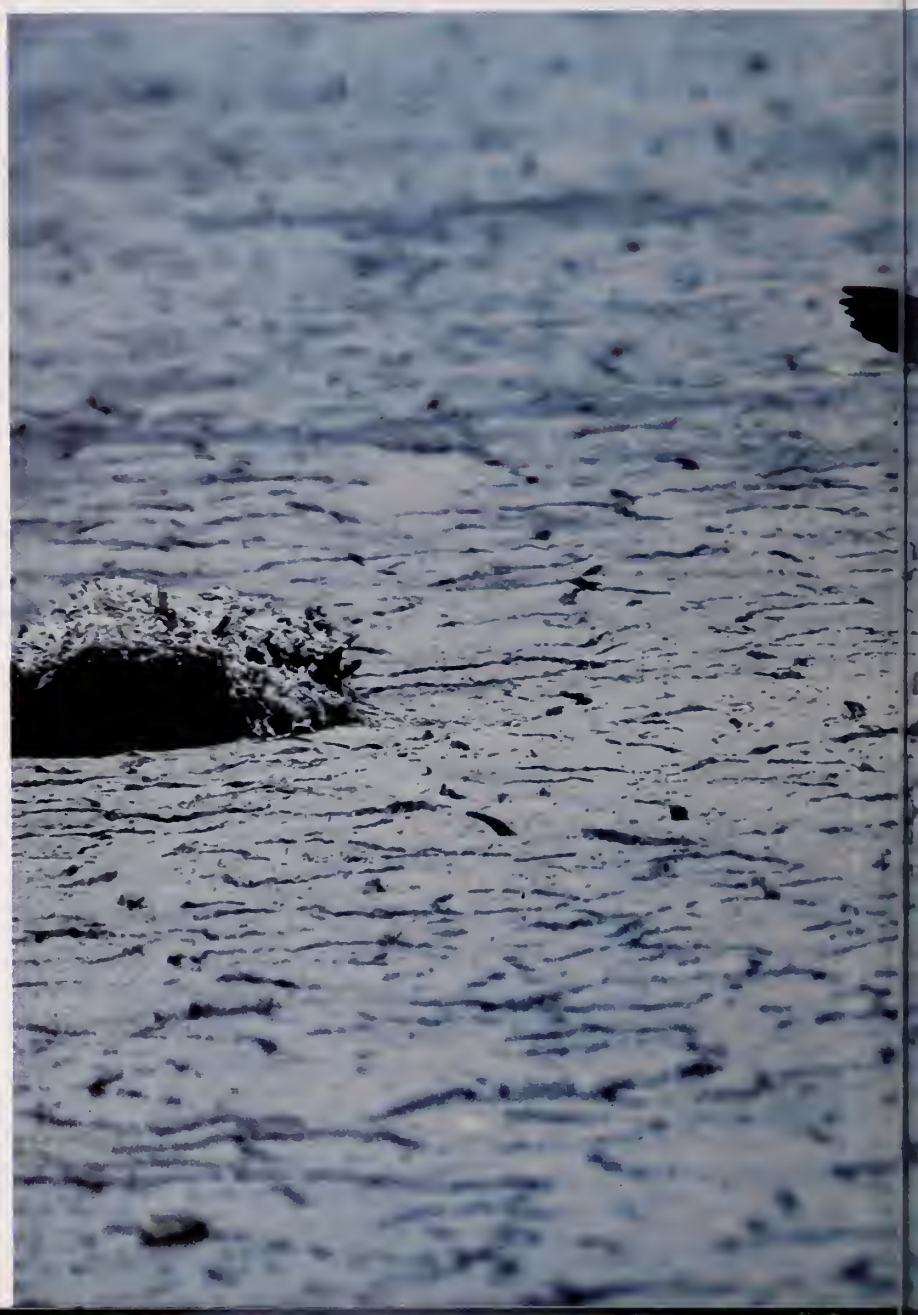
No less an authority than Arthur Cleveland Bent was taken in by the same behavior. After two brief visits to avocet breeding grounds in Saskatchewan, he wrote in 1907:

> While conducting their courtships, in May, the avocets were always amusing and often grotesque in their movements, as they danced along the shore or waded in the shallow water holding their wings fully extended, tipping from side to side, as if balancing themselves. Sometimes they would run rapidly along crouching close to the ground, frequently nodding or bowing and sometimes they would lie flat on the water or ground, with wings outstretched as if in agony. At such times they were very tame, apparently oblivious of all else, and could be easily approached.

From the birds' point of view it made no difference that their behavior was misconstrued. It accomplished its purpose—neither observer could find any nests.

Still looking for a type of courtship that is nonexistent among these birds, Bent later wrote in his *Life Histories of North American Shorebirds:* "frequently they fooled us by squatting down on the ground, as if sitting on a nest; if we went to investigate, they would run away and repeat the act elsewhere; perhaps this act carried the suggestion of mating as a part of the courtship ceremony."

The most spectacular stilt and avocet antipredator behavior is formally called the dive bomb. As is evident from the name, the birds mob their predators, swooping at them, but narrowly missing them. The avocets and stilts present quite a spectacle pursuing a great blue heron or a black-crowned night heron so hotly that it crawks, harrying a California gull until it screams wildly, or worrying a short-eared owl into drastic evasive maneuvers. Because avocets and stilts defend a 300- to 600-foot-radius around their nests and because nests are usually aggregated into semicolonies with nests no more than about 150 feet apart, the intruding predator often finds a good deal more than one pair of parents zeroing in on it. During intense mobbing a single bird generally makes a swoop every ten seconds, and I have recorded stilts swooping as frequently as every seven seconds. A mob-

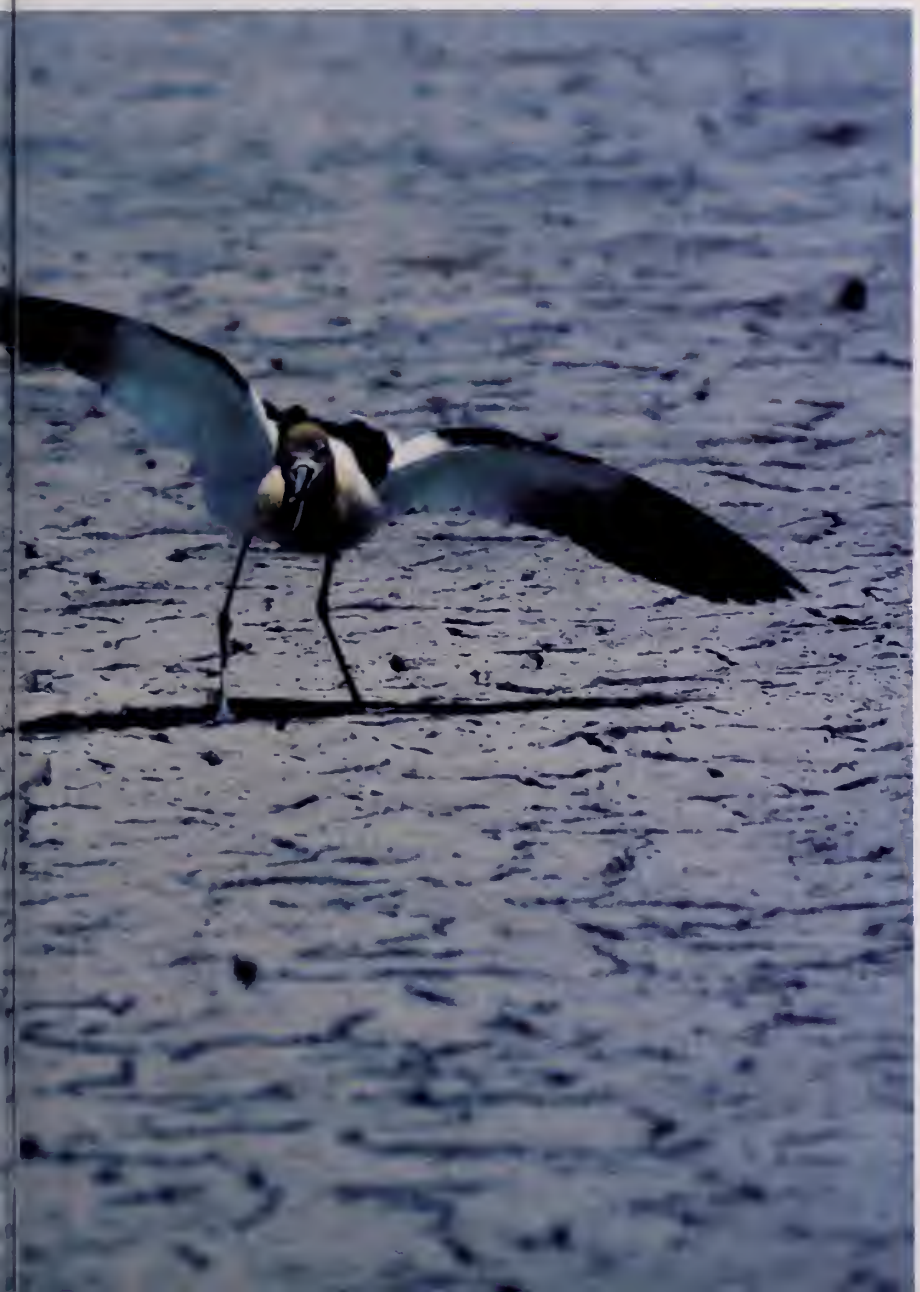


Jim Brandenburg

group may make a swoop per second. For the predator, this must be like facing an aroused beehive. Most predators withdraw rather quickly, but if not, mobbing may continue for more than an hour. An osprey, under attack by six avocets, made the most hurried retreat I have seen.

This vicious-looking behavior is almost entirely bluff. As mentioned previously, avocets and stilts lack offensive weapons and beneath the veneer of breeding-season bluster are remarkably gentle animals. Their relatively soft, flexible bills culminate in a tiny fragile hook on the upper mandible, most pronounced in avocets, that probably keeps slippery prey from slipping away. Overall, these bills are most unsuitable structures for striking a blow. Indeed, hundreds of avocets and stilts that I

Tom Bledsoe



Reacting to perceived danger, an American avocet, top, is attempting to lure the source of the threat away from its nest. The birds commonly take to the water as part of their repertoire of distraction maneuvers. Somewhat more dramatically, another avocet, right, appears to feign injury. The idea, apparently, is that predators will zero-in on abnormally behaving prey, as they often represent an easy meal. Similarly, the black-necked stilt, leaping into the air, above, is engaged in distracting a possible predator. Early naturalists, observing such odd behavior, presumed they were witnessing courtship displays.

Charles G. Summers, Amwest

have banded seemed reluctant to have their bills touched, and they certainly never pecked at me.

Most predators of stilts and avocets are not only larger than their prey but also possess specialized weapons. There is little chance for a stilt or avocet to injure a predator without suffering worse consequences itself. Physical contact with a predator is extremely rare, but as avocets and stilts swoop by, they sometimes attempt to kick predators that are on the ground. It must be uncommon for these kicks to come in contact with a live (and thus mobile) predator, but stuffed hawks, crows, and gulls that I set out were kicked so hard that they fell over. (After kicking more firmly anchored predator models, stilts sometimes shook their legs, as though they were sore.) Even without contact, water and mud flying from kicking legs must be annoying to a predator.

But why should a predator be repulsed by such sham attacks? Why does it not learn that it will not be injured? It should be admitted at the outset that avocet and stilt mobbing is not as effective as that of species capable of inflicting injuries on the predator; the hard-hitting terns, for example, seem to inspire more respect in their nest predators. But, as anyone who has experienced mobbing can attest, it is difficult not to flinch in the face of a dive bomb; it would be even more difficult for a predator that had previously been struck by a mobbing tern or even by a red-winged blackbird. If the predator has not yet seen or captured the eggs or chicks, it may be very difficult for it to concentrate on searching in the midst of a storm of harassment by the parents. Consequently, it may often be to the predator's advantage to move on quickly. But there may be something more subtle involved. There is always a slight chance that the avocet or stilt may strike the predator, even if by accident. Such a high-speed collision would probably cause as much damage to the mobber as to the predator. The avocets and stilts should theoretically be more willing to take this risk, however, because they are playing for higher stakes—failure for the mobber results in the loss of part or all of a season's breeding effort and possibly its own life, whereas failure for the predator results in the loss of one meal. Thus, in many contest situations, it is the avocet or stilt that exhibits "valor" and the predator that shows "discretion."

There are many records of predators turning on their mobbers and killing them. This ever present danger, along with the need to avoid unnecessary absences from the nest (responses to false alarms), should be a powerful selective force for the ability to recognize which animals are predators and which predators are the most dangerous. I found that avocets and stilts are indeed sophisticated in their discrimination of predators. I have seen them mob at least fifteen bird and four mammal species. Mammals and birds are treated differently, and each avian predator evokes a different response, which seems to depend on how dangerous it is to chase. Moreover, avocets and stilts distinguish a diversity of nonpredators and do not chase chick predators during the egg stage or egg predators during the chick stage.

Seventeen years ago, Dutch ethologist Hans Kruuk pointed out that there are three basic types of predators that nesting birds must contend with: those (such as the peregrine falcon) that prey on the adults but not their eggs; those (such as the red fox) that prey on adults and their eggs and young; and those (such as the California gull) that prey only on eggs or chicks. A different antipredator strategy must be employed for each. While a gull can be mobbed with reckless abandon, a peregrine must be harassed cautiously if at all; a fox is difficult to deal with but can be distracted away from the nest or chicks. Through it all, the parent must not sacrifice its life for the brood, because then all would be lost—there is virtually no chance for the chicks to survive without protection, and no chance to rear another brood. The parent must tread the

line between too little defense and too much. Whether a parent mobs a particular predator depends on the danger to the adult if it does mob and the danger to the eggs or chicks if it does not.

In their long-term study of the ecology of peregrine and prairie falcons in Utah, Richard Porter and Clayton White found that American avocets were by far the major prey species brought to aeries. Undoubtedly, this was mostly due to their abundance in the marshes and their misfortune in being the ideal size for the falcons to carry back to the cliffs. Since neither of these large falcons hunted at the Barrens, I was curious about how avocets and stilts might react to them. So I enlisted the aid of a local falconer. On the two occasions he flew his prairie falcon at the Barrens, the bird, accustomed to hunting pheasants and pigeons but unaccustomed to the teeming bird life of a marsh, soared into the clouds and wasn't recovered until the next day. The project had to be discontinued. I wish I could boast that the avocets and stilts had driven the falcon away, but they seemed to ignore him. Current programs for restocking peregrines in Utah hold promise for answering questions about the behavior of breeding avocets and stilts toward them.

How avocets and stilts obtain the information about specific predators that allows them to employ their discriminatory powers, and on what basis they discriminate, is unknown. The fineness of discrimination and the large number of animals dealt with suggest that much of it is learned. For example, stilts in Utah ignore the mostly insectivorous Franklin's gull, while in Florida they vigorously mob the similar-looking but egg-robbing laughing gull. How do they learn that a golden eagle is too dangerous to dive bomb, but ravens or marsh hawks can be chased at less risk? Since the penalty for making a mistake may be injury, breeding failure, or death, it seems doubtful that trial-and-error learning is the principal means of gaining knowledge about predators. I am tempted to speculate that chicks learn by observing their parents and neighbors during the twenty-eight days or so before they are able to fly. They should be especially attentive to their parents' behavior then because their very lives depend on running or hiding at the first alarm. But acquiring knowledge about predators in this way would entail an outstanding memory. Volant birds without eggs or chicks react only to predators that prey on adults, and the response is to flee; hence, information about egg or chick predators would not be useful to avocets and stilts until they attempt to breed, probably at age two or older. It is perhaps more likely that young breeding birds learn about predators by observing more experienced neighbors in the colony, whose reactions to predators cover for some of the young birds' naïve mistakes.

Flapping its wings and running awkwardly, this black-necked stilt is demonstrating another variety of distraction display. Such defensive behavior is only partially successful, as 40 percent of all stilt and avocet eggs at one of the author's study sites were taken by predators.

Tom Bledsoe

About 40 percent of all avocet and stilt eggs at the Barrens were taken by predators, and another 8 percent of nests failed because an adult was killed by a predator while incubating. The main culprits seemed to be California gulls and red foxes, preying on eggs, and foxes and great horned owls, preying on adults. While the birds can renest if they lose a clutch early in the season, I suspect that the very large gull population may be swamping their defense system. The avocets and stilts cannot chase all the gulls and must return to their nests without having successfully driven them off. Both the American avocet and the black-necked stilt formerly nested along the East Coast as far north as New Jersey, but these eastern breeding populations were shot out in times of unrestricted gunning. Neither species has reoccupied this area, but a stilt population has survived in Florida. Currently, stilts appear to be expanding their breeding range north along the coast from Florida, a few nonbreeding avocets are summering regularly along the coast, and state wildlife agencies are attempting to reestablish a breeding population of avocets. But burgeoning gull populations in these areas could have a significant effect on the avocet and stilt recolonizing ventures. In the future the remarkable antipredator adaptations of avocets and stilts may be severely tested. □

The Whale Behind the Tusk

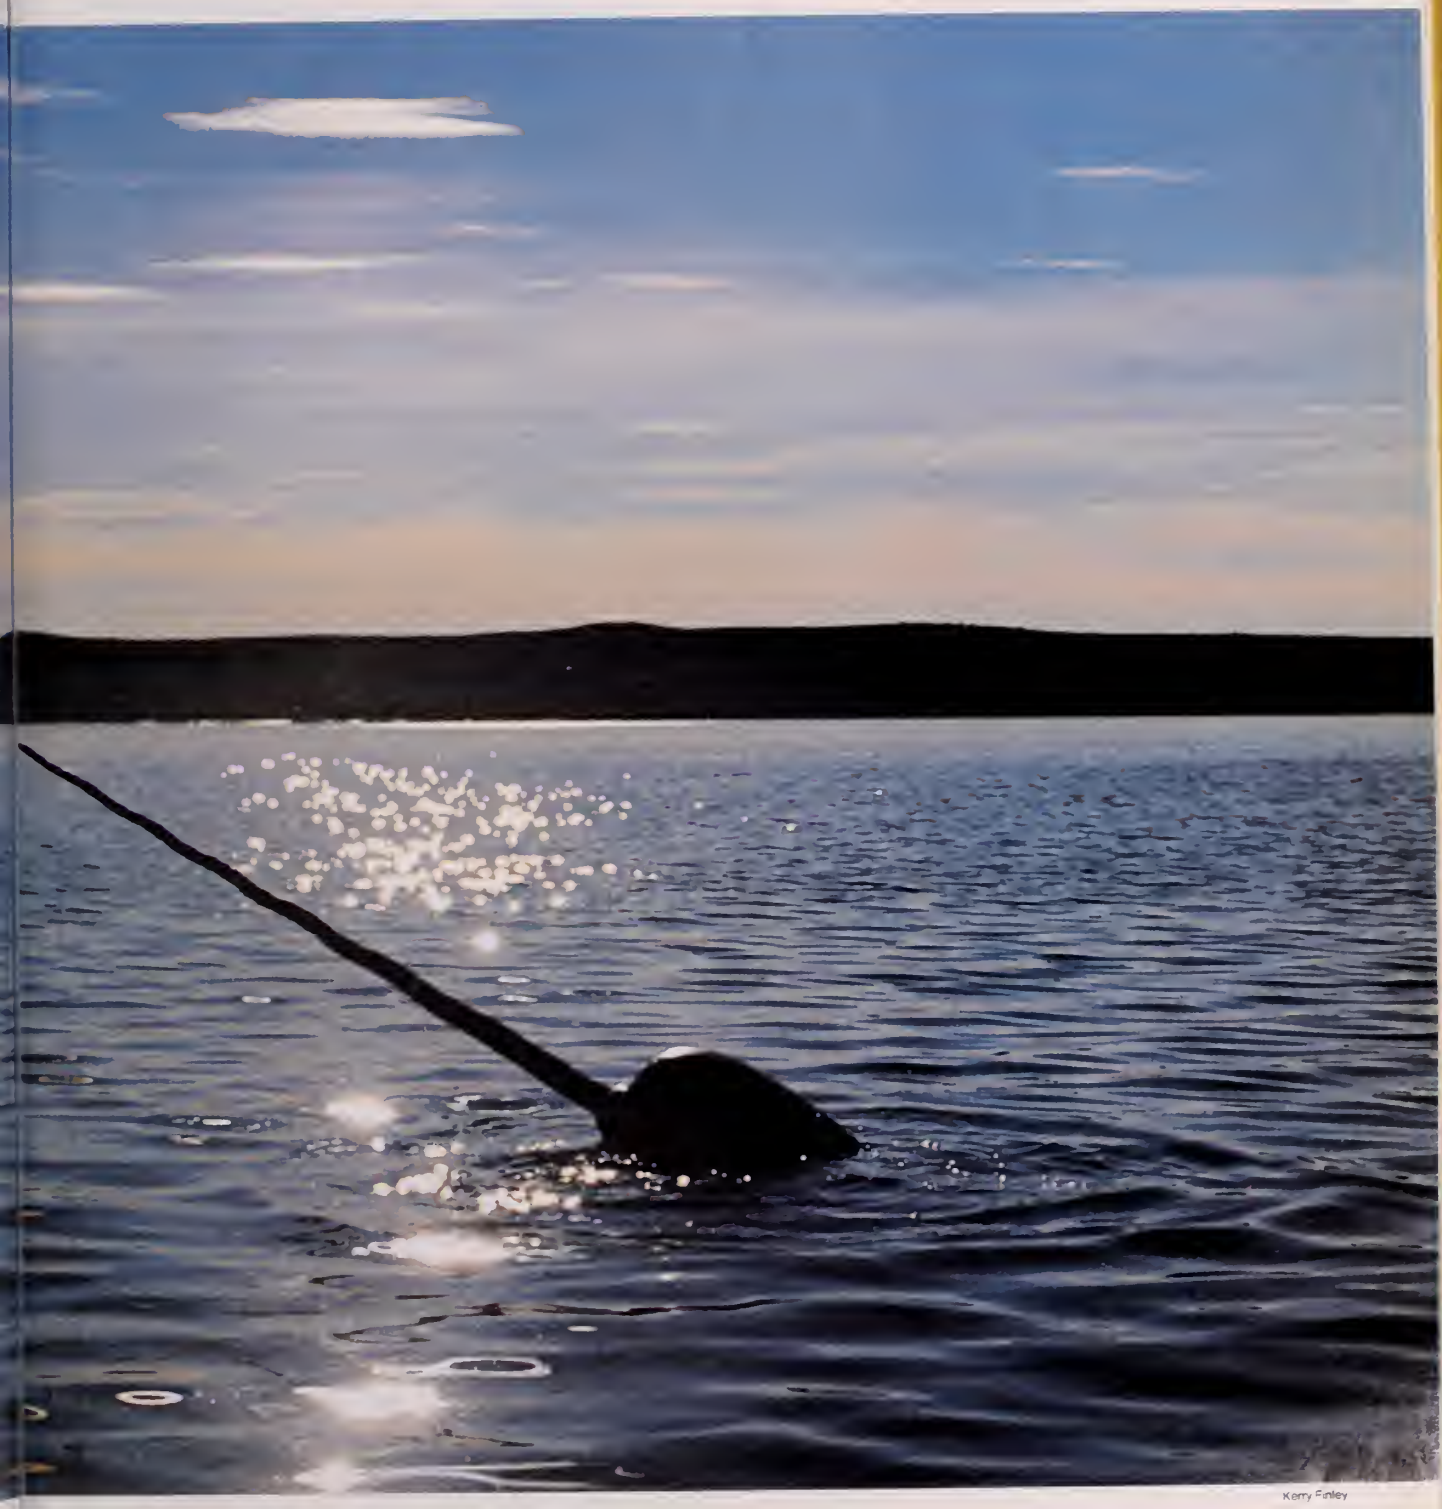
Myths and superstitions concerning the narwhal tooth have been a factor in the whale's exploitation

by Randall R. Reeves and Edward Mitchell

During the Middle Ages, European apothecaries frequently sold "unicorn horn," with the promise that it would cure epilepsy, strengthen the heart, induce perspiration, and buffer poison. The substance being offered was, in fact, derived from the ivory tooth of the narwhal, a small arctic whale. This species (*Monodon monoceros*) has only two fully developed teeth, both rooted in the upper jaw. In males the left tooth develops into a straight tusk protruding as much as seven or eight feet forward from the upper lip, its surface grooved in a left-handed spiral. Modern medicine has long since undermined the importance of "unicorn horn" as a pharmaceutical panacea, but the narwhal's remarkable tusk continues to stir the human imagination.

Most scientific explanations for the origin and function of the narwhal's tusk have not been tested by direct observation because the animal's high Arctic habitat makes study difficult and expensive. Casual observations by whalers and early naturalists gave rise to various speculations. Some argued that the tusk is used to poke breathing holes in ice; others that it is used to spear fish or at least to stir up bottom-dwelling prey. More recently, two dental anatomists speculated that the tusk operates as a cooling mechanism, allowing the well-insulated narwhal to dump excess body heat during spurts of physical activity. And acousticians have wondered whether the tusk might be useful in focusing or otherwise enhancing the echolocation signals by which the narwhal is believed to navigate and find food.

Helen Silverman, while a graduate student at McGill University in Montreal, spent three recent seasons on northern Baffin Island studying the social behavior of narwhals. She often saw the animals crossing tusks with one another, both above and below the water, an activity noted also by early Scottish whalers. Although little aggressiveness was evident during these episodes of tusk crossing, Silverman inferred that such behavior might help maintain dominance hierarchies and enable young narwhals to develop the skills necessary for performance of adult sexual roles. Unfortunately, her observations were limited to the summer season, June to October, and the narwhals' peak period of effective mating falls between March and May. As a result, whether narwhals actually use their tusks for more serious combat during the breeding season could only be inferred.



In addition to watching live narwhals, Silverman and others have examined animals killed by Eskimo hunters. A relatively high incidence of scarring is found on the heads of adult males, and more than half of them have broken tusks. One heavily scarred individual had a tusk tip embedded in the upper jaw near the base of its own tusk. This, together with reports of broken tusks into which the tip of another tusk has been jammed, is evidence that the tusk serves an aggressive function. A burst in growth of the tusk at sexual maturity has been taken as further proof of the importance of this appendage in agonistic confrontations between adult males.

Even if the evidence for its aggressive use begins to explain one function of the tusk, several interesting questions are left unresolved. For instance, of the male narwhal's two adult teeth, why does only the left one normally erupt through the gum, giving the animal an asymmetry rarely found in the natural world? Most other mammals with horns, tusks, or antlers have them in pairs (the one-horned Asian rhinoceros being an exception). Curved, paired tusks like those of the walrus, elephant, wart hog, and dugong are common in nature, but straight tusks, such as the lower jaw pair in the hippopotamus, are rare. The single, straight tusk of the narwhal is unique.

The narwhal's use of the tusk as a weapon need not rule out the possibility of other uses. In many large mammals bearing horns, antlers, and other cephalic appurtenances, these structures are important as signaling devices. If a

In male narwhals the left tooth develops into a tusk that protrudes as much as eight feet. Occasionally, in the calm waters of certain Arctic fiords, males may be seen with their tusks out of water.

Kerry Finley

Narwhals are most abundant in the Greenland Sea and in the Baffin Bay–Davis Strait area

Joe LeMonnier

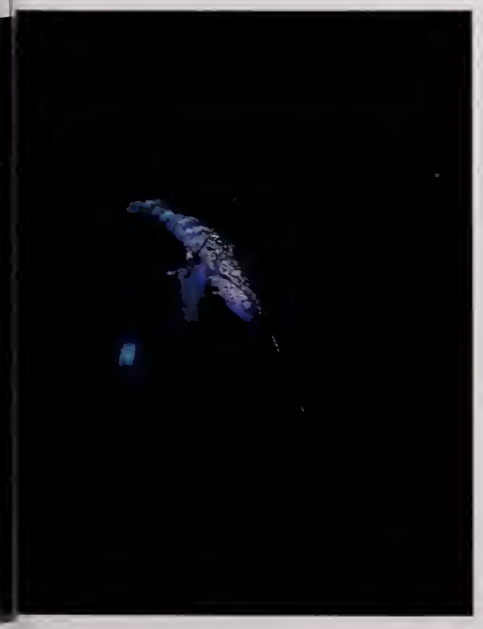
well-endowed male actually had to fight every potential challenger, he would have little time or energy left for feeding or mating. The narwhal tusk may have a signaling function. If that is the case, then it is interesting to question whether the cues involved are visual, acoustic, tactile, or some combination of these. In any event, it seems likely that narwhal society is organized in such a way that prime bulls fight each other only after other means of demonstrating dominance have proved inconclusive.

The entire issue of tusk function may never be fully resolved. Although the tusk probably evolved for one or two primary functions, it could have been preadapted for a variety of other uses. For instance, does the tusk enhance locomotion in a manner similar to that of the rostrum of billfish? Could the warming of its boundary layer by the rapid conduction of heat from the tusk's pulp chamber into the environment reduce drag and improve the swimming efficiency of large males during critical episodes of physical exertion? Or might the polished tip of the tusk act as a lure, attracting phototropic prey?

Our own research has been concerned not so much with how the narwhal uses its tusk but with how *people* use it and, in the process, abuse its bearer. We have tried, in particular, to reconstruct the economic history of narwhal exploitation and determine what kind of impact commercial hunting has had on the stocks. Our quest has met with only partial success because ivory merchants have never been eager to divulge the details of their trade. Also, we still have only a vague idea of how many narwhals there are, how many there once were, and what natural factors control their abundance and distribution.

The particular date of the European discovery of the narwhal—or perhaps one should say the recognition of the creature for what it was—is difficult to pin down. Acknowledgment of the narwhal's existence, after all, would shatter the cherished myths and superstitions built around belief in the unicorn, to say nothing of what it would do to the profits of merchants trading on the alleged medicinal and restorative properties of unicorn horns. Suppliers of narwhal tusks were less than eager to see for themselves where the tusks actually came from, and when they could no longer hide the truth from themselves, they did what they could to hide it from prospective buyers. One story about the attempted sale of a tusk to a Russian prince, related by a seventeenth-century Danish savant, testifies to the merchants' lack of scruples:

> The Great Duke being extremely taken with the beauty thereof, he showed it to his physician, who understanding the matter, told him 'twas nothing but the tooth of a fish; so that this agent returned to Copenhagen without selling his commodity. After his return . . . he exclaimed against the physician



Fred Bruemmer

who spoiled his market by disgracing his commodities. "Thou art a half-headed fellow," replied one of the Directors of the Company, "Why didst thou not offer two or three hundred ducats to the physician, to persuade him that they were the horns of the unicorn?"

In studying the history of narwhal exploitation, we have focused on two fairly well-defined centers of the animal's abundance: the Greenland Sea and Baffin Bay–Davis Strait. The only major narwhal populations known are found in the vicinity of these deep, cold basins. No attempt has been made to assess the size or status of the Greenland Sea stock but it probably consists of several thousand narwhals. Stragglers will occasionally reach the British Isles and the south coast of Iceland. Small numbers, possibly from the Greenland Sea stock, are known to have appeared near the Russian islands of Novaya Zemlya and Franz Josef Land in the past. Recent reports from the Soviet Union, however, indicate that narwhals are now seen only infrequently in these waters.

The Baffin Bay–Davis Strait stock, which may consist of two or more separate populations, is larger and better known than the Greenland Sea stock. In summer, concentrations of narwhals are found in Lancaster Sound, Smith Sound, and northern Hudson Bay. Recent surveys suggest that the Lancaster Sound component may include more than 20,000 whales. Strays from the Baffin Bay–Davis Strait stock sometimes wander as far south as Newfoundland.

Outside of these areas, the narwhal's occurrence is sporadic. It appears only occasionally along the north coast of Alaska, and rarely ventures south of Bering Strait. Soviet scientists claim that a small population is present in the northern Chukchi Sea, but the basis for their statement is unclear.

Narwhals have been observed crossing tusks with one another both above and below water. Biologists speculate as to whether more serious combat takes place during the whales' breeding season.

Narwhals were probably hunted by Europeans for commercial purposes as early as the tenth century, soon after the Vikings began to establish permanent settlements in southwest Greenland. Norwegian merchants called regularly at the colonies, and ivory and skins were important export goods. Many of the colonists' seasonal hunting expeditions to the north were sponsored by the Norse Greenland Church, which took a special interest in the acquisition of walrus and narwhal ivory. In fact, settlers sometimes paid their Peter's pence, or tithe, in ivory.

We have not been very successful in documenting the volume of this early trade. In 1126, tusks "mark'd with Danish letters writ upon them with some glutinous matter, scarce to be effaced by the art of men," were found on an Icelandic beach near the Pool of Corpses, the site of a shipwreck. These runic letters were interpreted as the marks of individual sailors who were bringing the curious "whales' teeth" home from Greenland as souvenirs. Even if this was a common practice, however, it probably accounted for relatively few tusks. Another ship with a cargo of "unicorn horns" is said to have gone aground at Iceland in 1242. This first, poorly documented episode of commercial exploitation, which we suspect to have been modest in its impact on the narwhal population, probably ended during the late 1300s as commerce between Europe and the Viking colonies declined.

Aside from continued native hunting, the next phase apparently began early in the seventeenth century. British explorers in Davis Strait, most of them having read Martin Frobisher's description of a dead narwhal found floating at the mouth of Frobisher Bay in 1577, recognized the narwhal but seldom hunted it. The tusks they brought home had usually been obtained from native hunters in exchange for glass or iron trinkets and beads. Dutch traders were active along the West Greenland coast. The logbook of a Dutch schooner anchored in a Greenland fiord in 1652, as summarized by the Danish historian Finn Gad, states:

> Immediately the Eskimos sailed out to the ships with trout, seal skins, and "sealskin coats," but they were well aware that the foreigners were most eager to get hold of some "unicorn" horn. The Eskimos had no qualms about selling their harpoon and dart heads and other bone objects, even whole tusks, and they bartered all this for nails, knives and needles.

Although British and Dutch seamen took advantage of every opportunity to barter tusks away from Eskimos, it was the Danes who cultivated and serviced the wider European market for narwhal ivory. As one seventeenth-century pundit, Thomas Bartholinus, declared:

> Nowadays the increase of [Danish] commerce with Greenland and Spitsbergen . . . has revealed the nature and frequent availability of the tusk. At all events, our merchants have filled whole cargo vessels with this alleged horn of recent years and would import it into Europe as genuine unicorn, had not the experts torn away the mask and recognized the tusk as originating from the ocean.

The "unmasking" of the unicorn and the increased supply of tusks probably softened the demand for narwhal ivory in Europe, but still there was a strong demand in the Orient, Russia, and the Middle East. An amusing story is told of how one Mukarrab Khan balked at paying 5,000 rupees for a unicorn's horn offered for sale by the British East India Company. Before buying it, he tested its effect on a poisoned pigeon, goat, and man. All died, and the offer was turned down.

The Oriental connection is especially intriguing. Although the Dutch established a lucrative monopoly on trade with Japan at the beginning of the seventeenth century, it was not until the late eighteenth century that narwhal ivory became a recognized item of licit exchange there. A botanist who visited Nagasaki in 1775 reported: "The Japanese have an extravagant opinion of [the tusk's] medical virtues and powers to prolong life, fortify the animal spirits, assist the memory, and cure all complaints." Narwhal tusks were apparently often used to ornament temples and other places of worship, and fancy dagger hilts were sometimes

carved from them. Pulverized or turned into shavings, narwhal ivory was sold as the wonder drug *ikkaku* in Japan as recently as the 1950s.

Even without the encouragement of Europeans eager to purchase tusks, the native people of Baffin Island and West Greenland would have continued to hunt narwhals. The narwhal's chewy skin, called *muktuk,* has always been a northern delicacy. Head and blubber oil from narwhals and other marine mammals made primitive dwellings glow with warmth and light during long winter nights. Narwhal sinews served as a tough but pliable thread for sewing garments and binding leather implements. Any parts of the carcass not consumed directly by people were fed to the sled dogs. Tusks, in this context, were little more than a byproduct. In some parts of the Arctic where narwhal tusks were readily available, they were the favorite material for harpoon shafts made and used by native hunters. As wood and iron became increasingly available, however, and as the trade value of narwhal tusks became more widely recognized, the incidence of natives using narwhal tusks to kill more narwhals lessened.

Narwhals were hunted occasionally by European and American commercial whalers, who from the seventeenth century to the early twentieth, sailed to the Arctic regions in search of bowhead whales. As part of his contract, one nineteenth-century Scottish whaling captain was guaranteed a 15 percent commission on any narwhal ivory he brought home. Commercial whalers generally harpooned "unies" for sport, but their preferred prey was unquestionably bowheads. Nonetheless, fancy walking sticks and even bedposts could be fashioned from narwhal tusks, and the blubber and head yielded a modest amount of fine oil. Commercial whalers seldom ate the skin in the manner of the Eskimos; instead, they brought it home to be tanned. "Porpoise leather," as the product was called, being tough, pliable, and waterproof, was especially popular for making boots and bootlaces. During the 1920s there was a special market in Peterhead, Scotland, for narwhal skins, which were shipped to France for the manufacture of stylish gloves.

However "incidental" narwhal hunting may have been to the commercial whalers, their presence in the Arctic led inevitably to the establishment of permanent trading posts where commerce in narwhal products was conducted on a grand scale, at least for a few years. Several free traders (as distinct from the giant Hudson's Bay Company monopoly) came to the Pond Inlet area on northern Baffin Island during the early twentieth century. They prospected for gold (unsuccessfully) and bartered tobacco, firearm ammunition, and, sometimes, winter rations for skins and ivory. Although we have only a sketchy record of these transactions, we do know that in 1912 three tons of ivory, probably most of it from narwhals, were taken out of Pond Inlet by the free traders. This amount would have required the slaying of about 600 tusked narwhals.

Henry Toke Munn, a Scotsman, made narwhal exploitation his particular specialty. With the help of a dozen native families, Munn operated a unique whaling station near Pond Inlet devoted entirely to the catching and processing of narwhals. According to an old Hudson's Bay Company report, in an "ordinary" year Munn's "factory" processed the oil, skins, and ivory of 500 to 600 narwhals.

An important aspect of the modern narwhal hunt is the loss of wounded and dead animals. The traditional Eskimo method of first harpooning the whales, then killing them, resulted in few such losses. Polar Eskimos of Greenland's Thule District still hunt narwhals this way, and they apparently lose very few of the animals they strike. In Canada, however, most hunters begin by shooting at narwhals with high-powered rifles, sometimes from long range, in hopes of crippling the prey to allow closer approach. As firearms have been available to the native narwhal hunters of northern Baffin Island since the late nineteenth century, these weapons have come to be regarded as essential tools of the trade. Consequently, wildlife managers and biologists, when assessing catch levels, must correct landed harvest figures to take into account significant hunting losses caused by the rifle-first technique. In our evaluation of the early twentieth-century removals by Eskimos on behalf of traders, we have had to assume that, in addition to those whales that were landed, some whales were killed and lost and some were mortally wounded. Also, as many untusked females as tusked males are usually killed, so that the volume of ivory traded grossly underrepresents even the landed catch.

One conclusion of our study is that the decade from 1915 to 1924 was prob-

Helen Gerson

ably a peak period for hunting mortality in the Baffin Bay–Davis Strait stock. Not only were Munn and the other free traders encouraging the Eskimos and supplying ammunition, but during this period there were also several exceptional catches due to ice entrapment that served to inflate the numbers. When weather conditions change abruptly at the end of the brief Arctic summer, narwhals sometimes become trapped in small pools of open water and are unable to swim under the miles of ice that have formed between them and the open sea. This phenomenon, usually referred to by the Greenlandic term *savssat,* enables hunters to kill large numbers of narwhals with relatively little effort.

In the severe winter of 1914–15 a series of *savssats* were exploited by hunters in Disko Bay, West Greenland. The slaughter was described in the restrained prose of M.P. Porsild, director of the Danish Arctic Station in Disko:

> Every man placed himself astride a hole with his rifle loaded, awaited calmly the arrival of a school, shot one of the animals—if possible a male with a tusk—and harpooned it immediately after the shot; or, if he were exceptionally clever, he simply seized the animal by its nostrils or by one of the flippers. He then enlarged the hole, pulled his prey up, and proceeded with the flensing. By this procedure the cleverest and coolest of the hunters got up to seven animals a day without leaving the spot first chosen.

Altogether, the local Greenlanders killed more than 1,000 narwhals that one winter. We have reason to believe that during the ensuing decade two *savssat* hunts in the northern Baffin Island region accounted for more than 3,000 killed narwhals. Adding the sum of these abnormal kills to estimates of the annual average catches for Canada and Greenland, we concluded that approximately 11,000 narwhals were removed from the Baffin Bay–Davis Strait stock by hunting during the decade from 1915 to 1924.

Munn left the Arctic in the mid-1920s, and in his absence the Hudson's Bay Company encouraged the people of northern Baffin Island to trap foxes with more zeal than they had under the influence of Munn and the free traders. They certainly did not stop hunting narwhals, but we have no record of subsequent catches that match those of the first three decades of the twentieth century. It is possible that the Great Depression and the Second World War, particularly in combination with the Hudson's Bay Company's emphasis on fur trading, had a negative effect on the demand side of the narwhal market. By the late 1960s, however, ivory prices were on the increase.

There seem to have been regular fluctuations in the price of narwhal ivory, but the causes are difficult to identify. The price of "unicorn" in Frankfurt apothecaries dropped from 64 florins per half ounce in 1612 to only 4 florins in 1669. Either consumers had lost their credulity or Danish merchants had glutted the market. In 1868 the British naturalist Robert Brown wrote: "The price of Narwhal's ivory . . . of late years . . . has risen prodigiously in value owing to the repair of the Chinese palaces, but is again falling."

We are particularly interested in the trend of the past twenty years. A former Hudson's Bay Company employee told us that in 1961, when he worked in northern Baffin Island, he was buying tusks from hunters for fifty to seventy-five cents a pound. By 1965, the price had crept up to $1.25, but in spring of 1967 there was a sharp increase. Suddenly, the hunter could expect $10 per pound for unbroken tusks. Since 1973, when narwhal ivory was selling for $15 per pound at Pond Inlet, the price has climbed dramatically. In 1974, it reached $25, then $30 in 1975, and $35 in 1976. Unbroken tusks were selling for $45 per pound in Pond Inlet in 1979, and the largest one sold in that year, weighing more than twenty-two pounds, fetched $1,043 for the hunter. A premium is usually paid for tusks longer than seven and a half feet and for the rare "double tuskers," or skulls with two fully developed tusks. We know of one such bidental skull that sold for $5,000 in 1979.

The prices paid to hunters, although they are, of course, related to prices paid by the ultimate consumers of the product, do not necessarily give an accurate impression of the value of narwhal ivory on the retail market. Frequently there are one or two middlemen between the hunter and the collector or the apothecary, and their high markup reflects the shadowy character of the enterprise. Unmounted narwhal tusks were sold at auction in London in 1978 for approximately £500 per meter. As far as we know the United States is at present the only country in the world where commercial exchange in narwhal products is illegal. The species is listed in *Appendix II* of the *Convention on International Trade in Endangered Species of Wild Fauna and Flora*, however, which means CITES export permits are required for narwhal products that cross international boundaries.

The International Whaling Commission's Scientific Committee recommended in 1979 that the narwhal and the white whale be added to the commission's schedule of whaling regulations. Such a move would have required member governments whose nationals hunt these species to implement conservation measures recommended by the commission. But the commission decided that according to the intent of the IWC's convention these two small cetacean species are not "whales." Therefore, narwhal and white whale conservation remains a domestic matter in Greenland, Canada, and elsewhere.

In 1976 Canada issued Narwhal Protection Regulations under its Fisheries Act. These limit narwhal hunting to

A hunter examines two adult males that were killed when they appeared in a narrow crack, or lead, in the ice. Since 1976, Canada has set annual quotas and limited hunting to permit-holding Inuit.

permit-holding Inuit, set minimum firepower requirements for weapons used in the hunt, and confer complete protection to mothers and calves. Hunters are required to make full use of killed narwhals, wasting no part that is "suitable for food." An individual hunter's tag must be affixed to every tusk and to the carcass of each tuskless female and immature male. Annual quotas are set for each settlement; the level is based on historic utilization patterns and presumed need.

In practice, this management framework leaves much to be desired. Kerry Finley, of LGL Environmental Research Associates in Toronto, was on the ice with Pond Inlet hunters during the 1978 and 1979 seasons. His record of their catch indicates that the Pond Inlet quota of 100 narwhals was exceeded in both years. Nursing females were taken, and utilization of killed animals was only partial. Most tusks were tagged and reported, but this only provides documentation of the adult male catch. During certain phases of the hunt, at least as many tuskless females were caught, but only a small percentage of their carcasses were tagged.

Our own experience suggests that the regulation forbidding waste is inconsistent with the changing patterns of resource utilization in today's Arctic. While much of the narwhal's carcass is suitable as human food, only the *muktuk,* and often not all of that, is saved by Canadian Inuit. They have no tradition of eating the meat, although the native people of North Greenland eat it fresh or dried. There are no working dog teams today in Pond Inlet or Arctic Bay, the two settlements that account for 75 percent or more of Canada's narwhal catch. In the past, much of the meat and viscera was used as dog food and the blubber oil was saved for domestic needs.

At present, the hunt for adult male narwhals in Canada is primarily a trophy hunt. Although it has some aspects of a subsistence enterprise, the cash incentive and the failure to make full nutritional use of the resource call into question the appropriateness of managing it as a subsistence hunt. As with all commercial fisheries, the sustainable yield should be assessed, and a regime that would insure against overexploitation should be instituted.

We do not know if a serious conservation problem exists. Today, the reported landed catch by Canada and Greenland combined is from 600 to 1,000 narwhals per year. Correcting this figure for the high rate of hunting loss due to sinking or severe wounding, annual hunting mortality alone may be well over 1,000 whales per year. Unfortunately, we are not certain that the whales killed by Greenlanders are from the same stock as those killed by Inuit in Canada. We have but a rough idea of how large a population is being hunted in either area. The actual magnitude of the kill and the effects of harassment on the fecundity and fitness of narwhals are completely unknown. Just as there is a need for biological research on narwhals themselves, there is a need to know more about the past and present character of the market for their tusks.

In managing the narwhal hunt, the fundamental problem of enforcement will always remain. The International Whaling Commission has no enforcement powers. It depends exclusively on the good faith efforts of member governments and, in the case of the narwhal, simply serves as a forum for discussion of scientific findings. Neither the Canadian federal government nor the government of the Northwest Territories is likely to invest the kind of resources required to police an activity so remote and individualistic. To an extent, the trade in ivory can be monitored and restricted. As scarcity, or *anticipated* scarcity, drives the purchase price higher, however, even this aspect of the hunt may become increasingly difficult to manage.

Even if a workable enforcement scheme could be devised, that may not be the best long-term approach to narwhal conservation. After all, some of the problematic aspects of the hunt, particularly the high loss rate and the waste of useful products, were caused, at least in part, by forces outside the Inuit community. Until recently, hunters were encouraged to purchase rifles and outboard motors, to replace their dog teams with snowmobiles, and generally, to adopt hunting habits designed to serve outside markets for ivory and skins. Now, abruptly in their view, the same hunters are being asked to abide by quotas that they consider arbitrary. Outside agencies that attempt enforcement, without giving hunters opportunities for consultation or even self-regulation, run the risk of working counter to the cause of conservation.

Education and cooperative decision making may offer more hope than direct confrontation. Kerry Finley met with the Hunters and Trappers Association of Pond Inlet after the 1979 season. He shared his findings with them and offered suggestions about how hunting practices could be improved. The hunters agreed to consider his recommendations, including the regular use of harpoons with floats to insure retrieval of shot whales, less hunting at the ice edge where sinking losses are high and females and calves are often taken, and restricted use of outboard motors in areas such as Tremblay Sound, which are frequented by females with calves.

It is the hunters themselves who must come to recognize their own long-term stake in conservation. The people of Arctic Bay and Pond Inlet have a diverse and rich resource base. Ringed seals, bearded seals, walruses, polar bears, wildfowl, caribou, and char still contribute to their subsistence, and the pelts of polar bears and arctic foxes add to their cash income. In addition, many men and some women are employed by government agencies or by mineral-extraction industries. Narwhal hunting is by no means essential to community survival. Rather, it is one of various sources of cash income and food. While many Inuit children of today are likely to adopt life styles very different from those of their parents, some will want to remain close to the land, maintaining by choice a tradition into which their parents were born. It would be tragic if this were made impossible by a previous generation's lack of foresight.

At long last, some of the world is becoming aware that there is a whale behind the tusk. And as appreciation of living whales increases, perhaps more of the money pumped into the Inuit economy will be for the capture of live narwhals for display and research and less will be for tusks removed from the jaws of dead animals. Development of a live-capture fishery on Baffin Island might simultaneously serve the financial interests of local Inuit and reduce hunting pressure on narwhals. Also, if many of the questions regarding tusk development and function are ever to be answered, captive subjects may be required for experimentation and close observation. □

The price of narwhal ivory is currently high, with premiums paid for tusks longer than seven and a half feet or for the extremely rare "double tuskers." This unusual specimen was taken at Pond Inlet, July, 1978.

Weeds That Ride the Rails

Railroads can be a good way for a plant to disperse—if it can take the heat and doesn't lose its head

by Robert M. Arnold

The sight, sounds, and smells of steam locomotives are among my earliest memories, and they still evoke a nostalgia for childhood hours spent on bridges or behind fences, watching trains go by. Today, despite the replacement of steam by diesel and the reduction in the frequency of trains, a walk along a railroad track is one of my favorite activities. While walking along a seldom-used rural line in Madison County, New York, several summers ago, I became aware of the profusion of weeds growing on the cinders of the railbed. I soon noticed patterns in their distribution and began to wonder about the adaptations that might be necessary for a plant species to colonize what seems, at first sight, such an inimical environment. What started as casual curiosity led to speculations that would become the major focus of my research.

As enjoyable places to study weeds, railroads have no equal for me. Just

looking along the tracks to where they curve out of sight gives me a powerful urge to find out what lies beyond the bend. While walking in pursuit of this ever receding goal, I find the opportunity to observe plants and animals and to enjoy the surrounding landscape, whether rural or industrial. Seldom-used rural lines are ideal for a study of plants because the relative infrequency of maintenance insures a large weed population. Urban settings, however, can be just as interesting, for even a well-maintained, plant-free main line in the middle of a large city usually has infrequently used loops or sidings on which plants can grow in astonishing numbers and variety.

The railroad line where I carry out most of my fieldwork crosses a swamp on a raised embankment, intersects several roads and farm tracks, branches to form a siding for a farm-supplies depot, goes through a cut in a hill topped by cornfields and pastureland, parallels a creek, and passes through stretches of both deciduous and coniferous woodland, all in the space of a few miles. Built on a bed of imported cinders or stones, homogeneous from one end of the line to the other, a railroad would be monotonously uniform without such variety in its surroundings. As the environment of a railroad changes, so does the vegetation adjacent to, and encroaching on, the tracks.

The number and diversity of plants along a railroad are generally greatest near an intersection with a road. Common roadside weeds, such as Queen Anne's lace (*Daucus carota*), ragweed (*Ambrosia artemisiifolia*), and wild parsnip (*Pastinaca sativa*), are well represented at these locations. The seeds of many of these plants can be found in dried soil material scraped from the underside of motor vehicles. Picked up from plants growing along roadsides, these seeds may shake loose as the vehicles bounce over the uneven road surface at a railroad crossing. Roadside plants that become established at crossings may then spread along the tracks in both directions as their seeds are dispersed by the wind or by passing trains. Weeds of dry fields and meadows are also abundant along railroad tracks close to crossings. At railroad crossings that transect farm fields, pastureland weeds, such as clovers (*Trifolium* spp.), horseweed (*Conyza canadensis*), and wood sorrels (*Oxalis* spp.), are found growing in larger proportion than roadside species. These species are undoubtedly spread to railroads by farm vehicles as they cross the tracks in transit from one field to another.

The best way to gain an appreciation of the changes in plant distribution along a railroad is to walk alongside the tracks from one road crossing to the next, especially if the distance between the two is at least a mile. Most of the plants are clustered within a few yards of the road edge at each crossing, with a long stretch of almost bare cinders between crossings. The few scattered plants that do grow along the tracks in these otherwise bare stretches usually belong to species different from those found near the road. Representative of the vegetation immediately surrounding the tracks, the plants that grow on the railbed may be grasses where the line is in a cut, horsetails near a marsh or swamp, or small tree seedlings, doomed to a brief life, where the line passes through a patch of woodland.

Plants that grow along railroads are subject to both stress and disturbance. Stress includes all conditions that act to restrict the growth of a plant. A shortage of water is probably the major stress factor for railroad plants because water drains quickly through the porous cinders or gravel, particularly if the railroad is built on a raised embankment. In addition, railroads are generally open, exposed places where the hot summer sun and the wind quickly dry the cinders, even after the heaviest of showers. After spending many July and August days bent over the burning hot rails collecting data, I have come to appreciate the baking heat that railroad plants must endure. Some essential minerals may also be in short supply because of rapid leaching. Shortages of

Robert M. Arnold

water and minerals are less likely to be a problem along railroads close to the edge of a road because there is commonly a layer of soil mixed in with, and sometimes completely overlying, the cinders at these sites. This soil is probably washed from the edge of the road by rainwater. I believe that the better growing conditions provided by this soil material, and the abundance of seeds deposited by vehicles, account for the large diversity of plant species close to the edges of roads.

Disturbance is at least as important as stress in limiting plant diversity along a railroad. As soon as it emerges into the air, a seedling runs the risk of being trampled underfoot, smeared with oil by a passing train, or eaten by an herbivore. To those individuals that survive these insults, the *coup de grâce* is delivered by the railroad company, which sprays weedkiller on the tracks every year, usually in midsummer. This maintenance practice means the end of life for the plants and the end of the field season for me. More than any other disturbance phenomenon, spraying determines which species of plants will flourish on railroad tracks from year to year. It prevents the establishment of plants, including most perennials, that flower and set seed only after an extended vegetative period, and it selects for those plants, primarily annuals, that grow quickly through a short vegetative phase and then flower and set seed early in the summer. By the time the seeds of these annuals are ready to germinate at the beginning of the next growing season, the weedkiller from the previous year will have decomposed or been leached out of the surface layers of the cinders. Once a railroad is closed, however, disturbance becomes much less severe, and perennials, with their ability to overwinter, will eventually outcompete annuals, which must start anew from seed each year.

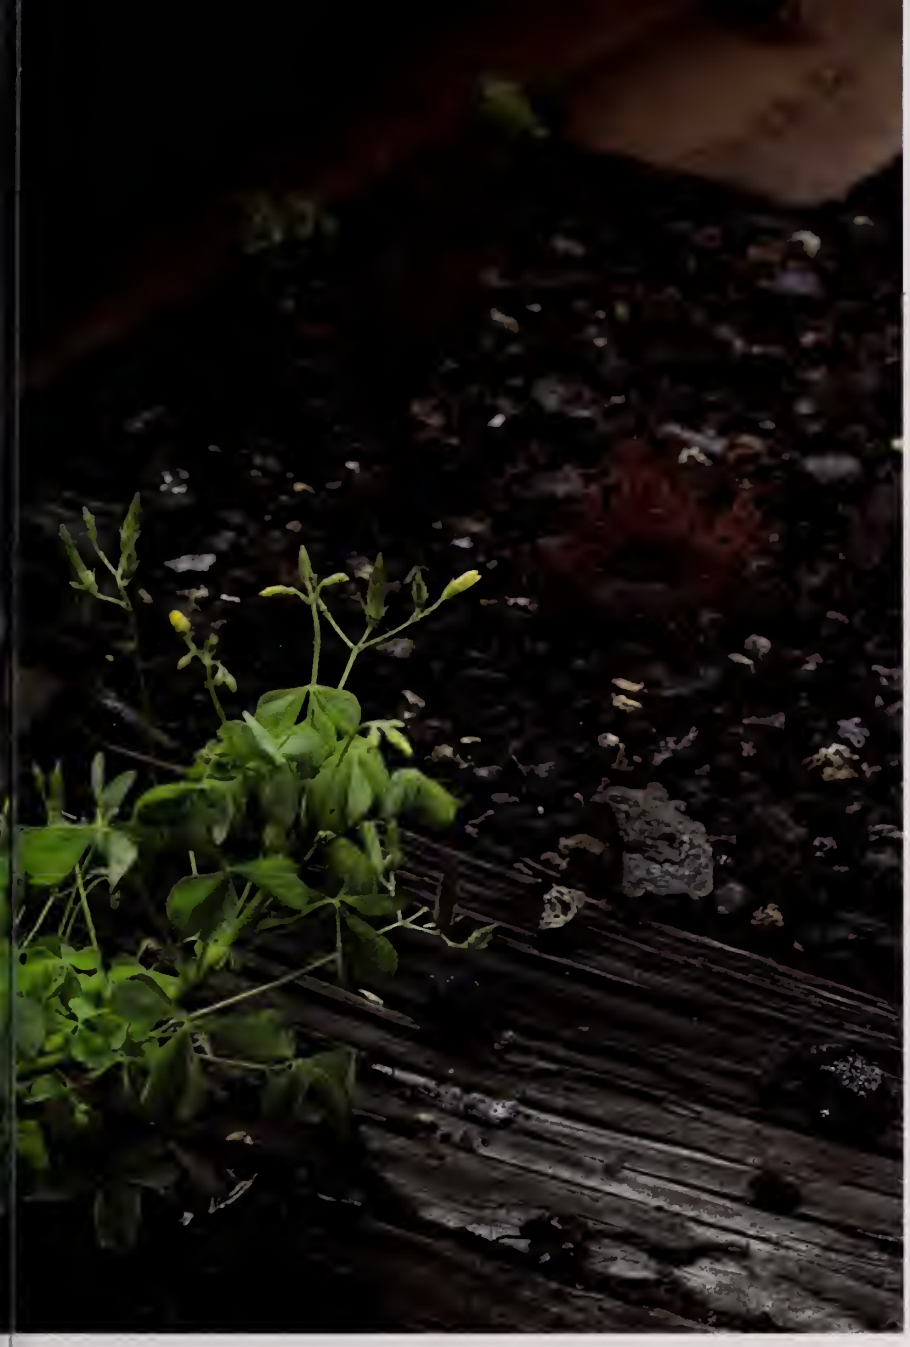
Tall plants, such as wild parsnip, are at a distinct disadvantage on an active railroad. If trains do not pass by too frequently, however, some individuals can set seed before they are decapitated.

On an active railroad, plants of small stature have a competitive advantage because tall individuals are likely to be decapitated by a passing train. Some tall species, such as wild parsnip, Queen Anne's lace, and common mullein (*Verbascum thapsus*), do grow on railroad cinders. On an infrequently used line, individuals of these species may grow to be several feet high in the interval between one train and the next. The first train to travel along the line after such an interval chops the tops off the tall shoots. This does not necessarily spell doom for the plants: I have often seen individuals of wild parsnip and Queen Anne's lace flowering on uncharacteristically short shoots that grew following decapitation of the first-formed, long shoot. Mullein, however, does not have such a mechanism of regeneration. The rosettes of leaves formed by this biennial in its first year grow well on railroad cinders, but individuals that grow too close to the tracks will probably have their single flowering shoot cut off by passing trains long before they can set seed.

Of all railroad weeds, dwarf snapdragon (*Chaenorrhinum minus*) has interested me the most. In the United States, this species grows more abundantly along railroad tracks than anywhere else, contributing greatly to the appeal it has for me. I have come to admire the tenacity with which this tiny, beautiful flowering plant flourishes in the seemingly inhospitable environment provided by the dry, sun-baked cinders of a railroad. Like most weed species of railroads, roadsides, waste areas, and fields, dwarf snapdragon is not native to the United States. Ecologists believe that native weeds are the first to colonize newly disturbed areas of natural vegetation. Nonnative weed species follow, usually with human assistance, attached to clothing, footwear, vehicles, and equipment, for example. Frequently disturbed areas generally have more species of introduced weeds than of native weeds.

The original home of the dwarf snapdragon is believed to be the Mediterranean region of Europe; from there it has spread to, and become locally abundant in, dry fields and railroad cinder ballast throughout most of Europe. Before railroads existed, this species was probably confined to dry, gravelly soils in fields and waste areas. The building of a continental network of railroads during the nineteenth century provided avenues for the snapdragon's widespread dispersal throughout Europe. Dwarf snapdragon was first recorded in the United States at Camden, New Jersey, in 1874. Presumably, the species made the trans-Atlantic crossing as seeds carried along with the cargoes of ships. On its arrival in the United States, the plant encountered an existing railroad network, and since the latter part of the nineteenth century, dwarf snapdragon has spread relatively rapidly—as far as Kansas and Nebraska in the west, North Carolina in the south, and Quebec and Ontario in the north.

The reported spread of dwarf snapdragon along railroad tracks prompted me to investigate the efficiency with which the seeds of this plant are dispersed by passing trains and to compare this mode of dispersal with natural phenomena such as wind and rain. I quickly found that rain splash is not a mechanism of seed dispersal in this species: the two openings in the wall of each mature fruit, through which the seeds escape, close up completely when the fruit is wet or exposed to conditions of high humidity.



For the experiments on wind dispersal, I set up sticky traps around plants that were growing near, but not on, railroad tracks and left them for at least five days. Each trap consisted of a strip of filter paper painted with a thin layer of melted petroleum jelly and glued to a wooden board that lay flat on the ground. I arranged similar traps around other plants that were rooted in the cinders between the rails and in the path of approaching trains. Normally, most seeds that fall on the highly porous cinders quickly percolate down

through the interstices of the cinders, where they are protected from agencies, primarily the wind, that might otherwise carry them farther. Also, under most conditions, seeds that remain on the surface lie within a laminar boundary layer of still air, and only a very high wind can move such small objects (0.6 mm long and 0.4 mm wide). Consequently, I reasoned that my traps would not artificially restrict the dispersal of seeds.

I found that trains are much more effective than the wind in dispersing seeds of dwarf snapdragon for long distances. Despite the periods of strong to gale-force winds that occurred during some of the wind-dispersal experiments, in no case did I find seeds farther than eight inches from the parent plant; most landed much closer. By contrast, a locomotive and eight boxcars, traveling at about twenty-five miles per hour, dispersed half the seeds within eight inches of the parent plant and the rest up to five feet away. Some seeds might be carried even farther if they stick to the wheels or underside of a train and are dislodged later; the faster the speed of the train, the farther along the tracks it will carry seeds. Mark Widrlechner of the University of Minnesota has suggested that parts of mature plants may break off and be carried along the tracks like tumbleweed, dispersing seeds as they go. Short-range dispersal of seeds by the wind and passing trains may allow dwarf snapdragon to exploit locally favorable areas, and trains may also facilitate the long-range spread of the species along the tracks to new areas.

These findings fit well with the observed distribution of the dwarf snapdragon in the United States. In the Mediterranean region, the species spread to newly built railroads from nearby fields and waste areas. In the

Passing trains may brush against dwarf snapdragon plants, above, dispersing seeds along the tracks. Wood sorrel, left, and other pastureland weeds are common where railroads and farm fields intersect.

rest of Europe and in the United States, however, I believe the spread has been in the opposite direction—from railroad tracks to nearby fields and waste ground. This lateral spread, dependent on the relatively inefficient wind dispersal of seeds, has not progressed very far in the United States, so that the species is still restricted to railroads and adjacent areas. My belief in this lateral spread received a temporary setback when I found a large colony growing in a patch of waste ground located more than eight miles from the nearest railroad, a distance many orders of magnitude greater than can be explained on the basis of wind dispersal. My faith was restored, however, when I consulted a topographic map and found that the New York, Ontario, and Western Railroad, which closed in 1957, used to pass through the middle of the area now occupied by the weed lot.

Having established how dwarf snapdragon spreads along railroad tracks, I then began to investigate how the plant manages to thrive in its apparently hostile environment. My first interest was in finding out how many of the newly germinated seedlings, which appear in large numbers in late spring, survive the stresses and disturbances of a railroad long enough to set some seed and thus be represented in the next generation. I followed the fate of a large number of individually marked plants for four months, expecting that lack of sufficient water would be the chief cause of premature death, especially among the highly vulnerable young seedlings. What I found was completely unexpected: the vast majority of deaths were the result, not of water shortage, but of herbivory. Sometimes just the tops of plants were nipped off or small bites were taken out of leaves; at other times, whole plants were eaten. Occasionally, all that remained of my carefully marked seedling was the loop of colored thread that I had tied around it, found lying on the cinders. I failed in my attempts to catch the culprits by baiting live traps with tender dwarf

snapdragon seedlings, but from my observations of the animals prevalent in the vicinity of railroad tracks, I suspect that edge feeders, such as woodchucks and rabbits, were responsible for much of the herbivory.

Whatever the identity of the herbivores, they cause a catastrophic mortality rate among seedlings: less than one seedling in thirty survives long enough to set some seed. Plants that do survive this early predation are seldom prey to herbivores once they have formed mature fruits, perhaps because they are less palatable than when they were younger. In consequence, these plants will most likely survive to the end of the growing season several months later. They may grow to be relatively large (eight to ten inches tall, with extensive branching), and each may produce many thousands of seeds. My present record holder is a specimen I found at Corning, New York, in July 1979. This splendid individual was thirteen inches tall, had sixty-two branches (giving a total stem length of almost fourteen feet), and bore 63 flowers and 383 fruits. Within its reproductive structures, even if no more developed, this plant could produce more than 24,000 seeds! The record holder for smallest size at maturity was truly a dwarf snapdragon, just two-thirds of an inch tall with a single flower at the top of its unbranched stem.

The finding that lack of sufficient water is not the principal cause of seedling mortality does not eliminate it as a source of stress for railroad plants. The cinders become so dry and dusty after just a few days without rain that water shortage must be a severe problem during much of the summer. Since competition for the small quantities of water present will be particularly intense where plants grow close together, I was not surprised to find that tall, reproductively successful dwarf snapdragon plants grow well separated from other plants and that where the plant grows in dense patches of vegetation, only small individuals with few reproductive structures are found. Dwarf snapdragon is invariably absent from crossings that are heavily overgrown with other species of plants. These observations suggest that the species is a good colonizer of bare cinders but either fails to grow or is outcompeted by other plants in areas of the railbed that hold more water, perhaps because of local accumulations of soil.

Dwarf snapdragon seeds will germinate only when water is present in small quantities. Seeds placed on moist filter paper absorb water and rot; none of them ever germinate. The only time I have ever succeeded with a laboratory germination experiment was when I planted seeds in pots containing railroad cinders and watered them very sparingly. Much work remains to be done, however, before I can understand how this plant, once it has germinated and taken root, manages to survive without rain for long periods, sometimes several weeks. Its tiny root system, penetrating less than one inch in any direction into the cinders, can have access to water for only a short period after rain or, during a dry spell, from the early morning dew. Water loss is no doubt minimized by the small, narrow leaves, but other anatomical modifications common to plants of dry habitats—sunken stomata or a thick, waxy cuticle covering all external surfaces—are absent in this species.

Dwarf snapdragon plants that survive the attentions of herbivores and are not overcome by a shortage of water have only a short period in which to set seed before they are killed by herbicides. I found that all individuals that grew to a large size and produced a large number of seeds began flowering when they were only about one to two inches tall and before they had begun to branch. I have never found a dwarf snapdragon plant taller than about two inches that did not have flowers or fruits. Clearly, one reason dwarf snapdragon—and no doubt other railroad weeds—can be found at a given railroad crossing year after year, despite the weed-control program of the railroad company, is that most individuals set seed after a short period of vegetative growth and before the midsummer weedkiller application.

Before a flower can give rise to a mature fruit, it must be successfully pollinated. Wind pollination, common among many successful weed species, is prevented in dwarf snapdragon by the enclosure of the male and female reproductive structures (stamens and pistil) of each flower in a two-lipped floral tube. Several aspects of the flowers suggest insect pollination: the colorful appearance of the flowers, the arrangement of the lower lip of each flower as a possible landing platform, and the presence of two magenta-colored stripes, richly clothed with glandular hairs, on the inside of the lower lip. Like a pair of fluorescent arrows, these stripes, which are sufficiently bright to be visible from outside the flower, point the way to the nectar and pollen in the interior of a flower. Yet, despite long periods of observation, days and weeks went by without my seeing a single insect as much as pause at the sight of the beckoning flowers. My patience was finally rewarded, however, one hot and sultry July afternoon when I saw a small bee in the act of burrowing headfirst between the lips of a flower. I watched this insect emerge covered with a whitish dusting of pollen and then fly off to other flowers where it repeated the process.

Subsequent observations showed that these bees (family Halictidae) fly only on the hottest of midsummer days. Knowing that the petals of dwarf snapdragon wither and fall to the ground within twenty-four hours of opening, I reasoned that these insects must pollinate only a very small proportion of the flowers that open during the whole summer and that self-pollination must be the most frequently adopted mode in this species. To test the ability of dwarf snapdragon to self-pollinate, I tied small muslin bags around several flower buds, thus denying access to would-be pollinators. I removed the muslin bags after the petals had withered and become detached from the ovary of each flower. Flowers treated in this way formed mature seeds indistinguishable in all respects from those produced by untreated flowers, evidence that successful self-pollination can occur. Thus, dwarf snapdragon has the best of both worlds. When growing alone or in the absence of insect visitors, an individual plant can pollinate itself. With the aid of bees, the plant can also exchange pollen with other snapdragons, a less reliable method of reproduction in this species but one that insures genetically variable offspring.

While this article was in preparation, I learned that the railroad line where I carry out my research is to be closed in the near future. Although the railroad enthusiast in me laments this shutdown, as an ecologist I see a rare opportunity to study the changes in vegetation on the cinders in the absence of maintenance activities. What will become of dwarf snapdragon along this line? I predict it will be outcompeted by other annuals and by perennials as the railbed becomes more and more overgrown. Thus, the snapdragon may vanish from an area in which it has held on to a precarious existence for many years. I will miss this little plant even more than the trains that spread it so effectively. □

Jay Maisel

I'd Rather Be a Messenger

New York City's bicycle messengers prefer the independence and excitement of dodging traffic to the routine of a nine-to-five job

by Jack M. Kugelmass

photographs by Yoav Levy

"I'm speeding across town, weaving in and out of traffic. I've already done sixteen runs. Good messengers do twenty-five, but I'll settle for twenty. I'm tired, and it's late. But I'm trying for that magic number. So I pedal harder. I'm pushing, trying to reach the front of the line of traffic. As I move up to take the lead, I no longer feel tired. My mind is working fast, checking out openings. I hug the curb, keeping clear of the traffic. But I'm riding too close to construction debris: there are mounds of dry cement powder on the road. Before I realize what's happening, the bike skids out of control. I pump the brakes but still can't keep my balance. I can feel myself going down. The impact on the cold pavement overwhelms me. I remember there is a truck behind me, but my body won't move. My head can turn, so I twist it backward and stare helplessly at the driver seated high above me. I feel like a conquered gladiator. The driver motions to me to lie still,

not to move until I'm ready. The shock passes. I pick myself up unsteadily and walk my bicycle over to the curb. Still shaken, I get back on and begin to ride, a little slower, a little less arrogant, no longer trying for that magic number."

So ended my first week as a bicycle messenger. I took the job in order to study bicycle messengers, but after a day or two I had become more concerned with magic numbers than with researching the story. Although it made me hesitant to continue riding, the accident on the cement powder put me back on the right path: I began to concentrate on meeting and arranging interviews with other messengers. I also began to understand the attractions of "messengering" as a way of life, particularly the romance of danger.

The 600 bicycle messengers who ply New York City's Borough of Manhattan are a diverse group of people. They cross over class, ethnic, and racial lines, and although a small minority, there are women riders too. But all share a kinship with the heroes of the Wild West. They are romantic adventurers who prefer the exhilaration of danger to civilization's deadening routine.

The streets of Manhattan are a frontier, a no man's land. In the main business districts, they interrupt the flow of civilized behavior, contrasting with the sterile, almost hermetically sealed world of high-rise offices. If there are laws regulating New York City traffic, they are barely enforced. Bicycle messengers are fast and contemptuous of the rules. They intimidate pedestrians and alarm the drivers of other vehicles competing with them for space on the road. Messengers sometimes wear outlandish clothes that go well beyond what is functional attire for riding in town. Some wear gas masks to filter out particles of dirt from automobile exhaust fumes. Others wear special racing gloves from which their knuckles protrude in a vaguely menacing way. And they all have one identifying mark—an oversized bag slung behind their backs.

Bicycle messengers consider themselves part of an elite. Their sometimes stimulating and often hazardous work puts them in a different class from Manhattan's thousands of foot messengers, who are mostly unskilled youths, mentally impaired persons, or older men, past retirement age.

Speed and maneuverability make the bicycle messenger an indispensable part of New York City's most time-conscious and competitive industries—film and advertising. The public at large, however, gives scant recognition for the service they provide. Because messengers generally look scruffy, people respond to them accordingly.

Working conditions in the industry do not support the bicycle messengers' sense of their elite status either. Messengers are independent contractors. They are not eligible for vacation pay, unemployment compensation, or acci-

dent insurance. Some messenger companies blatantly miscalculate paychecks. They refuse to compensate the messenger for dispatchers' errors or they penalize riders for lateness.

Despite the drawbacks, the pay can be good. Although many messengers make less than $150 per week, good ones earn close to $250, and ace riders earn $350 or more. At least one rider, by nibbling nuts and dried fruits throughout the day and seldom stopping to rest, makes $500 a week. Good messengers do close to twenty-five runs per day. Most earn $2 per run, or about half the gross fee. Rates vary according to the distance of the run, the size and weight of the package, and whether the client requests a "rush," that is, immediate delivery.

Part-time riders are almost always docked 5 percent of their week's earnings for each work day they are absent. Thus, a rider who works one day a week receives as little as 30 percent of the delivery fee. Messenger companies encourage part-time riders, both to guarantee enough personnel to handle the volume and to lower the base rate. But the good riders, particularly the ace riders, are given preferred treatment. They receive a higher percentage of the gross and they get the most profitable runs—those that are shortest and closest to one another. At least one company tries to minimize the exploitative aspects of the industry by providing a flat rate of payment that applies to all riders. This company also provides compensation for job-related injuries and gives carte blanche to its riders to talk back to difficult clients.

Using a client's phone, a messenger checks with his dispatcher to get additional assignments. Messengers are often selective, since they profit most if the runs are close together and can be combined.

Earning a good living at messengering is by no means easy. Despite a frenzied effort on my part, I was consistently unable to earn anywhere near the middle or higher income range that the better messengers earn, so I quickly abandoned any idea of messengering as a career. My age (thirty) was not a factor. Although most messengers are in their twenties, some of the better messengers are in their thirties, and a few are in their forties, fifties, or sixties. Most people who become bicycle messengers do so because they are desperate for a job, and they give the work up after a short while just as I did. Only a small proportion continue to ride on a long-term basis.

Long-term messengers share certain character traits in common. Like the heroes of the West, they are mavericks, resentful of conformity and rebelling against it. Often, they are loners who have run into trouble while pursuing more conventional careers. For them, the excitement of bicycling helps to counter the reality of defeat.

Andy is a former psychiatric social worker who abandoned his career after his plans for improving home care for patients were thwarted, he felt, by his coworkers' lack of motivation. Andy's boss, Hank, lost his job doing quality-control research because of his disagreement with the "proper" corporate attitude. Both maintain they are unable to deal with situations that require submission to authority:

HANK: I never got along with bosses. Even when I get along with them, I never really get along with them. I always think of myself as an amiable, compliant, even somewhat passive person. But conflicts inevitably arise.

ANDY: By the way, forget it.

HANK: I'm not amiable? I'm not compliant? I'm not passive?

ANDY: No, you're amiable. But you're neither compliant nor passive by any means, and you know it.

Hank began working as a messenger at age forty-two. Today, eight years later, he is the owner of a rapidly growing

A bicycle messenger delivers reels of film for processing. Indispensable to such time-conscious industries as film, advertising, and publishing, messengers must learn to cope with clients' anger over late delivery.

messenger company. It is one of the few companies that are highly regarded by messengers. Hank treats his riders well, and although he frequently complains, he tolerates their eccentric or even erratic behavior, largely because he identifies with it. Andy is less tolerant of the nonconformism. His frustration results from his attempt, while working at another messenger company several years ago, to organize a union. He concluded that messengers have an almost religious devotion to their independence:

> I became convinced that if you told four bicycle messengers that they would each get a thousand dollars if all four of them showed up at a particular street corner at a particular hour, thereby producing a community experience, you could be damn sure that they wouldn't be able to do it. That they would *not* do it.

Sometimes messengers have left former careers for reasons other than personality conflict. Donald, a 41-year-old messenger, is able to support his wife and 15-year-old son on his earnings. Donald was a film processor, but abandoned his profession because, as a Jehovah's Witness, he could not condone the role he played in producing pornographic material. As a messenger, not only does he feel his conscience is clear but he can also leave work at his own discretion to devote more time to proselytizing for his creed.

Messengers relish their independence: "You basically don't have to answer to anyone." One former messenger, who now works as a graphic artist for a small publishing company, misses her previous life style: "When I go down the street, I'm jealous of the messengers. It's really a lot of freedom."

Although taxi driving is a common occupation of many New Yorkers who are unable to find work in their fields, bicycle messengers find the idea repugnant. They dread the loss of freedom and maneuverability. They take special delight in their ability to weave in and out of traffic, ride the wrong way down one-way streets, and cut through the bottlenecks that regularly stall midtown traffic. Bill, a former doctoral student in experimental psychology, compares the skills for messengering to those needed for slalom skiing:

> There are a lot of things involved in moving quickly and watching the road surface and watching cars and avoiding cars. Of course, you have to react to all these things as soon as they happen, as quickly as possible. And that involves timing and slowing down and braking and so forth. And cadence, of course, that's very important. And you're reacting to the traffic—you have to look ahead and kind of predict where openings are going to be and where are the best places to go.

Traffic is not the only challenge messengers must face. Bicycle messengers are usually given several runs at a time. Although the dispatcher tries to assign runs that are relatively close to one another, the messenger must decide the best pickup-and-delivery sequence, calculating the seemingly illogical system of avenue addresses. Messengers have to think ahead and plan the fastest possible route through the maze of one-way streets. If a package is delivered late, it is the messenger who receives the brunt of the client's and the dispatcher's wrath.

There is also skill involved in maintaining the bicycle. Messengers consider their bicycles to be tools, and many devote time and effort to drying them after a rainstorm, cleaning off excess grease, and overhauling moving parts. Some have an almost spiritual relationship with their bicycles.

In the course of my work I saw dozens of messengers on track bikes: ex-

Messengers are proud of their role in the city's bustling economy. An increasing number ride stripped-down track bikes for an added sense of accomplishment.

tremely lightweight racing bicycles that have been stripped of all excess parts, including brakes, gears, and derailleurs. Because the rear wheel of a track bike is "fixed"—so that the wheel and the pedals always turn together—these bicycles are commonly known as "fixes." They require a good deal of muscle power to ride and even more to stop because braking is done by checking the forward thrust of the pedals. Track bikes seemed ill-suited for frequent stops and starts, so I was curious why messengers would ride them. To find out, I often had to weave in and out of traffic at breakneck speed, trying desperately to keep pace with speedier riders while screaming at the top of my lungs to catch their attention. I caught up with Zowie, a 23-year-old former recording technician, during a winter rainstorm. Like many others I spoke to, he favors the track bike because he feels more in harmony with it, more a part of the bicycle. Abdullah, a young black Muslim, uses Zen concepts to underline the value of riding a "fix":

It's hard. It makes your life harrowing every day. It's part of Zen. You push. You flex and you push. And you tense. You realize that you're keener after you've been through it. You're a bit keener and a bit swifter and a bit more relaxed about what just might come at you in life.

One of the most difficult tasks of messengering is to maintain an element of self-control. Bicycle riders are extremely vulnerable and cannot withstand even the slightest contact with a car, let alone a serious collision. Given the difference in weight between cars and bicycles, there is no point in forcing a confrontation, no matter how provocative a taxi- or truck-driver might be. Like Abdullah, Joe believes that the control that messengers exercise has its wider applications:

It carries over into your regular life with people. You're able to watch people. You know what's developing as they're speaking to you. And you see the reasons behind it. And you don't just react to it. You digest it and get to the reasons behind it, and talk rational.

Messengering is mentally as well as physically demanding. Messengers learn to keep an inner core of themselves alert and aware regardless of what they are doing. They develop a sixth sense for when to focus all of their attention on the road.

Despite the apparent risk, the use of drugs, especially marijuana, is a common feature of the messenger industry. Overhearing a conversation between two riders about obtaining some hallucinogenic mushrooms, I asked them whether getting stoned on the job created any problems. Both felt that the most serious problem was the tendency to get confused and either mix up addresses or forget a destination altogether. Another messenger joined the conversation, stating that although when he first started riding, he would not use drugs, he now believed they have beneficial effects. He described how his attitude changed:

So here it is, Friday morning, everyone's getting paid, and whatever their bag is, they're getting stoned. That was the first time I got stoned, you know, on the job. . . . I remember getting on the bike, riding on the sidewalk. There's a canopy on the block, and I rode between the poles of the canopy into the street, and I felt like I was entering an arena. And all of a sudden, everything that I learned the past month—I wasn't even thinking along these lines—all of a

sudden, everything I learned came together for me, all the traffic patterns and everything else. I had no objection to getting stoned on the job after that.

Even without the stimulation of drugs, messengering is seldom boring. The city is constantly changing, and the people who live within it are always on the move. There is also an element of chance that determines the number of runs, the location of the pickups, and the routes to the deliveries. Riding itself provides a constant thrill. Greg, a thirty-year-old actor trained at the Juilliard School, loves the speed:

I can get up to forty-five miles per hour down Second Avenue. It's a very pure feeling, getting into the groove of riding, where you know that you're on the road keeping pace with all these big machines that can kill you. All you have on your side are your ears—it's a very aural job, because you hear what's happening behind you. And you just know because of your speed and your skill, you can keep up with the cars and cabs and buses and get there faster than anybody. That's great. That's satisfying.

Messengers who live outside Manhattan often cycle to and from work each day. Most of them enjoy riding. As one puts it, "It sure beats working for a living." Another, David, is nearly effusive:

On a good day, you know, there are actually times when I almost whistle while I'm working. I'm so pleased with it, I'll say to myself, "You know, I'm riding around town. I can't believe they're actually paying me to do this. I'm getting exercise, the sun's out, and there are people sitting inside offices wishing they were outside."

The experience of joy from work contrasts sharply with the deadening quality of most work in our society. Perhaps it comes from experiencing the world directly, rather than through an office window or a car windshield. As Joe explains:

You get to greet the morning. There are all these different angles of life. I mean, the city's beautiful. You watch it change. It's a question of stone canyons. The light plays on them, and it's different light all day. You know there's a real connection with being alive, especially when you're coming out of the offices.

Messengers have a sense of superiority over most people they come in contact with, particularly office personnel:

You get a lot of secret envy, you know. They think you're a little crazy in bad weather, but you're free at the same time because you can stop and get off any time you want. A lot of times you're getting treated very poorly by someone, but in the back of your mind, you know you're making more money than they are. And you're probably happier in what you're doing than they are.

Long-term messengers are seldom lacking in other skills. They tend to be opt-outs rather than dropouts. Among them are Ph.D.'s and professionals, such as social workers, writers, and musicians. They are often people who are seeking other than nine-to-five jobs or are unable to fit the regimen of professions for which they trained. They have in common an uncertain future and often a past in which failure figured more prominently than success. For the latter group in particular, riding has become an important source of pride. Initially bitter and angry at not having achieved success in their careers, they find relief in the physical aspects of messengering. Cycling whips bodies into shape. "It has a sort of narcotic effect too," Hank explained. "It drains away inner anger and frustration. It's very hard to be angry when you're physically exhausted."

Messengering also offers an opportunity to complete a job: "One thing about physical work—it's real." Those who turned to messengering from academic work experience particular de-

David writes up delivery tickets before setting out on his bicycle. With a Ph.D. in political science, he is one of many people with academic backgrounds who take delight in the simple tasks of "messengering."

light in doing a simple task—making a delivery—and never feeling that it somehow could be done better. David was a student of political science when he turned to messengering to support himself. Today he has a Ph.D. from Columbia University, and he publishes academic articles on psychohistory and totalitarianism. But he disdains university work:

I did this one library job at Columbia where I was correcting conference papers. And I always had guilt feelings about the job because I never felt that I was doing it right. There was always more I could do. Whereas messengering, you pick it up and you deliver it. That's it. It's over.

Nonacademic types, such as Joe, also appreciate the detachment from responsibility:

I feel in sync with it, if you can call that satisfaction. I don't feel anything emotional at all. It's simple, it's like a very simple process: bing, bing, bing, that sort of thing—like a pinball machine, bouncing off the thing. Bing the right thing, racking up the numbers; that's exactly how I feel.

Remaining calm despite aggravation can be difficult for those who consider the job a step down from a previous position. My own sense of resentment at being treated as a messenger by clients made me all too ready to use my title, Dr., as a weapon, to shock the people I was serving. When I asked David how he dealt with the problem, he agreed that his own career expectations had, at first, made him sensitive to possible slights:

The thing I found about messengering is, if you let things like that get to you, you screw up. It's dangerous. It's literally dangerous. You start thinking about it. You start talking to yourself, and that's when you lose concentration riding and you have accidents. So I found that I really have to "swallow bitterness," as the Chinese say. And I do it pretty well. I'll talk to myself, you know, for the length of time it takes to get down the elevator, and then I wipe it out. I go on to what I was doing before. I find that if at the end of the day I made a decent amount of money, it's all forgotten.

The possibility of death is never far from the minds of bicycle messengers. Most long-term riders have seen other cyclists seriously injured on the road. Although he dismisses the gravity of most injuries, Bob, the manager of Hank's messenger company, says there are two kinds of cyclists—"those who have gone down and those who are going to go down." The danger might be lessened if cyclists wore helmets, but few messengers will do so. "I have to admit," one messenger responded, "I see people wearing helmets on bicycles, and I feel sort of contempt for them. A snickering contempt." For some, the refusal to wear helmets is like wearing an elite uniform. It adds drama and excitement to life, and it does so by emphasizing the nearness of death.

Every once in a while a truck comes out of the shadow. I don't know where from, but it almost takes my life. And you know, it's interesting—it's nice to feel alive again. You get that rush. You look at the sky, and you realize you could have cashed in your chips right then and there. It's a nice feeling. It's like being on the edge.

The sense bicycle messengers have of being an elite probably has a lot to do with the danger they face. They are like the pony express riders of yesteryear. For some, jumping a light is like a daring dash across the plain to the mountain pass. Even the weather plays a role in shaping their image. Long-term riders see themselves more in harmony with the weather than battling against it.

Bad weather sets the stage for the heroic aspects of messengering. "The worse the weather, the better," says one messenger. "Snow is better than rain." In bad weather, the hero-messenger is in great demand. "Somebody's got to do this stuff," says David, "and if I wasn't doing it, there wouldn't be anybody to take my place." David's most heroic moment occurred several years ago when the city's surface transportation system was virtually paralyzed by snow:

There was one other bike along the road. I had to take three or four runs down to the Battery [Manhattan's southern tip]. I got down to the Battery, and it was like Antarctica. Nothing was visible, and the snow was drifting four to five feet. Finally, I began to try to come back uptown, up Third Avenue—it's called the Bowery down there. And I just said, "Screw it!" and collapsed into a snow drift. I was just going to go to sleep and die. Fortunately, a man in a snowplow came along, and he saw me waiting there and he motioned to me. And I just followed behind him back to midtown. It was really lucky.

On Friday evenings I would sit in the basement of Nathan's Delicatessen on 43rd Street and Broadway and trade stories with other messengers. One Friday I sat drinking beer and massaging the toes that I had twisted in a fall from my bicycle several hours earlier. I was worried about my tape recorder, uncertain how well it had survived the fall, and I was worried about myself, uncertain how much longer I could face the hazards of riding. Cochise, a long-haired hippie type, sat at the opposite end of the table eating a bizarre combination of packaged health food and garishly colored pink cotton candy. His jaw still bore the scar from a fracture he received in a collision with a taxi. I had heard about Cochise from the other messengers. I introduced myself, and he responded by pointing to his sockless feet—his trademark. "Why don't you wear socks?" I asked, horrified by the thought of riding in winter without them.

Able to weave through traffic at high speed, bicycle messengers derive satisfaction from competing with heavy vehicles. The dangers of street traffic and poor road conditions add tension and excitement.

I don't like socks. I don't like putting them on. I don't like taking them off. I don't like going through them in the morning. I don't like buying them. They rip. They shrink. They pull. You sleep overnight somewhere, you got to put the same pair on the next morning—ugh. You wear them overnight—ugh. And another thing: No matter how damn cold it gets, no matter how high the snow is, it's a little bit of summer. I'm not wearing socks, man. You understand? It's a little bit of inner strength too.

Perhaps a need to show inner strength has its roots within a deeper sense of defeat. Messengers are generally acquainted with defeat before they become messengers, and their vulnerability to cars, mechanical breakdowns, bad weather, and company mistreatment makes them continually familiar with it. But messengers also have a sense of victory, a sense fierce enough that once it is achieved, they will not part with it. "Do we all like going to work every day?" Cochise asked, determined to put an end, once and for all, to my questions.

We don't all like going to work every day. It's something you gotta do. I just look around this restaurant. There's not another job anyone has in this restaurant that I would want. You take me outside. Look up and down the street. All these people got occupations that they're doing, right? All right, some of them are just walking by, we don't know what they're doing. But you show me just about anyone who's working out there. I don't want any of their jobs. If I gotta work, I'd rather keep this. □

THE MARKET

Art

AMERICAN INDIAN CRAFTS: Pueblo pottery, Hopi 2nd and 3rd Mesa plaques; Kachinas; old and new rugs. No catalogue. One-of-a-kind pieces; individually photographed. Most priced $100/up. Write for photos and data, specifying interests. Box 5896, Sherman Oaks, CA 91413 (213) 789-2559

At last—an efficient woodstove beautiful enough for your home

The WESO Ceramic Tile Stove enhances the beauty of the most tastefully decorated home, where a black metal heater would be rudely out of place.

You can see the flames flickering behind the wrought-iron style grille as the WESO — which employs both convection and radiant heat — surrounds you with gentle all-over warmth.

The WESO burns both wood and coal, holds a fire all night without tending, and offers every efficiency feature you could ask for. Now available in your choice of seven decorator tile colors.

Enclosed is $1. Rush me your literature showing the WESO CERAMIC TILE STOVE in all 7 tile colors — plus details about WESO's new COAL BURNING STOVE — and shipping schedule

Celestial Events

by Thomas D. Nicholson

The Moon The early crescent moon shows up about the 2nd, and provides several interesting evenings as it moves toward Jupiter and Saturn on the 3rd and toward Spica on the 4th. It will be back in the same part of the sky from August 30 through September 1, when Venus is much closer to Jupiter. The late crescent moon passes below Mars in the morning sky of August 26. Phases in August are: first-quarter on the 7th, full on the 15th, last-quarter on the 22nd, new moon on the 29th; in September, first-quarter is on the 6th and full moon on the 13th. Apogee (farthest from the earth) is on August 8 and September 5; perigee (nearest the earth) is on August 21 and September 16.

Stars and Planets There will be seven planets in the evening sky: Mercury (after the 10th), Venus, Jupiter, Saturn, Uranus, Neptune, and Pluto. In the morning sky, there will be two: Mercury (until the 10th) and Mars. The sun moves from the constellation Cancer to Leo on the 10th; Mercury enters Leo in early August and Virgo late in the month; Venus moves out of Leo into Virgo on the 12th; Mars spends most of the month in Gemini but moves into Cancer on the 20th; Jupiter, Saturn, and Pluto are in Virgo; Uranus is in Libra; and Neptune is in Ophiuchus.

The best sky show this month is in the west just after sundown, where Jupiter, Saturn, and Venus are gathering just west (to the right) of Spica in Virgo. Watch from about half an hour after sunset until dark. Venus appears first—very low but very bright—followed by Jupiter, then Saturn and Spica. Early in the month Jupiter is close below Saturn, Spica is to their left, and Venus is about the same distance to their right and below them. During the month Jupiter separates slowly from Saturn, Venus moves rapidly toward them, and all three planets move toward Spica. By the end of August, Venus, Jupiter, and Saturn are lined up horizontally in the west and Venus has moved between Jupiter and Spica. The show will be especially interesting on August 2, 3, and 4, and again on August 30 and 31 and September 1, when the slim crescent moon is in the western sky after sundown.

Jupiter, Saturn, and Venus are prominent features of the evening sky all month in the constellation Virgo, midway between its brightest star, Spica, and Regulus, in Leo. In early August, Jupiter (the brighter) and Saturn are close, Venus is below to their right, setting earlier. By the end of August, all three are in the positions shown, half an hour past sunset, joined by the early crescent moon.

Helmut Wimmer

August 2: With a little luck, you can see the waxing crescent moon in the early twilight sky, brightly shining Venus is below it.

August 3–4: The moon is to the right of Jupiter and Saturn on the 3rd, to their left on the 4th.

August 9: The reddish star below the gibbous moon is Antares, in Scorpius.

August 10: Mercury is in superior conjunction, in line with the sun and earth but beyond the sun and entering the evening sky.

August 10–14: Look for the Perseid meteors any morning after 2:00 A.M. They will be best on the 12th, when you can see 50 or more shower meteors per hour, many of them bright, even bursting. Expect half as many on the mornings before and after this reliable shower, the most plentiful of the year for Northern Hemisphere viewers.

August 23: Mars, climbing sharply into the sky after rising before dawn, passes below Pollux and Castor, the "twin" stars of Gemini.

August 25–27: Venus passes below Saturn on the 25th, below Jupiter on the 27th, and then moves to the east (left) of both. The three planets will be exceptionally close to one another for several nights, but they set at about the end of evening twilight.

August 26: The waning crescent moon joins Mars, Pollux, and Castor in the morning sky. Look before dawn.

August 30–31, September 1: The early crescent moon passes above Saturn about 8:00 P.M., EST, on the 31st, above Jupiter five hours later, and above Venus during daylight on September 1.

September 6: Venus has been separating from Jupiter and Saturn, approaching the star Spica. This evening it passes above and moves to the left (east) of Spica. Jupiter and Saturn, to the right of Venus, set in the twilight.

September 10–13: Mercury, Venus, Jupiter, Saturn, and Pluto are all in the constellation Virgo, and the sun enters the constellation in a few more days.

September 13: Tonight's full moon is the harvest moon.

Editor's Note: The Celestial Events Sky Map in the July issue shows the evening constellations and stars for this month and gives the times for use.

"Rich...exciting...it's an adventure in itself."*

Over 300,000 Americans have tested their physical and emotional limits in the classic programs of Outward Bound. Now, *Outward Bound USA* tells the utterly unique history, philosophy, and lore behind this "aristocracy of service throughout the free world." (Sargent Shriver) "Rich in anecdotes and exciting...this book is also serious and important reading." —*William E. Simon

Representing Earth

by Richard Edes Harrison

THE MAPMAKERS, by John Noble Wilford. *Alfred A. Knopf, $20.00; 414 pp., illus.*

The Mapmakers is a comprehensive account of man's attempts to measure and depict our surroundings throughout the ages. The author has tackled this very complex subject successfully, but it should be said at the outset that the book concerns itself more with measurement (surveying) than with depiction (mapping). And it is not until one is halfway through this 200,000-word book that a clear distinction is made between the two. As a practicing cartographer for fifty years, I do not object, however, because in this case surveying is certainly the horse that is dragging the cart. The title, however, is misleading, and my guess is that the publisher figured it would be easier to sell a book about maps than one about surveying. He may be right, but to many readers, any work in the field—on land, on the seas, in the sky, or in interstellar space—is far more interesting than work on a drafting table, especially now that the drafting table is threatened with displacement by computers. So let us say that this is a book about surveying because surveying is still going strong.

Land measurement today involves the use of a bewildering array of instruments, but primitive humans had only their eyes to see with and their legs to measure with. With the acquisition of a measuring stick, mankind was on the way to sophistication. Many early cultures, such as the Chinese and the Maya, speculated about the earth, the sun, and the universe, but it was the Greeks who were on the right track. In the sixth century B.C., Pythagoras maintained that the earth was a sphere and his contemporary Thales actually predicted an eclipse of the sun. Two hundred years later, influential men such as Plato and Aristotle established the sphericity of the earth by direct observations: for example, of departing ships that seemed to sink below the horizon instead of getting smaller to the point of disappearance, of the curve of the moon's or Earth's shadow during eclipses, and of the new stars that came into view as one traveled south.

In the second century A.D. Claudius Ptolemy of Alexandria wrote two books, *Almagest* (on astronomy) and *Geography.* These were extremely useful as a collation of existing knowledge on these subjects, but in the process the author made two errors that persisted in damaging his reputation forever. First, he rejected the astronomer Aristarchus's proposal that Earth rotated about the sun in favor of Aristotle's Earth-centered universe, and second, he rejected Eratosthenes' measurement of Earth in favor of a much too small estimate by Poseidonius. He did, however, postulate many rules useful to later surveyors and cartographers. For example, he insisted that all maps have a grid, he invented the term *meridian,* and he recommended dividing the latitudes and longitudes into degrees instead of fractions, for which we are all grateful. He defined the scope of maps accurately and said they should be "in just proportion," that is, in scale. At this point the author interpolates a short discussion of scale that requires emendation. I quote: "Sometimes, particularly on road maps, scale is explained with a small ruler near the bottom of the map. This is a graphic scale." A graphic scale, also called a linear scale, is not used just "sometimes"; it is an absolute essential for

any scalable (that is, most median-scale and all large-scale maps) map because it provides the only direct method for making measurements on the map and it is the only form of scale expression that remains true upon reduction or enlargement of the map.

The chapter on Ptolemy is about one of the great keys to cartographic history and its conclusion is appropriate reading for these times.

> If Ptolemy's errors were many, often due to lack of reliable information, the maps based on his scholarship were the culminating achievement of ancient cartography and a crucial legacy. . . . More than a century after Ptolemy, Alexandria became a battleground of revolt and the museum buildings, now over 500 years old, were destroyed. The temple housing the library survived and a few scholars sought to carry on the museum's tradition of research. Finally in 391 A.D., Christian mobs sacked the library, burned the priceless contents and converted the shell into a church. It was a symbolic victory of faith over reason. The words of Claudius Ptolemy, among others, were lost to the Western world for more than a millennium and so too his ideas and ideals for a scientific cartography.

The author then carries us through the Dark Ages, dwelling perhaps a little too extensively on the ignorance, the meaningless mythology and suppression of curiosity while the accumulated wisdom of the Greeks was imprisoned in a few monasteries. The growing waterborne commerce prompted a new start toward exploring the unknown, and by the beginning of the fifteenth century, Henry the Navigator, prince of Portugal, formed the beginnings of a shore-based organization devoted to stimulating exploration and studying the results. Maps are mentioned frequently, but there is relatively little in-

Speak German like a Diplomat!

What sort of people need to learn a foreign language as quickly and effectively as possible? Foreign service personnel, that's who.

Now *you* can make a start on learning to speak German with the same materials used by the U.S. Department of State — the Foreign Service Institute's *Programmed Introduction to German* and *Basic Course, Continued*

The FSI spent thousands of dollars and many years developing these materials for use by members of America's diplomatic corps. Today people in all walks of life who need to learn to speak a foreign language are turning to this outstanding audio cassette program.

The Foreign Service Institute's German Course is by far the most effective way to learn German at your convenience and at your own pace. It consists of a series of tape cassettes and accompanying textbook. You simply follow the spoken and written instructions, listening and learning. By the end of the course you'll find yourself learning and speaking entirely in German! A native German speaker, clearly recorded on the cassettes, provides an excellent model to help you develop your skills.

This course turns your cassette player into a "teaching machine." With its unique "programmed" learning method, you set your own pace testing yourself, correcting errors, reinforcing accurate responses.

The FSI's Programmed German Course comes in two volumes: You may order one or both courses.

☐ **Volume I. Programmed introduction to German,** 9 cassettes, 12 hours and 647-page text, $115

☐ **Volume II. Basic Course, Continued** 8 cassettes, 8½ hours and a 333-page text, $98

(New York State residents add appropriate sales tax.)

Your cassettes are shipped to you in handsome library binders.

TO ORDER, JUST CLIP THIS AD and mail with your name and address, and a check or money order. Or charge to your credit card (American Express, VISA, Master Charge, Diners Club) by enclosing card number, expiration date, and your signature.

The Foreign Service Institute's German course is unconditionally guaranteed. Try it for three weeks. If you're not convinced it's the most convenient and most painless way to learn German, return it and we'll refund every penny you paid! Order today!

formation about their actual drafting or who drew them. I suspect that in the early days drafting was usually done by the skipper, but later on it might have been done by a bright midshipman. And of course the voyager might bring home sketches and notations that a professional would then convert to a map. These gentlemen and their products are not neglected; we learn about Abraham Cresques, Martin Behaim, Gerhard Mercator (plenty about him), Martin Waldseemüller, and the Cassinis—father, son, grandson, great-grandson, and many others.

We also learn about the invention and development of triangulation, the measurement of arcs of meridians (to reveal the true shape of the globe), and the origins of the compass, astrolabe, sextant, theodolite, transit, and a host of other instruments. John Harrison's invention of the chronometer (thereby solving the problem of measurements of longitude at sea) is a particularly fascinating story. In the eighteenth century, in 1779, the Cassinis completed the mapping, by triangulation, of France. In the United States the heroes of surveying and mapping were Mason and Dixon, Lewis and Clark, Powell, Maury, and Ewing.

The first half of the book ends with the international agreement to collaborate on a "one-millionth" (sixteen miles to the inch) map of the world. The second half is devoted to the twentieth century and the astounding inventions that have revolutionized surveying and mapping. These include the airplane, specialized cameras, deep-sea drilling, bathyscaphs, lasers, tellurometers, sonar, radar, satellites, and automated surveying and mapping. This is exciting stuff and well told. Wilford had an enormous amount of homework to do and mastered it handsomely. The only weak spot to my eye is the four-page section on map projections. It lacks organization and misses the interrelations of projections entirely, but it is accurate as far as it goes.

Each of the four sections of *The Mapmakers* is preceded by a short episode of a recent expedition that surveyed the Grand Canyon with the latest gadgetry, including helicopters, walkie-talkies, and a distance-measuring instrument loaded with telescopes, laser beam generators, computers, and so on—price, $18,000. The author was present on this trip as a modern reincarnation of a "chain carrier" (surveyor's assistant), and the experience no doubt intensified his urge to write this book.

He writes appreciatively about François E. Matthes, of the U.S. Geological Survey, who surveyed the canyon eighty years ago. "He did it by plane table and transit, by foot and mule, by patience and fortitude." After the leader of the recent expedition, Bradford Washburn, an accomplished mountaineer and explorer, had completed his calculations one day, he remarked, "It is surprising how closely the new data agrees with the older surveys of the Grand Canyon." The helicopters and the distance finder certainly saved an enormous amount of hard work and time in this survey, but I am sure that the innovators will not be satisfied with this. The next development may be a completely automated surveying and mapping plant on an airplane, which will deliver finished and printed maps upon landing. In this scheme two important things will be lost, the pride of workmanship and the role of judgment in map design. This is sometimes called Art and is unknown to computers and most engineers. Will we be smart enough to avoid this pitfall?

The above review was written on the basis of an advance copy consisting of bound page proofs, without an index, illustrations, bibliography, or notes. A bound copy arrived too late to make changes but the following information may be useful. The book now has fourteen pages of bibliography and lists of persons interviewed arranged by chapters—a most impressive feature. There are a good many illustrations, intelligently selected but surprisingly uneven in quality. For example, a Landsat photomosaic of New Jersey is sharp and clear, but the Landsat photomosaic of the entire United States is murky and almost unreadable. The first picture in the book, however, is a stunner of the author and a surveyor on top of an extremely perilous pinnacle in Grand Canyon. Makes me shiver.

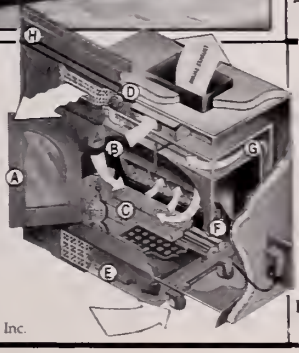
There is one rather embarrassing error: on page 299 it is reported that geologist Bruce Heezen received the Buchler Medal from "The American Geographic Union." On a hunch, I called the American Geophysical Union in Washington, and it is indeed this group that awarded Heezen this richly deserved medal.

Richard Edes Harrison, who has been described as an "explanatory" cartographer, is the first and only holder of the O.M. Miller Medal for Cartography and Geodesy awarded by the American Geographical Society in 1968.

Pentax binoculars separate the bird from the bush.

A Bittern sits motionless, challenging you to pick him out from a background that seems to match him perfectly. Now you need the razor sharp optics, high contrast and superb color rendition of Pentax 8x30 Lightweight Binoculars. Fully coated, perfectly matched optics, fold-over eyecups for eyeglass wearers. Lifetime warranty. See the difference at sporting goods dealers or write Pentax Corporation, Englewood, CO 80112.

PENTAX BINOCULARS



Save Your Fireplace!

Those crackling flames can lift your spirits, but your open fireplace actually *wastes* more heat than it delivers. Perhaps you've discovered that tubular grates, glass doors and ordinary fireplace inserts offer only a partial solution at best. Yet a black metal woodstove on your hearth would be an affront to your room decor.

Efficiency on wheels

The Shelburne can transform your fireplace into a super-efficient heat producer without compromising the visual and soul-warming pleasures it provides. You enjoy a visible fire behind safe Corning Pyroceram glass. Downdraft combustion, 2000°F space-capsule insulation and a 40" baffle system help account for its amazing performance. And the Shelburne *rolls out* on your hearth for easy chimney cleaning.

The Shelburne Fireplace-Stove

(A) Doors may be opened to view the fire (B) Air is preheated as it enters downdraft and secondary air tubes (C) Firebrick-lined ¼" steel firebox (D) Automatic thermostat (E) Pullout ash pan (F) Fan with speed control (G) 40" baffling system (H) Flanges in choice of 3 widths permit installation in over 80% of all fireplaces.

Additional Reading

Maya Volcanoes (p. 32)

Based on extensive field studies of many of the earth's important volcanoes and volcanic regions, F. Bullard's *Volcanoes of the Earth* (Austin: University of Texas Press, 1976) presents in nontechnical language current knowledge of volcanoes and their effects on the environment and people. This 579-page text, amply illustrated with photographs, diagrams, and maps, includes a full-color section showing volcanoes and volcanic eruptions in many parts of the world. A summary of the prehistory of Chalchuapa, a major site in the Maya frontier region, R.J. Sharer's "The Prehistory of the Southeastern Maya Periphery" (*Current Anthropology,* vol. 15, pp. 165–87) establishes a basic chronology for occupation at the site and defines the sources of external influences. Sharer also discusses changes in Chalchuapa brought about by the eruptions of Ilopango. "Chalchuapa: Investigations at a Highland Maya Ceremonial Center," also by Sharer (*Expedition,* Winter 1969, pp. 36–38), surveys some of the more significant results of the University Museum's archeological research at El Trapiche, northeast of Chalchuapa. P.D. Sheets's "An Ancient Natural Disaster" (*Expedition,* Fall 1971, pp. 24–31) reconstructs the nature and effects of the second-century Ilopango eruption, proposing that the thick layer of volcanic ash deposited over Chalchuapa rendered farm lands unusable and prompted the emigration of groups of Protoclassic peoples to new areas. Sheets and D.K. Grayson edited *Volcanic Activity and Human Ecology* (New York: Academic Press, 1979), a multidisciplinary collection of twenty articles exploring volcanic hazards and their adverse and beneficial effects on living organisms and the environment. This work includes a chapter by Sheets, enriched by a very useful bibliography, on the cultural and environmental effects of the Ilopango eruption on Central America (pp. 525–64). *Volcanism and the Prehistory of the Zapotitán Valley, El Salvador,* edited by Sheets, will include the work of about twenty authors and cover the volcanic eruptions of the last 2,000 years in central El Salvador. This archeological survey, scheduled to be published by the University of Texas Press, Austin, next year, will contain data from excavations at numerous sites in the Zapotitán Valley, including Cerén and Laguna Caldera. *The Environment as Hazard,* by I. Burton, R.W. Kates, and G.F. White (New York: Oxford University Press, 1978), is a multidisciplinary summation of the whole range of experience associated with natural disasters.

Avocets and Stilts (p. 42)

Even though the large, colorful avocet is a conspicuous, social bird with a wide distribution, it has received little ecological or behavioral study. One good account presenting information about avocet breeding biology, based on research done in the late sixties, is F. Gibson's "The Breeding Biology of the American Avocet (*Recurvirostra americana*) in Central Oregon" (*Condor,* vol. 73, pp. 444–54). Gibson, who observed avocets during three breeding seasons in an alkaline marsh, reports on the birds' territorial system, courtship, nest building, egg laying, incubation, and hatching. R.B. Hamilton's "Comparative Behavior of the American Avocet and the Black-necked Stilt (Recurvirostridae)" (*Ornithological Monographs* no. 17, published by the American Ornithologists' Union, 1975), a summary of the biology of this family that includes detailed descriptions of behavioral displays, is virtually the only published study of black-necked stilt breeding behavior. Hamilton concludes that the numerous morphological and behavioral differences between these two closely related species correlate with habitat differences and probably reflect differences in their evolutionary histories. *The Shorebirds of North America,* edited by G.D. Stout (New York: Viking Press, 1967), contains accounts of species by R.S. Palmer, a popular-style text by P. Matthiessen describing habits and histories of the birds, and excellent color plates from paintings by R.V. Clem. Another general text is A.C. Bent's *Life Histories of North American Shorebirds* (New York: Dover Press, 1962), originally published in 1927 and still a standard reference for avian life histories. Bent's text includes many fine descriptions of behavior, although as noted in the present account, he misinterprets avocet distraction behavior. Two books on predator–prey behavior are E. Curio's *The Ethology of Predation* (New York: Springer-Verlag, 1976), a technical review of the predatory and antipredatory behaviors of animals, and R. Meinertzhagen's *Pirates and Predators* (London: Oliver and Boyd, 1959), a colorful account of hunting behaviors of birds of prey around the world that typifies the "fang-and-claw" approach to biology. "Life at an Avocet Nest," with photographs by M.M. Tremaine (*Audubon,* March 1975, pp. 68–75), is a short, staff-written photographic essay providing basic information about avocets. One of the twelve locations described in *Roger Tory Peterson's Dozen Birding Hot Spots,* by G.H. Harrison (New York: Simon and Shuster, 1976), is the Bear River Wildlife Refuge, one of the two study areas discussed in this issue's article.

Narwhals (p. 50)

"Whether there is or is not an actual unicorn . . . he cannot possibly be so fascinating or so important as the things men have dreamed and thought and written about him," states O. Shepard in the introduction to *The Lore of the Unicorn* (Boston: George Allen and Unwin Ltd., 1978). Originally published in 1930, Shepard's eloquent, illustrated study traces the long history of the legend of the unicorn, beginning with its first appearance in Western literature in the fourth century A.D. Chapter nine, "Certainties" (pp. 253–72), outlines the discovery of the "sea unicorn," the narwhal, and the commercial history of its tusk. A large, informative volume that describes in detail thirty-three species, *The Book of Whales,* written and illustrated by R. Ellis (New York: Alfred A. Knopf, 1980), includes a chapter summarizing basic knowledge of narwhal biology, the effect on the whale of hunting, and whale mortality (pp. 95–100). An illus-

trated text comprising twenty-one comprehensive articles written for scientists and laymen, *Marine Mammals of Eastern North Pacific and Arctic Waters,* edited by D. Haley (Seattle: Pacific Search Press, 1978), contains M.A. Newman's "Narwhals" (pp. 138–44). Illustrated with more than two hundred photographs, F. Bruemmer's anecdotal, personal narrative *Encounters with Arctic Animals,* (New York: American Heritage Press, 1972), relates how they live, are hunted, and have been affected by humans. Bruemmer's informative chapter "The Sea Unicorn," on the narwhal and its closest cousin, the white whale, appears on pages 220 to 237.

Weeds (p. 58)

Although no books deal primarily with railroads as habitats for plants, E. Salisbury's *Weeds and Aliens* (London: Collins, 1961) provides an excellent, readable, and authoritative introduction to the natural history of weeds in all their major habitats. Focusing on the traits of weeds that make them successful colonizers, T.A. Hill's *The Biology of Weeds* (London: Arnold, 1977), number 79 of the Institute of Biology's "Studies in Biology" series, also reports the adverse impact weeds may have on crop plants. J. P. Grime's more technical study, *Plant Strategies and Vegetation Process* (New York: John Wiley and Sons, 1979), outlines the processes that control vegetational structure and composition and discusses the kinds of strategies that allow plants to colonize and flourish in different habitats. No mention is made of railroads specifically, but much attention is given to the special adaptations and evolutionary strategies of weeds. J. C. Kricher's "Needs of Weeds" (*Natural History,* December 1980, pp. 36–45) examines, from an ecological and evolutionary standpoint, the vital role of weeds as colonizers, their high dispersal rates, herculean reproductive powers, and adaptability to rigorous environments. The "Additional Reading" column of that issue (p. 74) describes ten more references.

The Nature Faker

Until her retirement last April, Frederica Leser worked on the top floor of the American Museum in a sunny, cluttered corner of the exhibition studios. She recently returned for a retirement tea, and as she sat at her desk, she talked about her experiences at the Museum. A handsome and direct woman with gray hair and a tanned face, Leser worked as an artist in the Exhibition Department for twenty-one years. Her specialty was painting, with great skill, casts of fishes, amphibians, and reptiles for exhibition halls. Using glazes, washes, metallic paints, lacquers, and oils, she re-created the silvery sheen of salmon, the neon colors of tropical fishes, the warm ochers of pythons and rattlesnakes, the azures and dusty greens of lizards, and the glossy blacks and reds of salamanders.

Leser began painting animal casts for the Hall of Ocean Life and then moved to the Hall of Reptiles and Amphibians. She also built models and prepared artificial leaves, grasses, and other odds and ends for dioramas and habitat groups. Her last major project was painting the murals, frescoes, and complex, interlocking designs in the new Hall of Asian Peoples.

"I did a couple of pythons and most of the other animals for the Hall of Reptiles and Amphibians," she explained. She rummaged through a pile of blown-up photographs and pulled out one that showed her hunched over the cast of an enormous snake coiled about a pile of eggs. "This python was cast live. She was anesthetized and coiled about these python eggs to show how she incubates. I painted every scale many times to build up the color through multiple glazes. If you've ever seen one of these things alive, you know what rich, deep colors they have. You can't just paint the thing once and have it look real. When you're nature-faking, you get a sense of just how beautiful these animals are. They're a tremendous challenge for an artist.

"The twenty-five-foot reticulated python in the hall was the first snake I did. We had an old mounted python that had been around for years, never painted or finished, looking just like a piece of dirty brown leather. When I started painting it, I made several trips to the zoo to get the colors exactly right. I remember one time I wanted to see the color of the belly, and someone brought out a little ten-foot python—they wouldn't let me see the big ones. I'm not afraid of snakes, and I got in very close, a little too close I suppose, and the zoo keepers shouted at me to 'get back!' Apparently these sluggish snakes have a simply dreadful bite, and they strike suddenly and very fast.

"The first big hall I did was the Hall of Ocean Life. I painted 85 to 90 percent of the fishes in the hall, mostly with an air brush. The reptiles require more exact brushwork because they have a precise, hard-edge quality to their coloring. Fishes are softer. They ranged from tiny fish the size of your thumb to the great white shark. Dave Schwendeman, who is the chief taxidermist in exhibition, positioned and cast most of the fishes from preserved specimens. It was Dave who taught me to "see" the animals I was trying to reproduce, to realize their subtlety.

"The colors of live fishes are very beautiful and deep—and difficult to capture in paint. We used a lot of pearlescence and washes and metallic paints to give them those special silvery and shining fish colors. Finding the exact colors to use was a problem. The color leaches out of preserved fish, although they keep their markings. You really need to look at live or freshly killed fishes, since they lose their color so fast. Some colors—I hate to admit it—we had to guess at. All we knew about the Chinese river fish was that they were the color of mud. As you know, mud comes in many colors—brown, red, black, gray, or whatever. We painted our fish brown. With the Chinese delegations touring the museum, we're just waiting to hear how the river fish are all the wrong color. We spent six or seven years painting the fishes in that hall.

Frederica Leser fixes a crocodile's teeth for the Hall of Reptiles and Amphibians

Bergenfield, N.J. 07621

"I started at the Museum in October of 1960. I'd been painting on my own for seven years after college, and I thought it was about time I got a steady job. So I came over here and by God they hired me.

"My first assignment was helping our taxidermist clean the birds in the Hall of North American Birds. We repaired the old mounts, cleaned and arranged the feathers, and I painted the bills and feet. Do you know how to clean a mounted bird? You wash it with unleaded gasoline, sprinkle it with plaster dust to absorb the dirt, and then blow off the plaster with an air hose. I also made 4,000 mangrove leaves. You know that mangrove swamp in the hall—I made all those damn leaves. I would never do that again.

"People ask me how I can have the patience to paint snakes, frogs, and so on. People aren't aware of the beauty of the colors of animals."

Scattered about Leser's desk, lying on tables, hanging on walls, and piled on the floor are many odd things, either artifacts of past projects or bits and pieces of projects under way. Stuck into a block of styrofoam are seven fake dandelion leaves that look perfectly real as close as six inches away. Perched on top of a cabinet is a scruffy hawk missing numerous tail feathers. ("The Ornithology Department wanted to throw it away. We *never* throw anything away around here.") Hanging on a large pegboard are some fifty plaster animal muzzles, one crocodile face, two gorilla feet, one tapir nose, and a fish. ("Somebody wanted to throw these out too. Can you imagine?") Twenty feet from the desk is an osprey nest: a mass of sticks, eelgrass, seaweed, and crab shells hung on a branch. ("Dave renovated the nest and I went to Montauk and collected a baleful of fresh nest material. There were two ospreys, but one disappeared years ago.")

She opened a small cabinet and removed some unpainted casts. "This is a flying lizard from Madagascar or someplace like that. Like a moth, it's attracted to light and it flies into people's

DISCOVERY TOUR TO THE NILE

American Museum of Natural History
Discovery Tours

Discover the world of ancient and modern Egypt on an American Museum 600 mile Nile Cruise. Explore with three lecturers the rich natural and archeological sites of an area which has fascinated visitors for centuries... A carefully planned itinerary (with a special two-day program in London visiting the British Museum with its keeper) provides a relaxing and thorough three-week Discovery Tour. All of the major Nile archeological sites as well as the important wildlife regions are discussed and visited with your balanced team of eminent lecturers. Share with Museum staff and friends an unforgettable cruise. February 9-25, 1982. For further information and itineraries write to the **American Museum of Natural History, Discovery Tours,** Central Park West at 79 St., NY NY 10024, or call (212) 873-1440.

NATURAL HISTORY MAGAZINE BINDER

The functional way to save your full year's issues for future reference and pleasure. "Natural History" stamped in gold color on dark green leatherette over heavy binder's board. 12¾" x 9". Price $6.50. Members $5.85.

Come explore a comet.

Halley's Comet returns in 1985. The Europeans, the Soviets, and the Japanese are readying spacecraft to meet it. Our nation plans to watch from afar because NASA has no money for a Halley mission even though only the U. S. has the technology needed to fully probe this comet for the clues it offers on

the origin of our solar system. We stand to lose not only knowledge, but also new technologies and a bit of our prestige.

Last year 10,000 people used the Viking Fund to show their support for space exploration. They contributed an average of $10 apiece to help one starving project: the Viking lander on Mars.

Now the Viking Fund's organizers announce the Halley Fund. By donating to this new fund, you'll let Washington know you want a U. S. probe of this comet. Your money will help pay for the mission, for Halley studies from the shuttle, and for U. S. participation in the International Halley Watch.

So come explore a comet, but don't delay. Your next chance to contribute to a Halley fund won't come until the year 2062.

THE HALLEY FUND

Dept. NH
3033 Moorpark Avenue, Suite 27

windows at night. Imagine sitting in your living room and having this thing fly in."

Leser was asked about her plans for the future.

"I have a few acres on Long Island," she said, "and I'm trying to get a variance to build a small earth-sheltered solar house using native materials. I'll also get back to my painting, and I'm going to take a raft trip down the Colorado River. I'm interested in all kinds of things."

On her way out, Leser passed a reconstruction of the extinct dodo bird and stopped. "It's being repaired with pigeon feathers," she said. "I love its expression and its purple face. They don't really know the color, of course.

"Working in the Museum has been a wonderful experience. I love the Museum very much; as an entity in itself, as a great museum, and as a repository of incredible collections, it is just fantastic."

Douglas J. Preston

Indonesian Odyssey

During the past decade the richness of Indonesia's natural history and ancient cultural traditions have attracted an increasing number of travelers. The Museum is pleased to offer its members and friends a custom-designed tour that will include the highlights of Indonesia as well as numerous ports and excursions not available on the standard tours usually offered to the public. The *Indonesian Odyssey,* February 21 to March 13, 1982, is based on the Museum's long tradition of expeditions to this remote and beautiful archipelago.

Thomas D. Nicholson, director of the Museum, will head a traveling faculty of five lecturers for the voyage. An anthropologist–art historian, an astronomer, a geologist, a herpetologist, and an ornithologist will provide participants with an in-depth lecture program about this exciting area.

Highlights of the trip include a visit to the Sultan's Palace on Java; a cruise to the islands of Flores, Mai, and Banda to see ceremonies and experience the lush tropical landscape studded with smoking volcanoes; a visit to Komodo Island to study the Komodo dragon; and a stop at Bali, where the late Margaret Mead did much of her research.

The Museum's ship is the m.s. *Regina,* renovated in 1980. Its facilities include three lounges, a gymnasium, a swimming pool and sauna, and ample deck space for sunbathing and reading.

For further information about this tour and other Museum tours, write to Discovery Tours at the Museum or call (212) 873-1440.

Shakespeare Summerfest

The Museum is planning a number of activities in conjunction with the special exhibition in Gallery 3, *Shakespeare: The Globe and the World.* All programs taking place in the Museum are listed here; for other Summerfest Programs, write to the Education Department for a brochure or call the Museum at (212) 873-1300, ext. 227. All programs listed below are free.

Shakespearean Tours and Lectures

Brief talks will be given several times a day in the exhibition, and guides will be available to answer questions. Three longer lectures will also be given every day in the People Center.

Strolling Players

The Summerfest's troupe of strolling players will enact Shakespearean scenes in the Museum and elsewhere during the exhibition.

Shakespeare in Japan

On Saturday, August 1, at 1:00 P.M. in the People Center, the Japanese film *Throne of Blood* will be shown. Written, produced, and directed by Akira Kurosawa, the film is based on *Macbeth.* Discussion will follow.

Shakespeare in Armenia

A program, *Shakespeare and the Armenian Theater,* will be given in the People Center on Saturday, August 8, at 1:00 P.M. There will be readings from Shakespeare's works and dramatizations in both Armenian and in English.

Shakespeare in France

A program dealing with the translations of Shakespeare's works into French will be presented on Saturday, August 22, at 1:00 P.M. in the People Center. This bilingual program will include readings from French poets.

Shakespeare in Combat

A program entitled *Shakespearean Weaponry and Dueling* will be given on Wednesday, September 2, at 7:00 P.M. in the Education Hall. A demonstration of Elizabethan weaponry will be included.

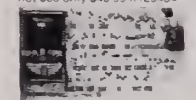
Shakespeare in Italy

The Many Faces of Love: Shakespeare's Italy, a lecture with readings from *Romeo and Juliet, The Merchant of Venice,* and *Othello,* will take place on Saturday, September 5, at 1:00 P.M. in the People Center. Music from Verdi and other Italian composers who were influenced by Shakespeare will also be featured.

The Shakespeare Summerfest has been made possible by support from the National Endowment for the Humanities.

Look what we've brought back from Europe.

Hello, we're back again. This last trip to Europe added so many new titles to our list of imported Classical Music that we'll have to strain your eyes a little with itty-bitty typeface. You know that prices for imported Classical Music can be outrageous. But this can be changed. Here's how we're doing it: We buy large quantities with an ever stronger Dollar. We handle our own shipping. We cut overhead and sell directly by mail. And so our imports often cost far less than you'd expect. All recordings are pressed, printed and sturdily boxed in Europe. All are Stereo unless otherwise noted. All are factory-fresh European namebrands. As many of these sets are available for the first time in the U.S.A., not prices are for comparison only, based on the suggested list price for comparable LP sets.



The Most Beautiful Madrigals. with the Collegium Vocale, Cologne. The listener will discover a treasure. Sung in Ger./Dutch/Span./Fr./Eng./Ital. cond. by W. Fromm. CBS Masterworks (79333). Made in Germany. Text Eng/Ger. ★★★ 3 LPs not $30 only $22.99 lt#29579.

Planter's Lunch

A carpetbagger's kitchen tour of the New Old South

by Raymond Sokolov

North of Charleston, in that swampy paradise for waterfowl known as the South Carolina Low Country, is a 9,000-acre quondam rice plantation I will call Tara. It began as a cypress swamp where Indians fished. Toward the end of the seventeenth century, European settlers discovered that rice would thrive in the murky waters that ran through the plantation to the Atlantic. Slaves who spoke Gullah, the West African–English patois, extirpated the cypress and dug dikes for rice impoundments. The crop was so lucrative that it took two centuries before a combination of hurricanes, competition from more economical rice fields in other states, and Reconstruction brought an end to Carolina riziculture. The *coup de grâce* came in 1942, when hydroelectric damming let seawater flow inland, turning the Low Country into a brackish fen.

By then, certain rich Yankees had bought control of many of the old estates. They converted the impoundments into game preserves and managed the salty water so that it produced food for shootable birds. The only constant in this human-churned environment was the black population. Some descendants of the slave communities remained, while rice mills and whole "streets" of slave cabins collapsed.

One such black retainer was on hand, early in this century, when Tara's new Yankee owner arrived unannounced, landing a private plane in a field. The black servant had never seen a plane before, never heard of one, but he gathered his courage and walked forward to greet the young visitor from the sky. "Hello, Massa Jesus," he said, "and how's your Pa?"

Descendants of slaves carry on the cooking traditions of South Carolina's Low Country.

Today, that man's grandson carries on the family tradition at Tara. He lives by the old and crumbling rice mill, and he speaks Gullah with his wife, who cooks plantation meals in the big house. Her fried chicken is a paradigm of the best in southern cooking. Her hot biscuits define delicacy in baking. When this dignified, taciturn old woman makes crab cakes, they are light and crisp and almost pure crab meat.

Like other traditional Low Country cooks, she uses rendered pork fat from bacon or hog jowl, where most of us would use butter or oil. When she makes shrimp stew, she begins by frying bacon in the pot.

There is nothing more fundamental to a cuisine than the fat it uses. In his classic study of French regional cooking, *The Food of France,* Waverley Root divides France into three parts: the "domains" of butter, olive oil, and lard (meaning any kind of pork fat, as well as goose fat).

In the Old South, salt-cured pork was the standard source of cooking fat, even in seafood dishes. Oysters were prepared this way, for example, in brown oyster stew with benne, or sesame seed (see recipe). Benne was introduced by slaves, who considered it a lucky plant. Modern versions of this Afro-American stew are done, not with cured "side meat" or jowl, but with more readily available bacon.

Oysters continue to be a mainstay of Low Country seafood. At Tara, on special occasions, local gentry gather for an open-air oyster roast. This feast is similar to the New England clambake, but it is far simpler. Indeed, a Low Country oyster roast requires nothing except a fire, a grill, bushels of select McClellanville oysters from just down the coast, and burlap sacks. You dump the oysters on the fire, cover them with burlap, and as soon as they start to open, you shovel them onto a table covered with paper.

Guests are provided with one work glove, to protect the hand that holds the oyster, and an oyster knife, to cut the bivalve loose. I consumed several dozen juicy charcoal-roasted oysters one nippy evening. As if this were not enough, the natural order of things in the Low Country supplies an extra bonus for the omnivorous diner at an oyster roast. Every so often, one of the oysters contains a small, pink soft-shelled crab.

Pinnotheres ostreum, called the pea or oyster crab, is a tiny creature that attains a maximum width of one and a half centimeters. At an early stage, it crawls inside an oyster and installs itself for a lazy, commensal existence. Harmless to its host, the oyster crab merely uses the larger animal as an apartment. Male oyster crabs do migrate in search of a female residing in another oyster. But once the uninvited male visitor has copulated, he dies.

Our forebears prized these tiny shellfish. Alan Davidson, in *North Atlantic Seafood,* reminds us that George Washington loved them so well that *P. ostreum* was almost renamed the Washington crab. The first president often saw them served floating on top of an oyster stew. And in palmier days, Americans frequently ate oyster crabs sautéed or deep-fried, with or without oysters. Davidson also mentions two recipes from a Philadelphia cookbook published in 1901: an omelet containing twenty-five to forty oyster crabs and a "real extravaganza" called Canopy à la Lorenzo, which consisted of a bell-shaped crouton stuffed with fifty oyster crabs, one-fourth of a truffle, crab meat, chicken meat, and cream, all dusted with bread crumbs.

I doubt that anyone in the South Carolina Low Country still serves oyster crab as a separate dish, but the culinary past persists at old homes like Tara because the memory of how to live off local products persists. And the old cypress swamps still produce most of the old-time foods, including a yellow-bellied turtle called terrapin or cooter (see recipe). Certain foods common all over the South—Jerusalem artichoke, mustard pickle, pickled okra—are widely available in Charleston supermarkets. At the gourmet shop in the shopping arcade in Charleston's boutique-filled former slave market, you can buy folkloric, if foxy, wine fermented from the juice of the scuppernong grape.

Meat counters routinely sell shreds of bacon for rendering. And the local predilection for rice has more than survived the demise of South Carolina's own rice production. Local cookbooks are filled with recipes for pilaus: elaborate risottolike dishes garnished with okra, chicken, or shrimp. The prevailing local pronunciation of pilau, no doubt a Gullah adaptation, sounds like "perloo."

So Low Country cooking traditions are not all shriveling up in the face of competition from the master culture. But culinary tradition in and around Charleston can only be as vigorous as the people who cook it. And eat it.

The ideal mode of transmission of traditional food knowledge is from an expert cook to an apprentice living in the same household, under culturally and agriculturally stable conditions. This perfect set of circumstances obtained in the South in general, and on

The superb plantation cook, left, probably the last in her line, made a shrimp stew for the oyster roast, above.

large southern plantations in particular, for generations. Even after Low Country plantations were sold to Yankees during the "Second Reconstruction" following the 1929 stock market crash, kitchen staffs still carried on the practices of their mothers and grandmothers. Only a generation ago, there were still blacks at Tara who had never set foot off the property.

Today, the Tara cook is probably the last in her line. And even her cooking shows signs of a corrupting contact with the outside world and its convenience foods. Her shrimp stew, for example, contains bottled ketchup, Texas Pete hot sauce, and Lea and Perrins steak sauce.

In Charleston, the same discontinuity is detectable even in places where tradition is most militantly affected. For example, the local Junior League cookbook, *Charleston Receipts,* includes old-fashioned cooking terminology, but a woman on the committee responsible for the book told me that she didn't understand expressions such as "a blade of mace."

Actually, it is a good thing that the texts of these recipes, with their antique references to blades and pecks, have been scrupulously preserved. The honest scribes at the Charleston Junior League have reproduced on paper the practice of their mothers and their mothers' cooks without so much as a phrase of modern revision. But how much longer the women in Charleston's stately and well-kept homes will continue the New Year's Day tradition of cooking Hoppin' John, that hearty combination of rice and cowpeas (small legumes, also called field peas, resembling miniature black-eyed peas) is not clear. The dish, which gets its special flavor from rendered hog jowl or bacon, dates back at least as far as 1841, when, according to oral tradition, it was hawked in the streets of Charleston by a crippled black who identified himself as Hoppin' John.

This superb concoction will continue to stick to Low Country ribs as long as someone keeps on growing cowpeas, as long as there is a demand from those astute enough to crave this savory source of complete protein. Other aspects of South Carolina Low Country cooking are more fragile, more dependent on social context and culinary skill. I have in mind the lunch that took place after Tara's most recent oyster roast.

Inevitably, some of the roasted oysters were left over. With consummate delicacy, the old cook breaded them lightly and fried them. They came out crisp, but still succulent and full of the smoky taste from the previous night's outdoor feast.

At Tara, they can still pull off this sort of culinary magic, but Tara is a special place, costly to maintain. It is also gravely menaced by a plan to redredge neighboring rivers, which will desalinate Low Country rice impoundments and make them unfit for supporting the carefully nurtured plants that attract the game birds that currently attract wealthy Yankee owners. The trend, in any case, is for such Low Country plantations to be donated to the public as nature conservancies. In one such 20,000-acre tract that I toured, the endangered red-cockaded woodpecker finds a safe niche, and a protected herd of deer feed on corn set out for them in troughs. The former black staff is long gone, their church abandoned. Nature stands still in this place, embalmed by vigorous and ingenious human efforts to maintain a hunter's paradise, but the human presence has dwindled to a small band of environmental biologists, gifted at providing a welcome for the semipalmated plover, but not primarily concerned with the survival of shrimp stew.

Raymond Sokolov, a writer with an interest in the history and preparation of food, is editor of Book Digest.

Louisa Stoney's Brown Oyster Stew with Benne (Sesame) Seed

- 4 slices bacon
- 1 large onion, sliced
- 2 tablespoons flour
- 1½ cups oyster liquor, approximately
- 2 tablespoons sesame seeds, parched in a heavy pan on the stove until browned
- 2 cups shucked oysters
- Cooked rice or hominy

1. Fry the bacon and onion until brown, then remove from the pan with a slotted spoon.
2. Shake the flour into the hot grease and stir vigorously until flour is brown.
3. Remove from heat and gradually add oyster liquor until the mixture is smooth.
4. Pound the sesame seeds, using mortar and pestle.
5. Return flour mixture to heat and stir until slightly thickened. Then add sesame seeds.
6. Lastly, add oysters and poach until the edges curl. Serve over rice or hominy.

Yield: 6 servings

Turtle Soup

- 1 large or 2 small yellow-bellied rice-field turtles (*Pseudemys scripta scripta*), preferably female
- Salt
- Pepper
- 1 teaspoon thyme
- 1 large onion, chopped

1. Butcher turtle as follows: Chop off head. Let stand, head end down, until completely bled. Scald in boiling water for 5 minutes. Then crack or cut through shell with a hatchet, taking care not to damage eggs. Reserve eggs. Cut away the hind quarters and forequarters, the liver, and a strip of white meat adhering to the back of the shell. Peel off outer skin and discard.
2. Bring 4 quarts water to a rolling boil. Add skinned turtle meat and liver, along with seasonings and onion. Reduce heat and simmer for 2 hours or until meat begins to fall off bones.
3. Remove the meat and liver with a slotted spoon. Pull off bones and discard.
4. Chop or grind meat. Chop liver roughly. Return meat and liver to the soup. Correct seasoning. Return to the boil, reduce heat, and add turtle eggs. Continue cooking for 20 minutes.

Yield: 6–8 servings

Connie Bull's Jerusalem Artichoke Relish

- 1 medium cabbage, chopped
- 3 quarts Jerusalem artichokes, well scrubbed and chopped
- 2 large bunches celery, chopped
- 1 quart onions, peeled and chopped
- 6 bell peppers (preferably 3 green and 3 red), seeded, stemmed, and finely chopped
- 1 large cauliflower
- 2 cups salt
- ½ cup flour
- 6 tablespoons dry mustard
- 1 tablespoon allspice
- 3–4 cups sugar, to taste
- 1 tablespoon turmeric
- 1½–2 quarts vinegar

1. Combine cabbage, Jerusalem artichokes, celery, onions, and peppers in a large crock or bowl.
2. Break flowerets off cauliflower and crumble them. Stir together with other vegetables.
3. Dissolve salt in 1 gallon cold water. Pour over vegetables.
4. Cover with towel and let stand for 24 hours.
5. Drain thoroughly.
6. Combine remaining dry ingredients in a bowl, adding just enough vinegar to produce a smooth paste.
7. Bring unused vinegar to a boil. Stir in the paste. Then add vegetables and return to the boil. Reduce heat and simmer for 20 minutes.
8. Spoon into sterilized jars while relish is still hot and seal immediately.

The man behind this hand is Michael Coleman.

The company behind this man is IBM.

There's a story behind both of them.

After the Marines and Vietnam. Coleman earned his MBA and began selling computers for IBM. Promotion followed promotion. and he now teaches our customers how to get the most out of their computers.

His success doesn't surprise us. People with disabilities keep proving that they are as capable as other workers. As reliable. As ambitious. And just as likely to succeed.

At IBM the proof is everywhere. in every part of our business.

The same is true at other companies.

Yet. some people just won't believe that the disabled can do the job. It has to make you wonder who's handicapped.

And who isn't.

NATURAL HISTORY

A Gandharan frieze of gray schist from about the fourth century A.D. The toga worn by the Buddha, center, indicates the Greco-Roman influence on Indian art. The frieze measures about 10 x 15 x 2½ inches. Gift from the Lester Wolfe Collection. Photograph by Arthur Singer, AMNH

The page edges, gilded with a special tarnish-free finish, adding protection as well as beauty to each volume. Magnificent illustrations, some of them in full color. And the bookpaper itself, specially milled to last for many generations.

For these luxurious volumes will be crafted to *retain* their beauty. So that this private library will be a lasting heirloom. To be treasured by you and your family now, and by your children and your children's children in years to come as "the fit inheritance of generations."

Imagine the satisfaction of glancing around your living room and seeing this treasury of great literature—the fifty beautiful volumes which make up The Family Library—the rich leather of their handsome, distinctive spines enriched by 22 karat gold ornamentation.

Imagine the pleasure of anticipation, as you slide one of the volumes from its place, open it at the bound-in ribbon marker, and begin to read. Enjoying the handsomely printed text, the superb, evocative illustrations.

And imagine, too, seeing your family immerse themselves in these challenging and enduring works of literature—and reaping all the rich rewards which that entails.

Return your application
postmarked by September 30, 1981.

The Family Library of the World's Great Books is being offered at this time at the attractively low price of just $19.50 per volume. But it is available at this price *only* to those who subscribe to the complete collection.

The accompanying application assures you of the *guaranteed* price of just $19.50 per volume for the entire Family Library. And you have the right to cancel your subscription at any time upon 30 days' written notice, or return any book, for any reason.

within 30 days. To be accepted, however, your subscription application should be postmarked no later than September 30, 1981.

THE BOARD OF ADVISERS

The Franklin Library gratefully acknowledges the assistance of the very distinguished Board of Advisers in selecting the fifty great books to be included in The Family Library

ISAAC ASIMOV
Noted scientist, professor, critic and writer

PAULINE FREDERICK
Noted correspondent, author and news analyst

DR. BRUNO BETTELHEIM
Distinguished psychologist and author, perhaps best known for his work with children

HELEN HAYES
One of America's greatest dramatic actresses, winner of two Academy Awards

RALPH ELLISON
Distinguished professor and author of the award-winning novel *Invisible Man*

JEAN KERR
Widely popular writer of perceptive and humorous plays and books.

Authors

There is no question about the commitment of **E. D. Starin** to the study of wild primates. She has done fieldwork on chimpanzees in the Gombe Stream National Park in Tanzania, on langur monkeys in the Gir Forest of India and in Sri Lanka, on titi monkeys in Peru, and since 1978, on western red colobus monkeys in the Abuko Nature Reserve in The Gambia. Starin reports that she now dreams about colobus, does chi squares (statistical tests) in her sleep, and would like to remain in The Gambia forever. Her research, concentrated on the socioecology of the colobus, is conducted under the auspices of the Wildlife Conservation Department of The Gambia. Starin is a Ph.D. candidate in anthropology at the City University of New York.

Andrew P. Ingersoll was born in Chicago, grew up in New York City, went to college in New England, and now lives in California. An atmospheric scientist, Ingersoll was an investigator on the *Voyager* missions to Jupiter and is serving in a like capacity on the *Voyager 1* and *Voyager 2* missions to Saturn. Ingersoll was one of a group of scientists on the *Voyager* project team given NASA's Exceptional Scientific Achievement Award for their work. A professor in the Division of Geological and Planetary Sciences at the California Institute of Technology, Ingersoll has a Ph.D. in atmospheric physics. He specializes in planetary temperatures, heat budgets, winds, and climates. Much of his time is devoted to teaching and processing spacecraft data. A devoted family man, he is also a dedicated jogger who tries to put in about five miles a day, even when the exercise has to be done in place.

Interested in the varied historical experiences of Afro-American peoples, **Sally Price** and **Richard Price** have done extensive fieldwork among the Maroons of Suriname, the former Dutch colony in South America. The Maroons are the descendants of slaves who escaped from plantations in the colony and established independent communities in the rain forest. Although the initial focus of their study was not the arts of the Maroons, the Prices were eventually led to investigate the subject because of the Maroons' own concern with aesthetic ideas and products. The Prices are spending a year in the Netherlands doing additional research: Sally Price has a National Science Foundation postdoctoral fellowship to study Maroon folk tales, and Richard Price, on leave from his position as chairman of the Department of Anthropology at The Johns Hopkins University, is completing two books on early Maroon history, supported by a Fulbright Fellowship.

In the summer of 1980, **Elmar R. Reiter** traveled to Beijing (Peking) to attend an international symposium on the role of the Tibet plateau in meteorology. Afterward, he and a group of other scientists crossed the plateau by car and jeep as guests of the government of the People's Republic of China. That trip not only provided him with a new perspective on computer modeling of global weather patterns, but also gave him the opportunity to indulge his hobby of photography. Reiter, who holds a Ph.D. in meteorology and geophysics, is a senior professor in the Department of Atmospheric Science at Colorado State University in Fort Collins. He is the author of "Rapid Rivers of Air," an article on jet streams that appeared in the March 1975 issue of *Natural History.*

The Soligor 80-200mm Expand Your Horizons By Getting Close.

You've got a terrific 35mm SLR camera, but not all of your shots are terrific. Some suffer from too much unwanted scenery, some from tiny people in big frames... shots that didn't work because your creative I.Q. was more than your *lens* could handle.

That's right, lens. But, Soligor has a solution: the affordable, innovative Soligor 80-200mm One-Touch Zoom + Macro lens that lets you and your camera turn blah into beauty.

Zoom in to crop out extraneous details. Bring your subjects up to 4 times closer than a standard lens can. Frame your shots exactly as you want them, and Soligor quality captures them faithfully. Create exciting portraits, instead of just pictures of people; capture a still life or sports action as the kind of picture you bought your camera to get; experiment with amazing close-ups, thanks to macro ability. And it's all so easy with Soligor's single One-Touch control for zoom, focus and macro.

If some of the zip has gone out of your picture taking, zip down to your Soligor dealer and try our 80-200mm on your Canon, Minolta, Pentax, Olympus, Nikon or other fine camera. Or, write for full information.

A Matter of Lights and Death

by John C. Avise and Robert L. Crawford

Every year, large numbers of birds strike transmitting towers. At one Florida tower, the casualties are helping scientists answer questions about avian migration

Supported by a maze of guy wires radiating to ground points up to 800 feet from its base, the WCTV transmitting tower in northern Leon County, Florida, looms above the station. Early one morning in October 1979, a quick survey of the grounds, thirty-four grassy acres as closely mowed as a golf fairway, reveals a score of fluffy clumps—the remains of migrating birds that struck the 1,010-foot tower during the night. The kill appears to be a typical one for an autumn night with overcast skies and northerly winds; a strong cold front might have brought down ten times as many birds. Within an hour, the dead have been collected and recorded: five house wrens, three savannah sparrows, three palm warblers, two common yellowthroats, two long-billed marsh wrens, two yellow-billed cuckoos, one grasshopper sparrow, a wood thrush, a chimney swift, a yellow-throated warbler, a pine warbler, a scarlet tanager, an indigo bunting, and an American coot. The corpses are hurried to the nearby Tall Timbers Research Station, a biological station perhaps best known for its work on fire ecology, where they are bagged, labeled, and placed in a freezer for later study.

In 1955, ornithologist Herbert L. Stoddard, Sr., initiated the study of birds killed at the WCTV tower, and nearly every morning for the past twenty-six years, researchers have collected, cataloged, and preserved the casualties. Stoddard himself, who was a founder and vice-president of Tall Timbers, checked the tower almost daily until 1967, when advancing age finally limited his activities. A succession of workers (most recently, Robert Crawford) have carried on the survey.

The loss of an average of 1,600 birds every year is regrettable, but the WCTV tower kills have been put to good use over the years. They have been made available for a wide range of scientific studies requiring large numbers of specimens. Dozens of publications have resulted, on topics ranging from levels of pesticide residues to genetic relationships, as revealed by protein comparisons, to energetics and fat metabolism. In addition, the collection has provided thousands of museum reference specimens and skeletal preparations. The long-term survey itself provides a wealth of information that could not readily be obtained in any other manner and that can help answer questions about avian migration. Which species are nocturnal migrants? What are the relative abundances, particularly of species that are difficult to separate in the field (such as the *Empidonax* flycatchers)? At what time of year does each species migrate? Is there differential mortality by age or sex? The survey has also contributed to a growing body of knowledge on weather conditions and other factors that influence migration and mortality at fixed structures.

At the WCTV tower, kills occur virtually every night from mid-August to mid-November. Moderate numbers of migrants are often killed under perfectly clear skies, but the toll increases markedly with overcast conditions, especially when the wind is from the north. These conditions are often associated with the passage of a cold front, the boundary between cold and warm air masses. Behind the front, airflow from the north apparently stimulates large flights of migrants. The birds encounter storm systems along the edge of the front and fly lower than they normally do, under the overcast and within tower heights. In addition, birds become disoriented around tower lights when the moisture droplets associated with overcast conditions increase the area illuminated by refraction. For a passing front to produce a large kill, however, a pool of physiologically primed migrants, accumulated in the presence of earlier, southerly winds, is usually necessary.

The slaughter at WCTV is less protracted and more erratic in the spring than in the autumn. Spring migrants also take advantage of wind patterns to aid their flight, moving with the southerly winds blowing out of the Gulf of Mexico. As is true in the fall, clouds associated with approaching weather fronts increase the danger of collision with the tower.

Since only a fraction of the birds that migrate south in the fall survive to re-

Why our survival depends on theirs

So Remorseless a Havoc

Robert McNally

Passionate, moving, and beautifully written, SO REMORSELESS A HAVOC thoroughly details the evolution, physiology, instincts, and migratory patterns of whales and dolphins, the latest theories on the nature of their intelligence, and their significance in man's art, mythology, and literature. Illustrated throughout with photos, diagrams, and line drawings.

"Undoubtedly one of the best books about whales and dolphins and their fate at human hands that I've ever read."—*Farley Mowat*

"Excellent....I couldn't have stopped reading, even if I had wanted to."
—Roger Caras

Available at bookstores, or from NH 981
Little, Brown Distribution Center

turn in April and May, a modest decline in kill numbers in the spring would not be surprising, and tallies for many species collected at the WCTV tower during the years from 1955 to 1980 conform to this general expectation. For example, 353 prairie warblers were killed in the spring compared with 533 killed in the autumn. For many species, the disparity between spring and fall mortality is more striking, and many are grossly overrepresented in fall collections. These include the magnolia warbler (519 of 520 total kills occurred in the fall), blackburnian warbler (374 of 374), chestnut-sided warbler (483 of 483), bay-breasted warbler (466 of 466), ovenbird (811 of 834), brown thrasher (277 of 290), veery (1,018 of 1,114), song sparrow (271 of 274), and white-throated sparrow (512 of 551). A few species, on the other hand, have been found more frequently in spring than in fall (blackpoll warbler, 158 versus 5; green heron, 27 versus 7).

Some of these differences probably reflect seasonal differences in routes and migration behaviors. The autumn route of the blackpoll warbler is largely across the open Atlantic Ocean, where prevailing winds help carry the birds to their winter homes in South America; the spring route is primarily through the Caribbean and peninsular Florida. Many other species, in contrast, pass through north Florida in large numbers in the fall on their way to Central and South America. These species, along with those that are winter residents near the tower, show up in the autumn kills. In the spring, some of the long-distance migrants fly to the west of WCTV. Other species seldom found in the spring kills, such as winter-resident sparrows and some migrants that fly at night in the fall, are thought to migrate northward during daylight hours.

A few species, most notably cedar waxwings and red-winged blackbirds, show peak WCTV tower mortality in the winter months of December, January, and February. The cedar waxwing is a winter wanderer in northern Florida, and red-wings maintained a winter roost near the tower for many years. June is consistently the month of lowest WCTV tower mortality. Over the years about 42,000 tower kills have been counted by the Tall Timbers staff, but only 28 individuals died in June.

Firm conclusions about the relative abundances of migrating species cannot be drawn on the basis of tower kill records alone because many factors affect the results. Early fall migrants such as Louisiana waterthrushes and orchard orioles, for example, are poorly represented at the WCTV tower probably because of the lower frequency and reduced severity of cold fronts in late July and August. A particularly strong front coinciding with a major wave of migrants may also produce potentially misleading statistics. On the night of October 8, 1955, about 2,000 palm warblers died at WCTV. This kill is the largest for a single species ever recorded at WCTV, yet the palm warbler is not otherwise particularly abundant in fall collections.

Information from tower kills is most valuable when compared and evaluated with data from other sources, such as those derived from fieldwork. For example, in the southeastern United States, yellow-billed cuckoos appear much more frequently during spring migration than do black-billed cuckoos. This field observation is supported by the tower kill results: on the average, about twenty yellow-bills are killed per year compared with about two black-bills. Sometimes, however, the data conflict. Tower results argue that the peak of yellow-billed cuckoo spring migration is the middle of May, much later than field observations would predict. This apparent contradiction has been explained. Some yellow-bills do arrive in early April and make themselves known by their distinctive call notes. But many more birds, traveling at night and formerly unnoticed, continue to pass through until late May, well after resident cuckoos have fledged young. The WCTV study has also increased our knowledge about the clay-colored sparrow, a species seldom observed in the field and presumed rare in Florida and nearby states. Six specimens have been recorded at the tower, showing that while the species is rare, it does pass through the area regularly.

Tower kills make possible the accurate determination of the sex and age classes of migrants, sometimes with unexpected results. At WCTV, female ruby-crowned kinglets are significantly more abundant than males. Females of this species are now believed to winter farther south in the United States than males. This behavior could have evolved in response to selection pressures favoring early arrival of males on choice, northerly breeding grounds in spring; it would also lessen intersexual competition during the winter.

Sometimes, the various age classes of a given species occupy largely different wintering grounds. Many autumn birds

Yours to keep... Photographer's Handbook... when you examine *Color*, free, for 10 days.

LIFE library of photography
Each volume features:
handsome, hardbound
9¼" x 9⅜" format;
approximately 200
pages, with index.

Turn ordinary subjects into extraordinary photographs... with Color.

The LIFE Library of Photography Revised Edition, updated to reflect today's revolution in photography...all that's new in automatic cameras, lenses, filters and film techniques...will show you how to take familiar subjects and make exciting photographs.

You'll begin with *Color*...the book that takes you into the more exacting realm of color photography. You'll learn to work with light, the source of color.

You'll learn the rules. And how to break them. From professional photographers like Haas, Eisenstadt and Porter. You'll learn how to take a blurry picture...to capture reflected light for unusual effects...to shoot in the fog, snow or rain...to use light available at different times of day... to diffuse light for beautiful still lifes...to use light to capture emotions in a human face. And much more.

Color is only the first in a series of photographic adventures.

Each book in this handsome collection takes you into a different area of photography... *Photographing Nature, Photographing Children, Travel Photography...* with brilliant photos, demonstration and step-by-step instruction.

Examine *Color,* free, for 10 days! Enter the exciting photographic world of the '80s and beyond.

If card is missing, write to: TIME-LIFE BOOKS, Time & Life Building, Chicago, IL 60611.

TIME LIFE BOOKS

For you...FREE from TIME-LIFE BOOKS... Photographer's Handbook.

68 pages of photographic tips and guidelines. Up-to-date for today's cameras. Take it wherever you and your camera go. It's yours to keep just for examining *Color.*

passing the WCTV tower are trans-Gulf migrants about to embark upon a nonstop flight to Central America. To the east in central peninsular Florida, the WDBO tower, also extensively monitored, is in the flight path of many circum-Gulf migrants: those that will fly directly to South America or island hop through the West Indies. In a comparison of autumn kills at the WCTV and WDBO towers, fourteen species were observed to have significantly different age-class ratios. Out of a total of 2,410 common yellowthroats, for example, adults constituted 29 percent of the kills at WCTV and 64 percent of the kills at WDBO. The comparison was based on data from two different time periods because figures were not available for overlapping years, but our experience has been that mortality patterns do not vary considerably from year to year. The evidence suggests, then, that the two towers may well be sampling different age cohorts of migrants on their way to separate wintering areas.

Whatever the sex or age, almost all birds killed at towers are nocturnal migrants since diurnal migrants easily avoid collision with communication towers. The food habits of a species appear to be important in determining the time of migration flights. For songbirds that forage on the ground or in wooded areas and rely on daylight to find prey, migration flights occur primarily at night during the normal sleep period. Thus these birds avoid what would otherwise be at least a 36-hour fast (from the night preceding a daytime flight through the following night). Species that normally feed on the wing during the day tend to be diurnal migrants, simply feeding as they travel.

Most sparrows, warblers, vireos, kinglets, cuckoos, wrens, thrushes (except the eastern bluebird), and mimic thrushes are nocturnal migrants, and all of these groups are well represented in the WCTV morgue. Waterfowl and shorebirds, some of which migrate at night, are rare at WCTV, but this may be partly because the tower is not located on a major flyway. Hawks, swifts, and swallows—familiar diurnal migrants—are represented by a total of only fifty-four corpses in twenty-six years at WCTV, and some of these deaths may have occurred during crepuscular flights. Several of the findings have been a surprise. Eastern kingbirds and American goldfinches are common migrants at Tall Timbers but are rarely found among the tower kills. Perhaps they migrate primarily during the day. And although cardinals in the Southeast are generally thought to be nonmigratory, the species is apparently a common night migrant at Tall Timbers, judging by the fifty-four specimens recovered between 1955 and 1980.

The WCTV tower returns suggest that species occasionally migrate in large flights. On May 2, 1964, 104 gray-cheeked thrushes were picked up at the base of the tower. This represented well over half the total gray-cheek kills recorded in the first eleven years of the study. On October 5, 1957, 126 gray catbirds were found at the tower. The same night brought down 54 summer tanagers, 163 American redstarts, 194 hooded warblers, and about 50 northern waterthrushes. Seventy-six prairie warblers were tallied on August 20, 1957, and the record kill of about 2,000 palm warblers in 1955 has already been mentioned.

Red-eyed vireos, by far the most abundant of the kills at WCTV and perhaps the most common species in all tower kills, account for about 17 percent of total deaths in the Tall Timbers study. Average mortality at this tower alone is about 286 birds per year, suggesting that the total slaughter of red-eyed vireos at all towers must be enormous. In contrast, a number of species (including the double-crested cormorant, horned grebe, great horned owl, and white ibis) have been recorded at the tower only once, but undoubtedly the most unusual casualty was a black-capped petrel found on September 11, 1964. This normally oceanic bird had apparently flown inland with the eye of a hurricane, only to succumb to a steel pillar.

Despite the huge number of specimens of all sorts collected in this 26-year study, only two birds carried bands: a brown thrasher, picked up on October 19, 1966, and banded on May 23, 1964, at New Brunswick, New Jersey; and a veery, picked up on September 25, 1965, and banded on September 1, 1965, near Chestertown, Maryland.

The largest single night kill ever recorded at Tall Timbers occurred just one week after the survey was begun. On the morning of October 9, 1955, Stoddard arrived at the base of the first WCTV tower, a 673-foot-tall structure, to find the grounds littered with an estimated 4,000 to 7,000 dead and dying birds; only 1,988 specimens of 62 species were identified before the rest were lost to decomposition and scavengers. In 1960, the original tower was replaced by the present 1,010-footer, with twenty-one guy wires, three sets of blinking red lights, and twelve small nonblinking red lights. The taller tower has not increased the recorded number of tower kills, and since 1967, recoveries have actually gone down sharply. The lower tallies, however, are perhaps primarily due to a reduced program of scavenger control.

One of the most dramatic findings of the WCTV study concerns the profound influence of predators and scavengers at the tower. If left unchecked, predators harvest large numbers of the birds killed and crippled during the night and early morning. The problem can hardly be overstated. On nights when there are massive kills, predators become supersaturated with food and do not severely influence census counts of tower kills, but on more usual migration nights, when perhaps five to one hundred birds are knocked down, scavengers may cause the disappearance of 50 to 100 percent of the kills before a tally can be made. The Tall Timbers staff has conducted many studies to document predator influence on counts. One night, for example, sixty experimentally marked corpses were scattered about the tower; by early morning all had disappeared. Many specimens vanish without a trace, but others leave "feather puddles" as evidence of the deed. The perpetrator may also leave clues to its identity—pellets, scats, feathers, tracks, scents, or partial prey remains.

We believe that entire predator–scavenger communities may develop around productive towers. The WCTV ornithologists have had to contend with a wide variety of competitors, including feral cats and dogs, escaped hogs, opossums, raccoons, bobcats, foxes, and skunks. Two of the more unusual scavengers observed at the tower were a toad found trying to swallow a dead bird and a cotton rat surprised while chewing on a ruby-crowned kinglet. Loggerhead shrikes frequently add WCTV birds to their larders, impaling them on barbed-wire fences at the tower site, and flocks of crows search the grounds each morning. Earwigs, yellow-jacket wasps, and a species of gray garden slug, *Deroceras laeve,* often feed on the dead birds. The eight species of ants that eat the tower birds, reducing them to a pile of feathers and bones in just a few hours, can be especially annoying when museum specimens are desired because an ant-infested bird may at first sight look intact and un-

The Onkyo TA-2050.
It will elate you, enfold you, exhilarate and enrich you.

The Onkyo TA-2050 is the most exciting stereo cassette tape deck in its price range. Nothing else provides the brilliant purity of its sound, or gives you so much control over the quality of your recording and playback.

The Onkyo TA-2050 provides all the features you'd want in a precision tape deck . . . and more. Onkyo's exclusive Accu-Bias system lets you "fine tune" your recording bias to customize sound. Peak reading meters (with decay) let you set more precise recording levels. Fade out/fade in controls, record/mute controls, and soft-touch switches with IC-logic . . . let you edit more professionally. Memory-stop/memory-play . . . remote control and timer/mode capability . . . 2-motor direct drive precision . . . and full metal tape compatibility . . . are just a few of the other important features the TA-2050 offers.

The Onkyo TA-2050 is a tape deck you can grow with. Hear it now at your Onkyo dealer.

Onkyo USA Corporation, 42-07 20th Ave., Long Island City, N.Y. 11105. (212) 728-4639 ONKYO

touched. The most troublesome scavengers at WCTV, however, are great horned owls. In an early report, Stoddard wrote: "As far as Horned Owls are concerned we are now reconciled to the fact that we will have to fight them every Spring and Fall migration for our share of the frequent kills. As we remove one owl, another soon appears and rather quickly learns when and where to look for dead birds."

The scavenger problem at WCTV became so severe that Stoddard and Robert A. Norris, who joined the project in 1962, reluctantly instigated various means of predator control. Owls, the primary target, were trapped and transplanted to other areas, and a few particularly wary offenders had to be killed. Some of the dead owls were prepared as scientific skins; the plumages of others were presented to Indian tribes of the Southwest for ceremonial use. One horned owl, trapped and banded at WCTV on July 15, 1974, was released in a national forest more than twenty miles south of the tower. It was retrapped at the same spot on the tower grounds on October 5, 1977, an unusual instance of homing by this species. Predator control was largely discontinued in 1966, with the result that total recoveries of WCTV tower kills have dropped dramatically. At man-made structures elsewhere, other scavengers, such as gulls, coyotes, and rats, probably cause consistent gross underestimates of total bird mortality. In Tennessee, even box turtles have been seen eating tower-killed birds.

In the early days, with or without competition from scavengers, the WCTV survey was hampered because the tower grounds effectively hid most of the kills. Small birds are extremely difficult to find in anything but the shortest grass, and most of the grounds were covered by thick weeds, with the remainder planted in corn, sweet potatoes, and other row crops. After the first year, however, twenty acres under the tower were disked and sown with grass; later, the area was expanded to thirty-four acres. Now maintained for the express purpose of facilitating kill recovery, this grassy area requires repeated use of a seven-foot, tractor-drawn mower for ten months of the year. One reason the serious threat that towers pose to migrants generally goes unrecognized is that most carcasses are not likely to be discovered unless the area is fastidiously maintained.

Probably the single worst avian mortality reported at a communication tower occurred during the nights of September 18 and 19, 1963, when an estimated 30,000 birds were killed at a TV tower in Eau Claire, Wisconsin. In 1975, there were 7,800 radio and 950 TV stations in the United States, and their cumulative effect is surely far from trivial. One estimate is that in the United States alone, more than one million birds die annually in accidental collisions with towers. Transmitting towers, however, are not the only man-made obstacles to avian migration. Lighthouses, chimneys, cooling towers, buildings, telephone and power lines, and public monuments contribute to the toll. A recent compilation found more than 1,040 references relating to mass avian mortality at such structures, and these may represent only a minute fraction of actual incidents. The Washington Monument in the nation's capital was the site of several reported kills in the late 1930s. For many years the Empire State Building in downtown New York used to kill large numbers of birds, attracted by a powerful fixed beam on top of the building and later by the intense glow of floodlights. Efforts are now made to have the floodlights turned off during overcast migration periods. On the night of September 27, 1962, about 6,000 birds met their death at the ceilometer of an Air Force base in San Angelo, Texas. Another 2,000 birds died on September 30, 1973, at a 1,000-foot smokestack in Chesire, Ohio. The Toronto-Dominion Center in Canada and a downtown office complex in Atlanta, Georgia, report frequent kills. The list goes on. Incidents of birds killed by striking windows or overhead wires have been less frequently reported, but investigators have estimated that these structures may cause even greater mortality.

The reasons so many migrants collide with transmitting towers and other tall structures remain a partial mystery. One theory is that transmitting towers, acting like giant rods, alter the electric field that surrounds them and somehow affect birds' navigational ability. This hypothesis, however, cannot be applied to lighthouses, ceilometers, or other obstacles that also act as death traps, and a more likely candidate for the most important factor in migration disasters appears to be the lighting condition. Bright lights are alluring to birds, particularly on cloudy, drizzly nights. In 1885, ornithologist William Brewster described the effect at the Point Lepreau Lighthouse on the Bay of Fundy, New Brunswick.

> As soon as the sky became overcast small birds began to come about the light [and] with the advent of fog they multiplied tenfold in the course of a few minutes. For the next hour from 30–100 were constantly in sight, and from one to eight to ten dashing at the lantern.... About 20% struck so forcibly as to injure themselves beyond hope of recovery, often, however, fluttering off the platform and down to the ground beneath.... At the height of the melee the scene was interesting and impressive beyond almost anything that I ever witnessed. Above, the inky black sky; on all sides, dense wreaths of fog scudding swiftly past and completely enveloping the sea which moaned dismally at the base of the cliffs below; about the top of the tower, a belt of light projected some 30 yards into the mist by the powerful reflectors; and in this belt swarms of birds, circling, floating, soaring, now advancing, next retreating, but never quite able, as it seemed, to throw off the spell of the fatal lantern.

An increased understanding of the conditions favoring avian mortality has led to some improvements in lighting design. In Great Britain, kills at one lighthouse have been drastically reduced by replacing revolving white beacons with flashing bluish lights. The substitution of rotating- for fixed-beam ceilometers in the early 1960s apparently all but eliminated kills at these installations. Few hard data are available as to whether alterations in lighting conditions at communication towers successfully reduce kills. The lights on towers have historically been red and white, suggesting that experiments with different wavelengths, intensities, and flash rates of lights may be fruitful. Any changes in lighting design cannot, of course, compromise the primary function of the lights—safety in human air navigation.

If there is a happy note on which to close a morbid topic, it must surely be the productive use made by scientists of the WCTV tower kills. In an age all too often characterized by short-term ecological studies, the WCTV study is unusual for its longevity. In the years ahead, the unfortunate birds that collide with the tower and wind up in the Tall Timbers freezer will continue to provide valuable information about avian migration.

John C. Avise is associate professor of genetics in the Department of Molecular and Population Genetics at the University of Georgia. Coauthor Robert L. Crawford is a curator and ornithologist at Tall Timbers Research Station in Tallahassee, Florida.

Quaggas, Coiled Oysters, and Flimsy Facts

False views are fun to disprove, but a false fact may become a long-lived burden for science

by Stephen Jay Gould

As Darwin cataloged cases of striped horses and asses to illustrate a common ancestry with zebras, he inevitably encountered one of the most famous animals of nineteenth-century natural history—the Earl of Morton's mare. Darwin wrote in the *Origin of Species:* "In Lord Moreton's [*sic*] famous hybrid from a chestnut mare and male quagga, the hybrid, and even the pure offspring subsequently produced from the mare by a black Arabian sire, were much more plainly barred across the legs than is even the pure quagga."

The quagga, a zebra with stripes restricted to its neck and forequarters, is now extinct. It was not thriving in the early nineteenth century either, when the good Earl hoped to save the species by domesticating it. He was able to procure a male for his noble experiment but could never obtain a female. So he bred his male quagga with "a young chestnut mare of seven-eighths Arabian blood," and obtained a hybrid with "very decided indications of her mixed origin." Nothing surprising so far.

But the disappointed Lord Morton, unable to find more quaggas, sold his Arabian mare to Sir Gore Ouseley, who proceeded to breed her with "a very fine black Arabian horse." When Lord Morton visited his friend and viewed the two offspring of pedigreed Arabian parents, he was astonished to note in them what he took to be a "striking resemblance to the quagga." Somehow, the quagga father had influenced subsequent offspring sired by other males years after his permanent departure from the life of Lord Morton's mare. How could such an influence be maintained long after physical contact had ceased?

Lord Morton's mare represents the most celebrated, but by no means the only, case of a phenomenon that German biologist August Weismann later named "telegony," from Greek roots meaning "offspring at a distance," or the idea that sires could influence subsequent progeny not fathered by them. Since the supposed phenomenon turned out to be an illusion, telegony now reposes as one more forgotten item on history's ash heap, and neither Lord Morton nor his mare retain any notoriety today.

But historian of science Richard W. Burkhardt, Jr., who recently wrote an excellent article on the history of telegony in general and Lord Morton's mare in particular (*Studies in History of Biology,* vol. 3, 1979, pp. 1–21), has demonstrated that telegony was once a major subject for research and "inspired the most extensive work in experimental animal breeding conducted in Britain between Darwin's death in 1882 and the rediscovery of Mendel's law in 1900." Darwin himself was a major supporter of telegony.

If the supposed causes of telegony are a bit mysterious, Darwin's reasons for espousing the idea may seem equally difficult to fathom. After all, he first discussed the progeny of Lord Morton's mare in a different context that implied an explanation opposed to telegony. As I wrote in my last two columns (this, I promise, is the last word for a while on zebra stripes), Darwin had cataloged all cases he could find of asses and true horses with stripes. And he had uncovered a bounty. He used his striped horses as an effective argument for evolution: If God had created true horses, asses, and zebras as separate forms, why should species that normally do not have stripes develop them quite frequently? Does not this latent tendency for striping in all horses (permanently actualized only in zebras) indicate common descent? In this context, why did Darwin later implicate the previous quagga sire in the striping of subsequent offspring from Lord Morton's mare? In this first discussion,

A quagga

from the *Origin of Species,* Darwin only wanted to prove that true horses and asses can develop stripes *without* any zebra influence. As we shall see, this original explanation was apparently correct.

Burkhardt argues that Darwin changed his mind and supported telegony because it fit so well with the (ironically) "non-Darwinian" theory of heredity that he developed in 1868. Under this "provisional hypothesis of pangenesis" (as Darwin called it), all cells of the body produce tiny particles, called gemmules, that course throughout the body, gather in the sex cells, and eventually transmit the characters of parents to offspring. Since gemmules might be altered if the cells producing them are changed by the influence of environment or the activity of animals themselves, acquired characters can be inherited and evolution has an important Lamarckian aspect.

Telegony meshed well with pangenesis because gemmules included with the quagga's sperm would have remained in the body of Lord Morton's mare and extended their influence to her subsequent offspring. (Darwin even once speculated that gemmules passed in sperm might explain why some women grow to resemble their husbands. As to why so many people resemble their dogs, Darwin maintained a discreet silence.)

Telegony finally fell when a new theory of heredity rose to favor and excluded it. August Weismann, who championed the strict Darwinism of natural selection against all forms of Lamarckian inheritance (including Darwin's own pangenesis), argued for what he called "the continuity of germ plasm." He held that reproductive cells are completely isolated from the rest of the body and cannot be influenced by whatever forces mold and alter other organs and tissues. Acquired characters cannot affect the next generation because they cannot penetrate the "cas-

THE TROPICS IN DANGER

The JAGUAR is one of the many inhabitants of tropical rain forests—in fact, more than half of the world's plants and animals live in these forests.

If present trends continue 500,000 or more species will be extinct within the next 20 years. Most of these losses will occur in tropical rain forests.

Concerned people everywhere must band together to protect these vital resources.

RARE is a non-profit, volunteer based organization devoted to the protection of endangered plants and animals. RARE is doing all it can but WE NEED YOUR HELP TO PROTECT THE JAGUAR. Your contribution will help save this beautiful cat.

The "Jaguar" painting by Bonnie L. Marris is available in three 18x24 full color editions.

(1) Jaguar conservation poster with a contribution of $15.00.
(2) Signed and numbered print from the limited edition of 500, on 100% cotton stock, with a remittance of $125.00.
(3) Special remarqued edition of 250 prints with a donation of $175.00.

Please specify your choice and make checks payable to RARE, Inc.

ket" that holds reproductive cells and transmits itself in toto from generation to generation. (The fertilized egg, of course, is formed by the union of two reproductive cells. As it starts to divide, however, the nonreproductive cells form, eventually develop into the organism's body, and become rigidly segregated from the continuous lineage of germ cells. Telegony makes no sense because, even if they existed, male gemmules in a female's body could not get to the germ cells—unless, of course, they managed to reach the ovaries themselves and modify the immature ova.)

Telegony kicked about in scientific literature for seventy years, from Morton's note to the Royal Society in 1820 until Weismann's challenge. When Weismann proposed the continuity of germ plasm, telegony became a threatening anomaly demanding affirmation or rejection. Many tests were made, and telegony failed them miserably. In particular, J.C. Ewart, Regius Professor of Natural History at Edinburgh, tried to repeat Morton's own experiment. Since quaggas had joined *Eohippus* in the realm of departed horses, Ewart mated twenty mares of different races and breeds with a male Burchell's zebra. The first hybrid, born in 1896, had stripes as expected. Ewart then mated the mare with a second sire, an Arab stallion. Their offspring also had stripes, albeit faint, and telegony seemed vindicated. But Ewart knew that he needed controls and therefore bred the same Arab stallion to other mares that "had never so much as seen a zebra." The offspring of these matings were as richly striped as the foal from the mare that had previously mated with a zebra. Darwin had been right the first time. Stripes do not arise from a mysterious previous zebra influence; they represent a potential pathway of development for all horses.

I have not recounted this tale of telegony for its own sake, since antiquarian musings only excite professionals and trivia buffs. Rather, as Burkhardt emphasizes, the story embodies a larger, troubling, and important issue about the nature of fact in science. Telegony, so far as we can tell, was wrong; yet it remained in the literature as a pristine fact, largely unchallenged, for seventy years. In a reversal of the stereotyped scenario, where a single sturdy fact arises to destroy an entire edifice of theory, the "fact" of telegony came first, became entrenched, and was only seriously challenged when a theory—Weis-

mann's continuity of germ plasm—rendered it anomalous. Burkhardt writes that in the usual model "a long-accepted theory is toppled by a newly discovered, apparently anomalous fact. In the case of telegony, in contrast, a long-accepted 'fact' was discredited when confronted with a new, apparently contradictory theory."

In part, Burkhardt suggests, telegony gathered favor because it fit well with a variety of nineteenth-century assumptions, ranging from the "natural" dominance of males over females to support for separation of races by the argument that sexual contact with a lower race might extend its baleful influence far beyond the immediate consequences of the act itself. In part, telegony simply wasn't controversial enough and nobody bothered to test Lord Morton's improbable assertion. When tested, telegony fell, and to this extent the usual model of science as objective experiment was vindicated. But another aspect of the conventional view did not apply: fact did not act as the cleansing broom for outmoded theory. Rather, a false "fact" endured for an uncomfortably long time until theory demanded its test. What does this story tell us about the relation of fact and theory in science and about the role of single, isolated facts in the first place? I will return to these generalities, but first, another and similar tale.

In 1922, British paleontologist A.E. Trueman published the most famous paper of our century on a supposedly unbroken lineage of evolving fossils. He argued that flat oysters had slowly evolved into coiled oysters of the genus *Gryphaea*. Although coiling was originally advantageous in raising the oysters above an increasingly muddy sea floor, the trend, once started, could not be halted. *Gryphaea* built one coiled valve and one flat valve lying like a cap atop its coiling partner. Eventually, the coil grew up and over the cap, finally pressing hard upon it. Unable to open its shell, *Gryphaea* perished, imprisoned in its own embrace.

When Trueman published his paper, most paleontologists were not Darwinians. The theory of orthogenesis, or "straight line" evolution forcing organisms along predetermined paths, was still popular. An inexorable trend that natural selection could not stop and that led to the demise of a lineage was an expected phenomenon. Thus, Trueman's story was not challenged by paleontologists, and like the zebra's impact on Lord Morton's mare, overcoiled

Do you have room in your home for three wise men? They are Plato, Aristotle, and Marcus Aurelius...three of the wisest, wittiest, most stimulating minds that ever lived.

They still live...in the Five Great Dialogues of Plato, the Meditations of Marcus Aurelius, and Aristotle's On Man in the Universe.

All three books (regularly $25.47) can be yours for only $1.00 as your introduction to the Classics Club.

The Classics Club is quite unlike any other book club.

The Club doesn't offer best sellers that come and go. Instead, it offers its members a chance to stay young through great books that will never grow old. These books include Utopia by Thomas More; the works of Shakespeare; Benjamin Franklin's Autobiography; Omar Khayyam's Rubaiyat; Walden by Thoreau; and other fresh, spontaneous, even outspoken works that stretch your mind and sweep away the mental cobwebs that hold back most men.

You never have to buy any of these books. (To force you to buy a classic would be barbaric.) As a member, take only those books you really want to own. And, at any time, you may cancel your membership, without penalty or hurt feelings.

The selections themselves are remarkable values. They're carefully printed on expensive paper stock. They're hard-bound in matched wheat-colored buckram, worked and stamped in the colors of crimson, black and gold. And through direct-to-the-public distribution, we are able to offer to our members these deluxe editions for only $8.49 each, plus shipping.

Interested? We'll send you the first three selections, Plato, Aristotle and Marcus Aurelius – all three for only $1.00 plus shipping.

We know what charmers these three wise men are. We're betting that you'll be so taken by them that you'll want to stay in the Club and meet some of their friends, including the greatest story tellers, philosophers, poets, and historians the world has ever known.

Don't send any money now. We'll bill you later. Just fill in the coupon below, now, while you're thinking about it and while the invitation still stands.

Mail coupon to The Classics Club, Roslyn, New York 11576.

LET THESE 3 WISE MEN INTO YOUR HOME.

LATER, YOU MIGHT LIKE TO INVITE THEIR FRIENDS.

THE CLASSICS CLUB ROSLYN, N.Y. 11576

Please enroll me as a member and send me at once Plato, Aristotle and Marcus Aurelius. I enclose *no money now*. After a week's examination, I will either keep my books and pay $1 (plus shipping) or return them. As a new member, I will get a complete list of titles from which to select the books I want. For each volume I choose, I pay only $8.49 (plus shipping). I may return any book, for full credit within 21 days and I may cancel my membership at any time. Note: Members accepted in U.S.A. and Canada only. Offer slightly different in Canada.

THE OFFICIAL ROYAL WEDDING CROWN COIN

Electroplated in
PURE 24-KARAT GOLD

Actual Size

Exclusive Offer Only $5.

On July 29th, the wedding of the future King and Queen of England took place at London's famous St. Paul's Cathedral. To honor this historic event, The Royal Mint of England is minting a special legal tender Crown Coin. The Crown coin is the largest coin in England — heavier and larger than a United States Silver Dollar. This is the first time in England's long history that a Royal Wedding Crown coin has ever been issued. Crown coins are minted by The Royal Mint only for rare occasions and as such are sought after and hoarded by collectors in England for future generations. Truly a collector's coin of untold historic value, it will be cherished and valued for years to come.

The face of the coin bears the likeness of HRH Prince of Wales and Lady Diana Spencer, The reverse, the famous portrait of Her Majesty, Queen Elizabeth by Arnold Machin, which graces every coin currently circulating in England.

EXCLUSIVE OPPORTUNITY

You have an exclusive opportunity to acquire a limited number of these coins as a direct result of the special arrangements The Columbia Mint has made to make them available to collectors in the United States. The Royal Wedding Crown Coin, embellished in pure 24 Karat Gold—The Metal of Royalty—mounted in a protective serially numbered display wallet along with an historical account of the wedding, can be yours for just $5 each plus 50¢ postage and handling, but supplies are limited. Due to the limited supply, there will be a strict limit of (5) Crowns per order.

For faster service, credit card charge orders may call FREE 24 hours a day
Minimum order $10
800-228-5000

LIMITED AVAILABILITY — ACT NOW

The Royal Wedding Crown will only be minted this one time and never again. Therefore, you should not delay in placing your order. Only by doing so can you be assured of the right to own this historic and majestic beautifully electroplated Crown in pure 24-Karat Gold. Send your order today to The Columbia Mint, 905 Sixteenth Street N.W., Washington, D.C. 20006. But do it now as you may never have this opportunity again.

Better Than Jogging

NordicTrack

Jarless Total Body Cardiovascular Exerciser Duplicates X-C Skiing for the Best Motion in Fitness

This revolutionary new exerciser duplicates the smooth, rhythmic, total body motion of X-C skiing for the most effective cardiovascular exercise obtainable. Uniformly exercises more muscles than any other exercise device. Makes high heart rates easy to obtain and keeps more muscles in tone. Also highly effective for weight reduction.

Completely jarless natural motion does not cause joint and back problems as in jogging or running. Arm and leg resistances are separately adjustable for maximum effectiveness. The NordicTrack uses no motors and folds compactly for convenience. Used in homes, businesses, and institutions. Our customers include Xerox Corporation, US Army, Penn State U and the YMCA.

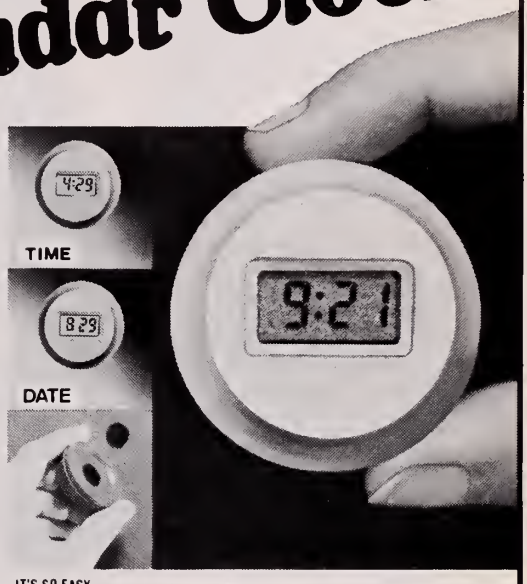
Gryphaea became established as a fact.

In the late 1930s, after a gestation of nearly one hundred years from Darwin's great insight and eighty years from its publication, natural selection finally triumphed as the accepted theory of evolutionary change, and *Gryphaea* became an anomaly. How could a lineage *actively* evolve itself to extinction if all evolutionary change is directed by natural selection and can, therefore, only occur in directions that adapt organisms to local environments? (Extinction based upon an inability to change rapidly enough in the face of environmental perturbation is another matter and perfectly orthodox in a Darwinian world.)

Darwinians reacted to *Gryphaea* in a variety of ways, but all were deeply troubled. Some, like J.B.S. Haldane, simply admitted puzzlement: "The exaggerated coiling of *Gryphaea* cannot at present be explained with any strong degree of likelihood." Others, like G.G. Simpson, tried to steer around the problem with faintly plausible, but evidently ad hoc suggestions: since overcoiling only affected the oldest, and probably postreproductive, individuals, it may even have benefited the population by clearing out the old codgers and making space for the young and vigorous. Yet, through all these efforts in salvaging natural selection, no one asked the more basic question, Is it even true in the first place? Overcoiling in *Gryphaea* had become a fact.

But it is not true; overcoiling in *Gryphaea* is as chimerical as the supposed influence of Lord Morton's quagga upon the subsequent progeny of his mare. In 1959, Anthony Hallam, now a good friend and professor of geology at Birmingham, but then a brash graduate student, wrote an iconoclastic paper with two controversial claims: first, that *Gryphaea* had not evolved from flat oysters at all, but had migrated into southern England from elsewhere; and second, that *Gryphaea* arrived in England as coiled as it would ever be—and that no trend to increased coiling within *Gryphaea* could be demonstrated at all. Hallam's conclusion scandalized many senior scientists who had known Trueman. H.H. Swinnerton, dean of British paleontology, wrote back in anger, accusing Hallam of both "sin" and "monstrous error," an odd pair of accusations for a scientific paper.

Twenty years later the dust has settled, and I do not think that anyone would now doubt Hallam's debunking. For Hallam's first claim—that *Gry-*



phaea did not evolve from flat oysters—H.B. Stenzel's impressive monograph (*Treatise on Invertebrate Paleontology,* Geological Society of America and University of Kansas Press, part N, vol. 3, 1971) has proved that the lineages of flat oysters (genus *Ostrea*) and coiled oysters (genus *Gryphaea*) have been separate from their first appearance, that *Gryphaea* is a bit older than *Ostrea,* and that coiled ancestors for Trueman's *Gryphaea* were living in Greenland before *Ostrea* ever appeared in England.

For his second claim—that *Gryphaea* did not increase in coiling during its evolution—I have reexamined all the published data and concluded that while *Gryphaea* did increase in body size, its degree of adult coiling remained constant. Ironically, this means that later *Gryphaea* were actually more loosely coiled than earlier specimens of the same body size, for coiling increases with growth, and if a larger adult descendant will reach the same intensity of coiling as its smaller adult ancestor, then the descendant's shell must be more loosely coiled when it is still a juvenile of the same size as its ancestral adult. (I have reprinted all major papers from the great *Gryphaea* debate in a volume entitled: *The Evolution of Gryphaea,* Arno Press, 1980.)

If Trueman's edifice toppled so easily, why was his "fact" accepted so readily in the first place? One might suspect that the overcoiling of *Gryphaea* had received lengthy and complex documentation, however unreliable it proved to be, and that Trueman simply snowed potential critics. Not at all. The original evidence was flimsy almost beyond belief, and this, to me, is the most curious aspect of the entire tale. In his 1922 paper, Trueman showed how most large adult *Gryphaea avoid* calamitous overcoiling by decreasing the tightness of their spiral late in growth.

Trueman's claim for overcoiling was based on a single specimen, the "type" (or name-bearing) specimen of the species *Gryphaea incurva.* I examined this specimen at the British Museum in 1971. At first glance, the coiled valve does seem to press hard upon the flat valve. But the specimen was recovered from very fine-grained muds of the same color as the shell itself. A bit of probing revealed—and X-ray photographs later confirmed—that the supposed "lock" upon the flat valve had not been formed by the coiled valve itself, but by mud that wedged its way

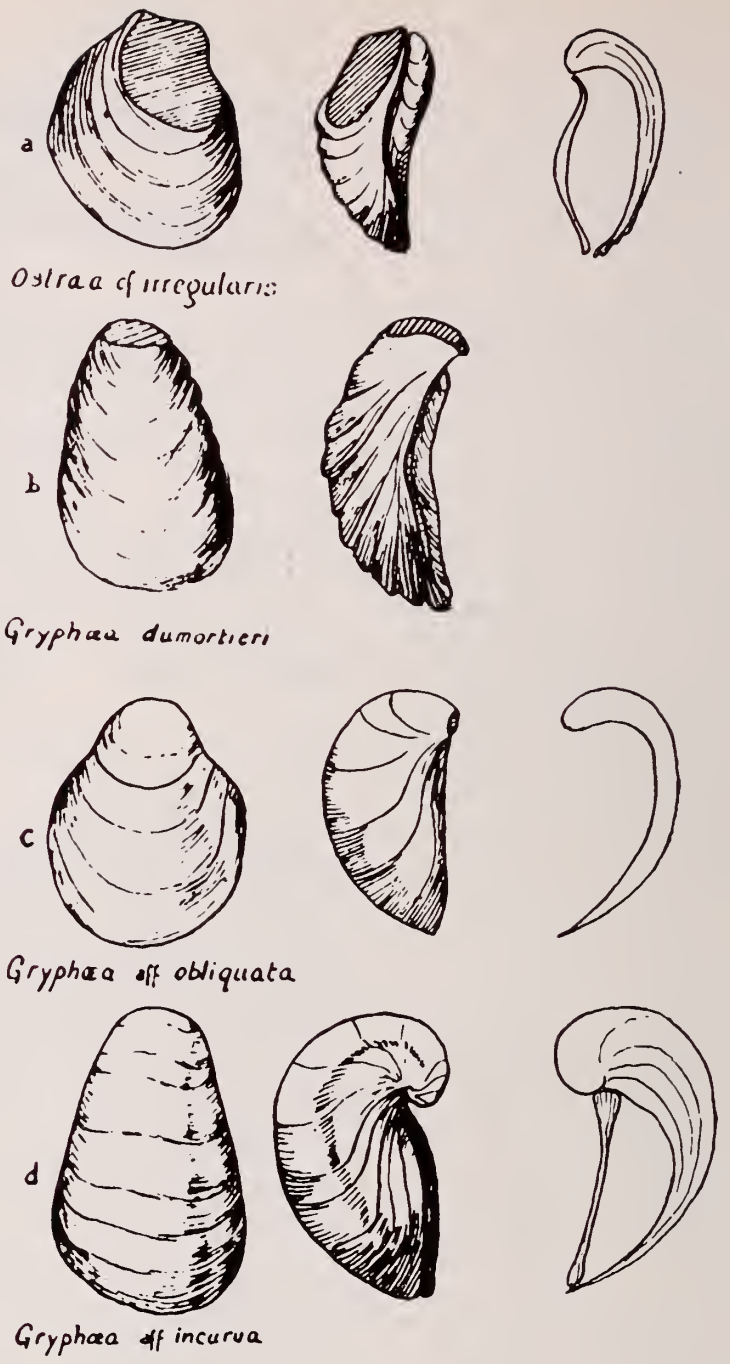
DR. THOR HEYERDAHL in search of man's beginnings...



"Surpasses *The Ra Expeditions* or *Kon-Tiki*."—*Publishers Weekly*. For five months famed researcher, sailor and explorer Thor Heyerdahl traced the trade routes that flourished a thousand years before the birth of Christ, aboard a reed ship built after a pattern more than three millennia old. "Rewarding...an eye-witness passage into the dim past."
—*Kirkus Reviews*

THE TIGRIS EXPEDITION

More than 100 color photos, map, $17.95

DOUBLEDAY

Paleontologist A. E. Trueman illustrated the supposedly inexorable evolution of oysters of the genus Gryphaea *from flat* (a) *to coiled* (d) *in this drawing from a 1922 issue of* Geology Magazine.

into the space between flat and coiled valve, the space that allowed the shell to open, after the animal's death.

If telegony and overcoiling are false "facts," why did each command prestige and inspire no attempt at refutation for so long? I believe, first of all, that the reputation of false facts is bolstered by the naïve belief that facts are bits of unsullied information extracted from nature by an objective process of pure observation or by scientific inference. Facts arise in contexts of expectation, and both the eye and the mind are noto-

FREE Fall Catalog

Fully illustrated. Features quality apparel and footwear for men, women and children; camping, hunting, hiking and winter sports equipment. For 69 years L. L. Bean has offered practical and functional merchandise at reasonable prices. Our clothing and footwear is rugged enough to withstand active outdoor use, yet attractively styled and comfortable for casual wear. Many items are of our own manufacture. All are guaranteed to be 100% satisfactory.

riously fallible instruments. (Anyone who thinks that claims for direct observation possess some special, irrefutable status should read Elizabeth Loftis's chilling book on eyewitness testimony.) Paleontologists, accepting the reality of orthogenesis, were primed to believe in *Gryphaea*'s overcoiling; telegony seemed reasonable until Weismann challenged it seventy years later. Secondly, facts achieve an almost immortal status once they pass from primary documentation into secondary sources, particularly textbooks. No medium is so conservative as the textbook; errors are copied from generation to generation and seem to gain support by sheer repetition. No one goes back to discover the fragility of original arguments.

I am not trying to convey the message that all knowledge is relative and that facts can never achieve universal approbation—quite the reverse. Rather, we have to distinguish which kinds of factual claims can achieve acceptance and which must remain in limbo. The most troublesome facts are single cases—the offspring of Lord Morton's mare, the overcoiling of one *Gryphaea*. We must, as William Bateson advised, "treasure our exceptions." But we must also be aware that single cases are fragile, and that sturdy facts are pervasive patterns in nature, not individual peculiarities. Most "classic stories" in science are wrong.

The need to distinguish sturdy fact (pervasive pattern) from shaky factual claim (single cases with dubious documentation) has never been more evident to me than in the current debate between evolutionists and those latterday antediluvians who call themselves, in the nonsense phrase of the decade, "scientific creationists." The fact of evolution is as sturdy as any claim in science (which does not mean that it is absolutely certain, because nothing is, aside from ignorant dogmatics). Its sturdiness resides in a pervasive pattern detected by several disciplines—for example, the age of the earth and life as affirmed by astronomy and geology, the pattern of imperfections in organisms that record a history of physical descent (the primary contribution of biology and the theme of so many of these columns).

Against this pattern, creationists employ the destructive, shotgun approach—presenting no testable alternative but firing a volley of rhetorical criticism in the form of unconnected, shaky factual claims—a potpourri (literally, a rotten pot, in this case) of nonsense that beguiles many people because it masquerades in the guise of fact and trades upon the false prestige of supposedly pure observation.

The nihilistic strategy goes something like this, and it forms effective, if ugly, rhetoric: this African carbon-14 date is way off, so radioactive decay can't affirm the earth's antiquity; these rocks from Colorado are younger than rocks piled on top of them, so geological succession does not record time. The individual claims are easy enough to refute with a bit of research. Creationists themselves have been forced to retreat from the more embarrassing items. Noted creationist Henry Morris, for example, has often cited the supposed footprints of dinosaurs and humans together in rocks of the Paluxy River of Texas. But creationist Leonard Brand attributes some of the "human" prints to erosion and others to a three-toed dinosaur. He also adds: "We do know that there was a fellow during the Depression who carved tracks."

Yet each time we explode one creationist "fact," two more are invented to take its place. Hercules finally killed the Lernaean Hydra, a beast with similar tendencies toward proliferation after partial destruction. We can deprive creationism of all intellectual respectability (though not, alas, of some popular appeal) by remembering that sturdy facts are built from widespread patterns and that coherence in structure is the sign of strong arguments and theories. Unconnected, individual items remain shaky until they form a pattern or attain a confidence in individual documentation that neither telegony nor overcoiling—not to mention any creationist claim—ever achieved.

If shaky factual claims were always easy to dislodge, this column could end on a purely optimistic note. But telegony lasted for seventy years, and the ghost of William Jennings Bryan again stalks our nation. If I end with measured optimism, however, I do so in urging that we focus upon the second phrase of what may be Darwin's most famous statement (from the *Descent of Man*): "False facts are highly injurious to the progress of science, for they often endure long; but false views, if supported by some evidence, do little harm, for every one takes delight in proving their falseness."

Stephen Jay Gould teaches biology, geology, and the history of science at Harvard University.

The scientific-industrial revolution is on the threshold of developments from biology as momentous as any that have come from physics—all the way from the steam engine to the computer. For the new science of molecular biology has given rise to a new high technology...

GENETIC ENGINEERING

Under the title of Industrial Microbiology, the editors of SCIENTIFIC AMERICAN have devoted their entire September issue to this single topic.

In this issue, scientists and engineers actively engaged in the work present the full background necessary to common understanding of the new power to manipulate life processes that genetic engineering confers.

These authors review the origins of genetic engineering in the science of molecular biology and place in perspective the industrial application and prospective economic impact of this technology.

Hazards from this new technology must be reckoned with along with benefits. The engineering of life processes implies profound and troubling questions of ethics and value. For years to come, there will be no more authoritative or comprehensive picture of Industrial Microbiology between two covers than that presented in the September issue of SCIENTIFIC AMERICAN.

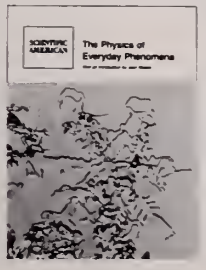
THE ARTICLES

- Industrial Microbiology
- Industrial Microorganisms
- The Genetic Programming of Industrial Microorganisms
- The Microbiological Production of Food and Drink
- The Microbiological Production of Pharmaceuticals
- The Microbiological Production of Industrial Chemicals
- Production Methods in Industrial Microbiology
- Microbiology in Agriculture

With this issue we continue a 32-year tradition of devoting each September issue to a single topic of current scientific and public interest. In the other monthly issues our readers enjoy a diversity of articles covering the full range of disciplines.

All the major advances in science of the past three decades have been reported in our pages by the scientists who did the work. More than 65 Nobel laureates have written for SCIENTIFIC AMERICAN, nearly all of them before receiving the prize.

The collaboration of our editors in the preparation of text and illustration makes the work of our authors accessible to a steadily growing worldwide readership.



Why not join us at the frontiers of knowledge?

A one-year subscription is only $21. A two-year subscription, at $38, saves you $4. And a three-year subscription, at $52, saves $11.

Send no money. We'll bill you.

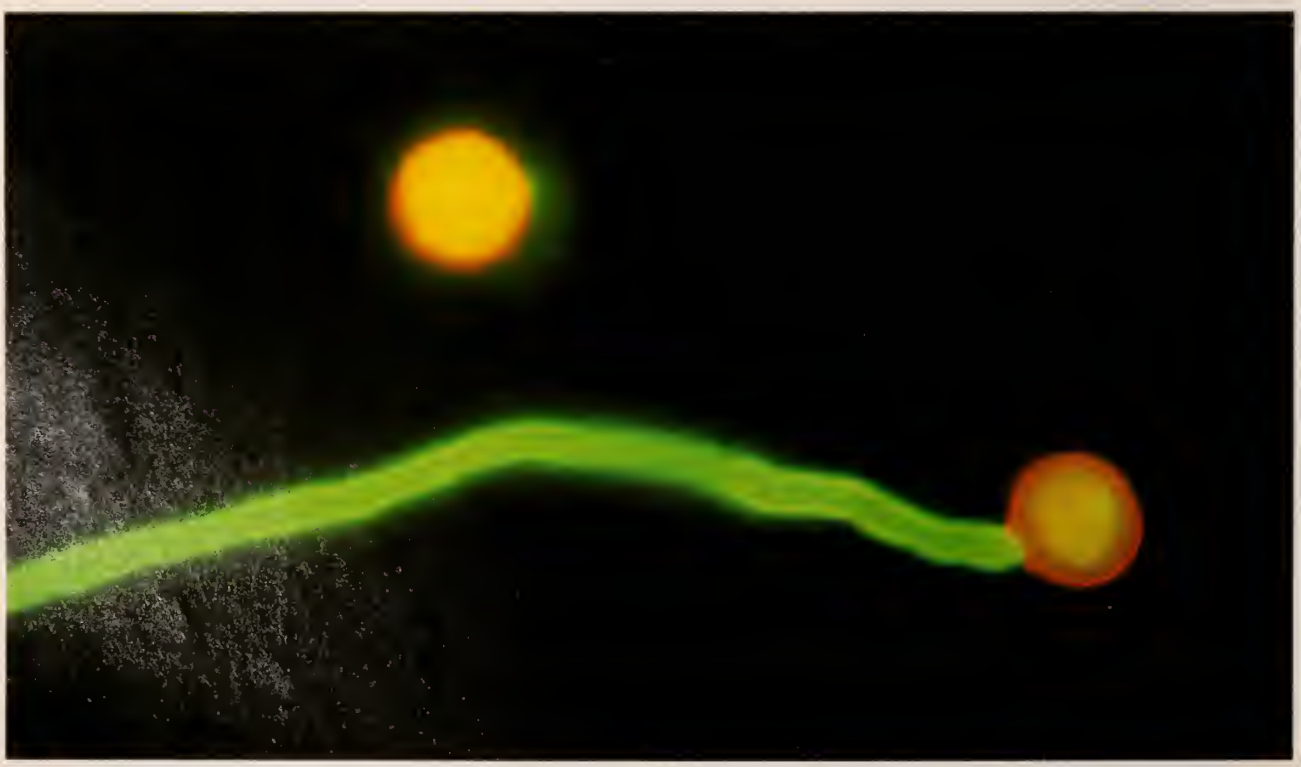
Rise of the Angiosperms



Among the pollen tubes of flowering plants, the race is to the swift and may help explain the angiosperms' success

by David L. Mulcahy

About 125 million years ago, the earth's terrestrial vegetation underwent a dramatic change. At that time, a newly evolved and highly competitive group of plants suddenly rose to dominance. These were the angiosperms, or flowering plants, and they relegated the gymnosperms (most familiar to us as conifers, but also including cycads and the ginkgo) and the ferns to a secondary position. The change was swift, at least in terms of geologic time and, to this day, irreversible. Angiosperms now occupy well over 90 percent of the earth's vegetated surface and, aside from some harvest of marine algae, constitute virtually 100 percent of our agricultural species.

Where did they come from, what were their ancestors, and most intriguing of all, why were the angiosperms able to displace the gymnosperms and the ferns from their position of dominance? We have answers to some of these questions, but to a considerable extent, the rise of the angiosperms remains for modern botanists, as it was for Darwin, an "abominable mystery." Today, in part because flowering plants represent the best hope for increasing agricultural yields and for utilizing the 36 percent of the land surface that is too dry, toxic, or saline to support present crop species, it is more necessary than ever to understand this fascinating group of plants.

On which points are present-day scientists closer to answers than were the Victorians? Thanks to Daniel Axelrod

To bring a touch of Oriental beauty to any room in your home

Custom-designed hardwood wall rack provided for display of the twelve Oriental tea cups. Tea cups shown smaller than actual size of 3¼ inches in height.

The Tea Cups of the Twelve Months of the Year

by Kinuko Yamabe

A collection of twelve Oriental tea cups . . .
each one symbolizing a different month of the year . .
and each portraying the particular flower
which represents that month in Oriental lore.

Crafted in fine porcelain, hand-decorated
in pure 24 karat gold and issued in limited edition.
Advance subscription deadline: September 30, 1981.

In the Orient, as far back as ancient times, flowers were a cherished part of the culture and the everyday life of the people. So universally loved and admired were the exotic flowers of the Orient that each month of the year was designated by a different flower. And that flower was said to symbolize all the virtues of that month.

Inspired by this charming custom, the gifted Japanese artist Kinuko Yamabe has created twelve original designs *exclusively* for a unique collection of tea cups honoring the flowers of the Oriental year.

Each of the twelve tea cups depicts a different flower. For January, the fragile Plum Blossom. For March, the Tree Peony. For April, the noble Cherry Blossom. For July, the Lotus. For October, the golden Chrysanthemum. And for December, the Poppy . . . Twelve exquisite flowers . . . twelve beautiful tea cups.

The artist has followed the ancient "Rimpa" tradition of Oriental art in creating these works—a style which intertwines the real and the imaginary. Thus, there is a hint of mystery about her art—suggesting that each flower has a deeper meaning than its beauty alone.

Each tea cup will be crafted in Japan by artisans whose skill in the porcelain medium is unexcelled. More than 18 different colors will be used throughout to match the variety of shades and tones the artist has used in her designs. Then, as an added touch, each cup will be individually *hand-decorated* with a border of pure 24 karat gold.

Today, Oriental porcelain has become one of the most desired of all forms of decorative art—and is used with any style of decor. This collection is especially desirable because it is exclusive and a limited edition. Yet it is reasonably priced—just $19.50 for each cup.

The advance ordering deadline is September 30th, and the rolls will be permanently closed in May 1982. After that time, this collection will never be available again. Please send the order form below to Franklin Porcelain, Franklin Center, Pa. 19091, by September 30th.

Woodworkers' delight—A subscription to *Fine Woodworking* brings you an abundance of ideas and information on cabinetmaking, carving, marquetry and turning—the tools and techniques, materials and design. Each issue is carefully edited and beautifully printed. Join the 200,000 readers of this superb bimonthly magazine by sending your name and address, along with your payment, to The Taunton Press, 52 Church Hill Road, Box 355CM, Newtown, CT 06470. One year $14, two years $26, refundable. For gifts, please include both addresses. Visa or MasterCard accepted.

of the University of California at Los Angeles we may at least know something about the environment in which the angiosperms evolved and why their appearance was so sudden. His hypothesis is that the angiosperms arose in arid and montainous regions where the ponds and lakes that figure so prominently in the formation of fossils would certainly be rare. Without muddy lake bottoms, which are free of decay-causing oxygen and rich in fine-textured sediments that preserve the form and even the tissues of delicate structures, few fossils would be formed. There would be exceptions, of course, and there are some large lakes in mountainous regions. These lakes, however, would never be filled with the silts and clays that often protect fossil deposits in lowland lakes. Thus when mountainous regions are eroded away, the high-elevation lakes and fossils will go with them, and any traces of life they carried will be destroyed. If the Axelrod hypothesis is correct, the first steps in the evolution of the angiosperms may be lost forever.

The hypothesis also suggests something about the population structure of the ancestral angiosperms. Mountainous terrain is likely to be heterogeneous, and if the regions inhabited by the early flowering plants were arid as well, the plants growing there would probably have been limited to particularly favorable sites. Perhaps the first angiosperm populations occupied only the less arid swales and ravines and were separated from one another by hummocks and ridges. This population structure—a series of medium-sized groups separated by short distances—happens to be the one thought to best provide two requirements of rapid evolution: a good supply of genetic variation and a measure of isolation. The genetic variation contained in medium-sized groups may be adequate to produce individuals adapted to local conditions, but even if it is not, an occasional seed or pollen grain from a nearby group could replenish the stockpile. Moderate isolation would allow this occasional input of genetic material while at the same time preventing a flood of material that would disrupt adaptive gene combinations already present within the population.

The Axelrod hypothesis made a major contribution to the understanding of early angiosperm history, but unfortunately it tells little about how these newly evolved plants were able to outcompete and displace their gymnospermous antecedents. Here we must look to the angiosperms themselves. Their competitive superiority has been attributed to many different characteristics. For example, angiosperms generally produce broader leaves than gymnosperms; this enables the flowering plants to intercept more light for photosynthesis. Angiosperms also produce an amazing arsenal of foul-tasting or even toxic substances that presumably protect them from grazing animals and insects. Furthermore, angiosperms, unlike nearly all gymnosperms, possess vessel elements, specialized conducting cells that form highly efficient vascular systems.

Each of these characteristics has been implicated in the adaptive success of the angiosperms, but none is limited to the angiosperms. Ginkgo, a gymnosperm, produces broad leaves; the resins of the conifers clearly discourage even the most voracious herbivores; and *Gnetum,* another gymnosperm, produces vessel elements, as does bracken fern. Moreover, the more primitive angiosperms apparently lacked vessel elements. Perhaps all these adaptive features are more the products of angiosperm success than its cause. At best, they are probably only a part of the answer. For the rest, let us consider another characteristic of the angiosperms: their mode of pollen transport.

The primitive angiosperms were pollinated by insects, as are most of the present-day angiosperms. (There have been some reversions to wind pollination, but these occurred after the essential features of the angiosperms had evolved.) An intuitive presumption that insects are more reliable than the wind as a means of pollen transport is supported by some excellent studies by Robert W. Cruden of the University of Iowa. He has shown that with insect-pollinated species 6,000 pollen grains may be produced for each ovule, a large ratio but one that pales in comparison with the million-to-one ratio found in wind-pollinated species. This disparity suggests that even if insects consume a great quantity of pollen (up to 90 percent according to some estimates), they are still less profligate than the wind.

In addition, because insects fly more or less directly from flower to flower, they are far more likely than the wind to accomplish pollen transport between such moderately isolated subpopulations as the groups of early angiosperms proposed by Axelrod. The wind can carry pollen for many miles, occasionally covering the decks of ships far

Come share Costa Rica. From the lively town fiestas to the peaceful atmosphere.

Now 50% more for your dollar.

Peaceful Costa Rica is truly a country of contrasts. You can spend your morning walking a secluded beach and experience the thrill of a town fiesta in the afternoon.

If you choose excitement, Costa Ricans always have a reason to celebrate. A Saint's Day, a town fiesta, a bullfight Costa Rican style, or a carnival.

On the other hand, if you would rather escape from the hurrying world, there are plenty of places to get away. Volcanoes. Waterfalls. A jungle train. Peaceful beaches. And you'll experience a gentle hospitality that's hard to find anywhere else.

Three nights accommodations and a city tour start as low as $56 (IT1LR1PF38) per person double occupancy, plus air fare. And with Costa Rica's favorable exchange rate, now you get 50% more for your dollar.

For more information on Costa Rica, call your travel agent or write: COSTA RICA TOURIST BOARD, Box E13, 3709 N. W. 36th St., Miami, Florida 33142.

COSTA RICA

we have so much to share

at sea. As a general pattern, however, pollen grains become widely separated as the wind carries them along, their concentration falling by a factor of 30 million in just 800 feet. This means that beyond several feet from their source, wind-transported pollen grains will be relatively sparse.

If insects are the more dependable means of pollen transport, the issue then becomes one of enticing them to provide this valuable service. The early angiosperms apparently solved the problem by offering insect visitors a meal of pollen, a persuasive inducement since pollen is an extremely rich source of protein. The presentation of a pollen meal was not without problems, however. William Crepet of the University of Connecticut has pointed out that ovules, if they were to receive the gametes of the insect-transported pollen, had to be close to the insect visitors, and ovules are every bit as nutritious as pollen. They are not, however, nearly as abundant. Natural selection apparently favored plants in which ovules were afforded some protection from insect predation, ultimately resulting in the angiosperm ovary, a vessel that completely encloses the ovules. (The word *angiosperm* means "vessel seed"; *gymnosperm* means "naked seed.")

At this point it is possible to reconstruct an interesting (and universal) phenomenon. A problem, in this case the unreliability of the wind as a means of pollen transport, elicits a solution, for example, insect pollination. The solution produces its own set of problems, but unless the solution is no solution at all, these are less severe than the original problem. The secondary problems do, however, necessitate further adjustments in the system: in the evolving angiosperms, ovules had to be protected. Theoretically, this sequence of problems, solutions, and still more problems and solutions continues forever, but in reality, the adjustments probably soon become attenuated to the point of evolutionary insignificance. The important part of this phenomenon is that for many problems, there are several possible solutions. Some of these merely solve the problem at hand, but others may provide capabilities not directly selected for.

The Chinese incorporate an awareness of this duality into their language, using the single word *ji* to mean both "crisis" and "opportunity." In the case of the evolving angiosperms, the unexpected occurred in the third cycle of crisis and opportunity. Enclosing the ovules in protective structures did protect them from insect predation, but it also isolated them from the pollen grains. The solution to this third-level problem lay in the evolution of pollen tubes that could grow from the pollen grains through the intervening protective structures and into the ovules. This solution may have presented the angiosperms with a great opportunity. Consider the fate of the pollen grains of gymnosperms. Carried by the wind, most are lost, regardless of their quality or genetic content. For those that do reach an ovule, the worst is over; developing eggs lie just a few cells away. Even fairly weak genetic types are probably able to complete this final part of the journey. The challenge of this last stage is further reduced by the small number of pollen grains likely to reach any particular ovule, so competition among pollen tubes should be modest.

In contrast, all available evidence suggests that although many of the pollen grains of an insect-pollinated angiosperm are sacrificed to insect nourishment, enormous populations still reach their target, the angiosperm stigma. There they germinate and rapidly produce pollen tubes, which must penetrate the great length of tissue separating them from the ovules. In five to ten hours, for example, the pollen grain of *Petunia* produces a pollen tube whose length is about 900 times the diameter of the original pollen grain. This rate is comparable to a basketball-sized sphere producing a tube about one-fifth of a mile long. Since only a well-balanced and vigorous physiology can sustain such growth, this marathon of pollen-tube development presents a challenge to the metabolic system of the pollen. Furthermore, with insect pollination the number of pollen grains reaching the stigma probably greatly exceeds the number of ovules available for fertilization. This creates an intense competition among the pollen tubes, and only the fastest growing, only the most vigorous will pass their gametes on to the next generation. Therein lies the surprising opportunity for the angiosperms.

Pollen competition apparently provides a mechanism whereby poor genetic types are eliminated and vigorous types preserved. This idea is not new but neither is it universally accepted. Some evolutionists view the extraordinarily intense competition that occurs among pollen tubes as a real danger point in the life cycle of a flowering plant. In 1932, for example, the geneticist J.B.S. Haldane suggested that a gene that greatly accelerates rates of pollen-tube growth will spread in a population even if it has mildly deleterious effects in other parts of the life cycle. "A higher plant," in Haldane's words, "is clearly at the mercy of its pollen grains." Experimental evidence, however, supports a much more sanguine view. Several investigators, beginning with the Russian geneticist D.V. Ter-Avanesian in 1949, have found that in cotton, wheat, corn, tomatoes, petunias, and carnations, gametes from rapidly growing pollen tubes give rise to vigorous plants. Thus, with apologies to Robert Frost, one might say that "good pollen tubes make good plants." It therefore becomes significant that only the angiosperms have a highly effective method of selecting for rapidly growing pollen tubes.

One of the most powerful aspects of pollen tube selection is that vast numbers of individuals are involved, but the system has a qualitative advantage as well. Remember that within plant embryos, seedlings, and mature individuals, every cell (except the gametes) carries two sets of genes, one inherited from each parent. This diploid state has some advantages, chief among them being the ability to store genetic variation, but it has disadvantages as well. Recessive genes, for example, are expressed only when they are carried in all (here both) sets of genes within a cell. Suppose that, by chance, a rare but highly beneficial recessive gene appears within a population. Because it is so rare, there is little chance that it will occur within both gene sets of a cell. The gene, with its beneficial characteristics, will remain unexpressed. Within pollen, however, each cell is haploid and thus contains only one set of genes. Consequently, any gene beneficial to the pollen, even a very rare one, will be expressed within the pollen grain and favored by natural selection. This beneficial gene will increase within the population and eventually reach levels at which both gene sets in some seedlings will carry it. In these respects, pollen grains are similar to bacteria, organisms that exhibit a truly astonishing ability to respond to selection. We have only to consider the ease with which bacteria have developed resistance to many antibiotics in order to realize how adaptable they are. Microorganisms can produce a new generation as quickly as larger organisms can produce a new cell. Thus they can invade any new

habitat or respond to changing conditions with billions of individuals. Also, because microorganisms are haploid, mutations are expressed, and genetic adaptations tested, immediately.

There is another aspect to the potential benefit of a pollen selection system. George Williams of the State University of New York at Stony Brook and V.C. Wynne-Edwards of the University of Sussex have asked what are the contributions that sexual reproduction makes to the process of adaptation. Granting that it provides new and possibly adaptive genetic combinations, they point out that sexual reproduction also has a negative effect. The sexual process takes two perfectly good genetic types (good enough, that is, to survive to, and perhaps through, the rigors of parenthood) and scrambles them together, risking the loss of the good qualities of both parents. Williams and Wynne-Edwards suggest that unless populations are huge, on the order of tens of millions of individuals, sexual reproduction may cost more than it gains. Here is where pollen tube competition may become important.

In both angiosperms and gymnosperms, for each individual that reaches maturity, large numbers of seedlings are started. However intense this selection among seedlings may be, the angiosperms, as we have seen, possess yet another level of selection. Pollen tube competition may mean that the angiosperms, when compared with the gymnosperms, are relatively free to recombine genetic types, and that the selected products of this recombination are quite certain to possess a reasonably well-balanced, vigorous gene set. The gymnosperms, lacking the opportunity for intensifying pollen tube selection, would be forced to adopt a relatively conservative genetic system, one that preserves adaptive genetic types rather than producing vast numbers of new adaptations.

Intense pollen tube competition, an accidental consequence of the shift from wind to insect pollination, may thus have granted the angiosperms carte blanche for genetic experimentation. This evolutionary plasticity may have led early and often to adaptive features, rare or absent within the gymnosperms, that enabled the flowering plants to reach their present position of dominance in the world's flora.

David L. Mulcahy is a professor in the Botany Department of the University of Massachusetts at Amherst.

You never forget your first Girl.

Monkey Moves

Among western red colobus monkeys, females have the freedom to transfer from troop to troop. The males generally don't

by E. D. Starin

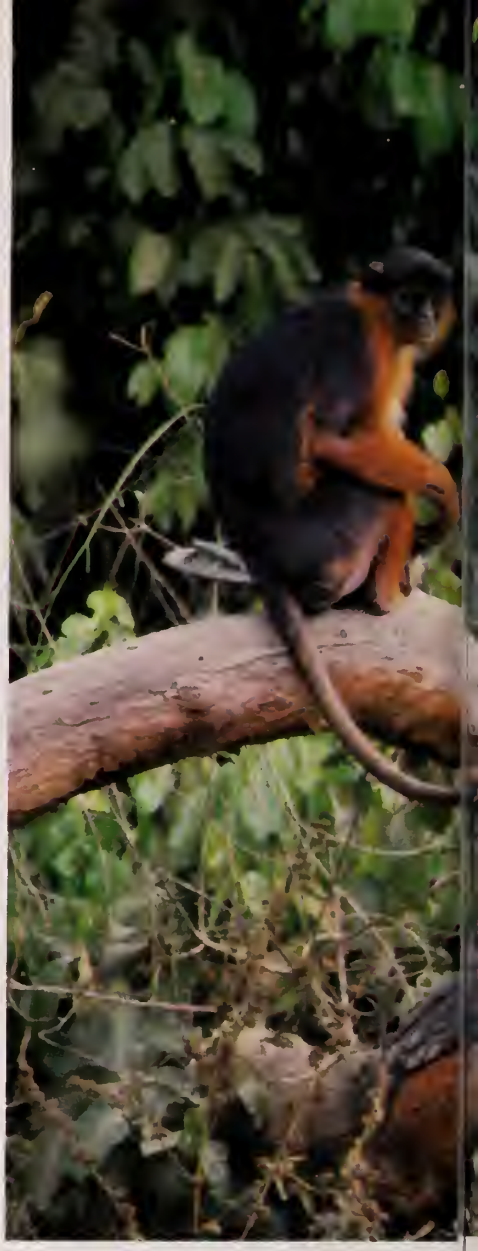
I had spent weeks trying to observe the shy, predominantly arboreal western red colobus monkey in The Gambia's Abuko Nature Reserve, and still could not understand what type of social organization they possessed. For much of the time I saw only a foot here, a tail there, and then a mass of black-and-reddish bodies fleeing through the forest canopy and leaping out of sight. After weeks of not always being able to differentiate females from males, of not knowing whether I was watching one troop or two, I was about to give up trying to concentrate on social behavior when one day the colobus stopped running and hiding and allowed me to follow them throughout their home range.

Red colobus monkeys are spread throughout equatorial Africa, in a variety of habitats from The Gambia to Zanzibar. In The Gambia, they inhabit riverine forest, mangrove swamp, various types of savanna, village perimeters, and infrequently, residential gardens. For the past forty-two months, I have been studying the socioecology of the western red colobus monkey (*Colobus badius temminckii*) in the Abuko Nature Reserve. The reserve, located about twelve miles from the capital, Banjul, comprises some 263 acres of riverine forest; shady, dense raffia palm swamp; sunny, swampy clearings; and various types of savanna. Scattered throughout the reserve's swamps are pools inhabited by both Nile and dwarf crocodiles.

The colobus share the reserve with two other monkey species: the red patas and the green vervet. Although patas and vervets eat some of the same foods as the colobus, there is probably little competition. The patas monkeys live in harems and spend most of their time on the ground in the savanna zones and croplands that surround the reserve. Foraging through leaf litter, patas appear to consume insects and small reptiles, such as skinks—food sources the thumbless colobus would find difficult to harvest. The vervets, on the other hand, are everywhere, utilizing all levels in all habitat zones—from digging holes in the savanna to sleeping, feeding, and resting high in the riverine canopy. Young vervets have even been seen playing and possibly feeding in puddles. Although they eat some of the same fruits, flowers, stems, and young leaves as the colobus, vervets also feed on items not eaten by the colobus: insects, mushrooms, tender grass shoots, palm-nut kernels, tubers, and red ant nests. Although classified as folivores, the Abuko colobus feed on large amounts of fruits, flowers, and seeds. They even consume the odd gall and appear to relish the soil from abandoned termite trails.

The vervets and patas have an essentially neutral relationship with the colobus. In fact, the patas and colobus rarely meet. In forty-two months, I saw patas in the main study troop's home range on only fourteen occasions. Vervets and colobus, however, do occasionally interact. (When a colobus and a vervet of the same size meet on a path, the colobus usually takes precedence. Often, if a small colobus is threatened by a larger vervet, the colobus will either ignore the vervet or it will squeal until a gang of its older associates arrives and chases the vervet off.) While one-and-a-half to three-year-old female colobus frequently seek out nearby vervets for grooming and resting sessions and have even attempted to kidnap newborn vervets from their mothers, young male colobus tend to ignore the vervets. One young male colobus, however, spent more than a year as a member of a vervet troop while he shadowed colobus troops.

There are probably few carnivores in the reserve capable of taking a colobus. The Nile crocodile and the African python do prey on them, however. And while I have never seen colobus being attacked by birds of prey, they give alarm calls at most large birds; one adult female and her two-year-old son even gave alarm calls at a falling three-foot-long leaf, and an adult male gave an alarm call at a low-flying helicopter.



There is a tremendous amount of individual variation in colobus facial features, hair color, postures, and vocalizations—traits that the colobus probably use to recognize each other. And what I found most intriguing were the individual behavioral differences, which in many cases do not appear to be related to gender. After I gradually learned to recognize individuals, it became clear to me that the Abuko colobus do not live in compact troops. Rather, they exhibit a form of "fusion-fission" social organization, that is, like

Aggression is infrequent within a troop of western red colobus. Moments before this photograph was taken, this adult female expressed a threat, but quickly changed to the expression of appeasement seen on her face here.

E. D. Starin

A female pauses with her twenty-day-old infant, above, which will be weaned when it is roughly nine months old. The group of colobus resting calmly on the branch of a tree, right, includes an adult male (center) and an adult female (right). The female's two-year-old daughter (left) will transfer out of her natal troop just before or during her first estrus, which will occur when she is three.

chimpanzees, South American spider monkeys, and hamadryas baboons, colobus troop members form subgroups that separate and coalesce. Moreover, it soon became apparent that all females and most males leave their natal troop, that the two sexes display very different behaviors when transferring between troops, and that males attempting to enter a new troop are sometimes killed.

While female transfer may be unusual for nonhuman primates—only gorilla and chimpanzee females are known to regularly transfer between social units—it may be a general red colobus trait. Researchers studying red colobus in the Kibale rain forest in Uganda and in the gallery forest along the lower Tana River in Kenya also found that females are the most mobile individuals. It is not yet clear, however, whether the continual separating and coalescing of individuals and the killing of intruder males are species-specific traits or adaptations to the specific ecological, demographic, and social conditions of Abuko.

Most red colobus in the Abuko reserve live in mixed social units, called troops, of about twenty-three individuals. At present, my main study troop has nine adult females, two adult males, seven subadults and juveniles, and five newborn infants. The surrounding troops,whose home ranges overlap extensively with that of the main study troop, show similar compositions.

Each troop consists of individuals that associate together frequently and peacefully and share a common home range. Older individuals take precedence over younger ones, and mothers will defend their young, but aggressive interactions between resident troop members are infrequent. What intratroop conflict occurs generally takes the form of facial and vocal threats and rarely entails fighting. Frequently, a threatening facial expression is quickly transformed into an appeasement expression and a grooming bout ensues. Because of the rarity of agonistic interactions, the frequency of friendly behaviors, and a weakly defined adult-dominance hierarchy in which the resident males and females actively cooperate to repel some intruder males, it appears that dominance–subordinance relationships are not too important in maintaining harmony within the troop.

Troop members frequently separate and reunite. Sometimes up to three separate groups are formed, and these subgroups can remain apart for days at a time. The colobus pattern differs from the observed fusion-fission of chimpanzees, hamadryas baboons, and spider monkeys in that colobus spend more time together as a troop, and resident adult males seldom wander off alone or in a group. Resident adult males in their prime are normally with at least one female. Resident colobus females, however, have been observed to wander off alone. And old adults of both sexes wander off alone before they die. Because of this fusion-fission, mothers can be observed in different subgroups from their unweaned offspring for days at a time. (After they are nine months old,

colobus offspring can get along without milk. One female was orphaned when she was nine months old, and while she did not need her mother's milk, she probably did need a protector. Her older sister adopted her and was extremely possessive and protective toward her, much more so than any mother would be. This restrictive "sistering" probably reduced the chances of falls, kidnapping, and predation, but it also probably contributed to the orphan's obviously slow social development.)

The continual separating and reuniting of troop members takes place throughout the year, probably for a variety of reasons. The fluidity of the troop allows each member to move freely and thus avoid aggressive interactions. During the mating season there is much helter-skelter movement; boisterous, highly visible nondirectional displays by estrous females are frequent; and intermittent, aggressive intertroop encounters and male–male harassment take place. During this period it is not uncommon for old females and pregnant and lactating females with their dependent offspring to absent themselves from the males and estrous females. Such females and their young would have little to gain by getting involved in intertroop encounters at this time.

Fusion-fission is more apparent during the mating season, but because it also occurs during the rest of the year, it can be viewed as a response to the density and dispersion of resources. When a major food source is heavily clumped and can support many feeders, the entire troop will frequently feed together. When the major food source is widely dispersed or when there are many major food sources available at the same time, the feeders tend to break up into various subgroups throughout the range, thereby minimizing competition and maximizing the amount of range monitored. Because they are spread over a larger space, the colobus see more of the range and possibly learn about the availability of food sooner.

While the size and composition of each subgroup is not stable and endless combinations of individuals occur, there are some common patterns. Members of the same subgroup tend to be close associates. Some females have very close relationships with each other. They groom frequently, huddle together, and their offspring are playmates. They will defend each other

E. D. Stann

E. D. Stann

An adult female red colobus grooms an adult male green vervet, above. Such grooming bouts are a frequent sight in The Gambia's Abuko Nature Reserve, where the vervets are ubiquitous. Red colobus males may even join a group of vervets while shadowing a colobus troop that they want to transfer into. Other types of interactions between the two species, such as the scene at right, are rare.

against females from outside their subgroup and will even defend each other's young. Other females, however, rarely interact. When subgroups of female associates form, they tend to use the same area of the range continually, and these favorite areas tend to be in overlapping troop zones. Close associations and the use of favorite areas may occur because all females transfer out of their natal troop. When females that are age-mates and thus not sisters (or at least do not have the same mother, although they may have the same father) transfer into the same troop, they tend to spend the majority of their time together. When these females wander off as part of a subgroup, they tend to go to areas where their present troop range overlaps with their natal troop's range. Why they return to these areas is not clear. They do not interact peacefully with any of their previous troop mates. In fact, they either ignore, threaten, or flee from individuals they once associated with peacefully. They may be monitoring the resource situation and social setting for a possible return. It is not yet clear whether females ever return to their natal troop for an extended period. Certainly some females transfer more than once. One subadult female joined the study troop during estrus, transferred to a neighboring troop for the birth of her son, and then returned to the study troop with her month-old offspring. Another adult female accompanied her prepubescent, subadult daughter to a neighboring troop, stayed with her for a week, and then returned to the study troop.

Females transfer voluntarily and successfully. They do not spend time as solitaries shadowing other colobus troops; rather, they tend to transfer during intertroop encounters. A few months before transferring, a female's behavior changes. She begins to seek out vervets for resting and grooming sessions, and eventually she will head off in a direction opposite from the troop. An adult male usually runs after her. The male will not attempt to herd her, but will make a number of friendly gestures, such as mounting and grooming. So far, however, I have not seen a male successfully entice any young female to stay in her natal troop. All of the females known to have been born into the main study troop have left either before or during their first adolescent sexual swelling, which occurs during their third year.

When a female transfers, she is accepted by the males and the subadult and juvenile females in her new troop. She will usually be chased and receive threats from some of the resident adult females. These differing reactions are to be expected since the female will be a potential mate for the males and a potential competitor for resources with the other females. Because juvenile and subadult females will soon be leaving the troop, they will gain if the new female stays in their natal troop, instead of transferring again, possibly to become a potential competitor in their new troop. Although all females leave their natal troop, they are replaced by

young females from other troops, and so this practice has little effect on troop size and composition.

Young males also leave their natal troop, but the process is not voluntary and it can be unsuccessful. As young males matured in the study troop, they were basically ignored by the resident adult males but harassed by a three-year-old native male. After much harassment by this male, all three juvenile males left the study troop and began to travel on their own, generally avoiding their natal troop. One young male that returned for a day was continually threatened by the three-year-old male and virtually ignored by most of the other troop members, except for his mother, who spent the entire day and probably most of her energy trying to defend him from the harassment of the three-year-old native. This is in direct contrast to a young female that returned for a day. She was enthusiastically greeted, groomed, and invited to play.

Two unsuccessful male transfers took place during the study. In one case, an adult male joined the troop for one month. During this time he avoided the resident males, threatened the juveniles, and frequently ran into the center of a resting group, mounted a female, then ran off. After one month of avoidance, bullying, and "sneaking" copulations, he was attacked and killed by two of the resident females and one of the resident males. In the other case, a large subadult male shadowed the study troop for a few days and then walked into the center of the troop where he was groomed by the juvenile females. After an hour of what appeared to be acceptance, he was viciously attacked by at least seven of the resident females and one of the resident males. When my proximity to the incident brought the attack to an end, the male had severe wounds on his body and was bleeding profusely. Barely able to move away, he had lost one eye and probably died shortly after. In both of these attacks, the victim was pinned to the ground and the attackers bit furiously. In another case, I heard a loud uproar from a neighboring troop, and when I reached its territory, found a dead, twenty-three-month-old male that had been expelled from the local troop. The severe bites on his body looked as though they were inflicted by colobus canines. While it is not uncommon for a subgroup of lone females to

World Wildlife Fund, M. Bijleveld

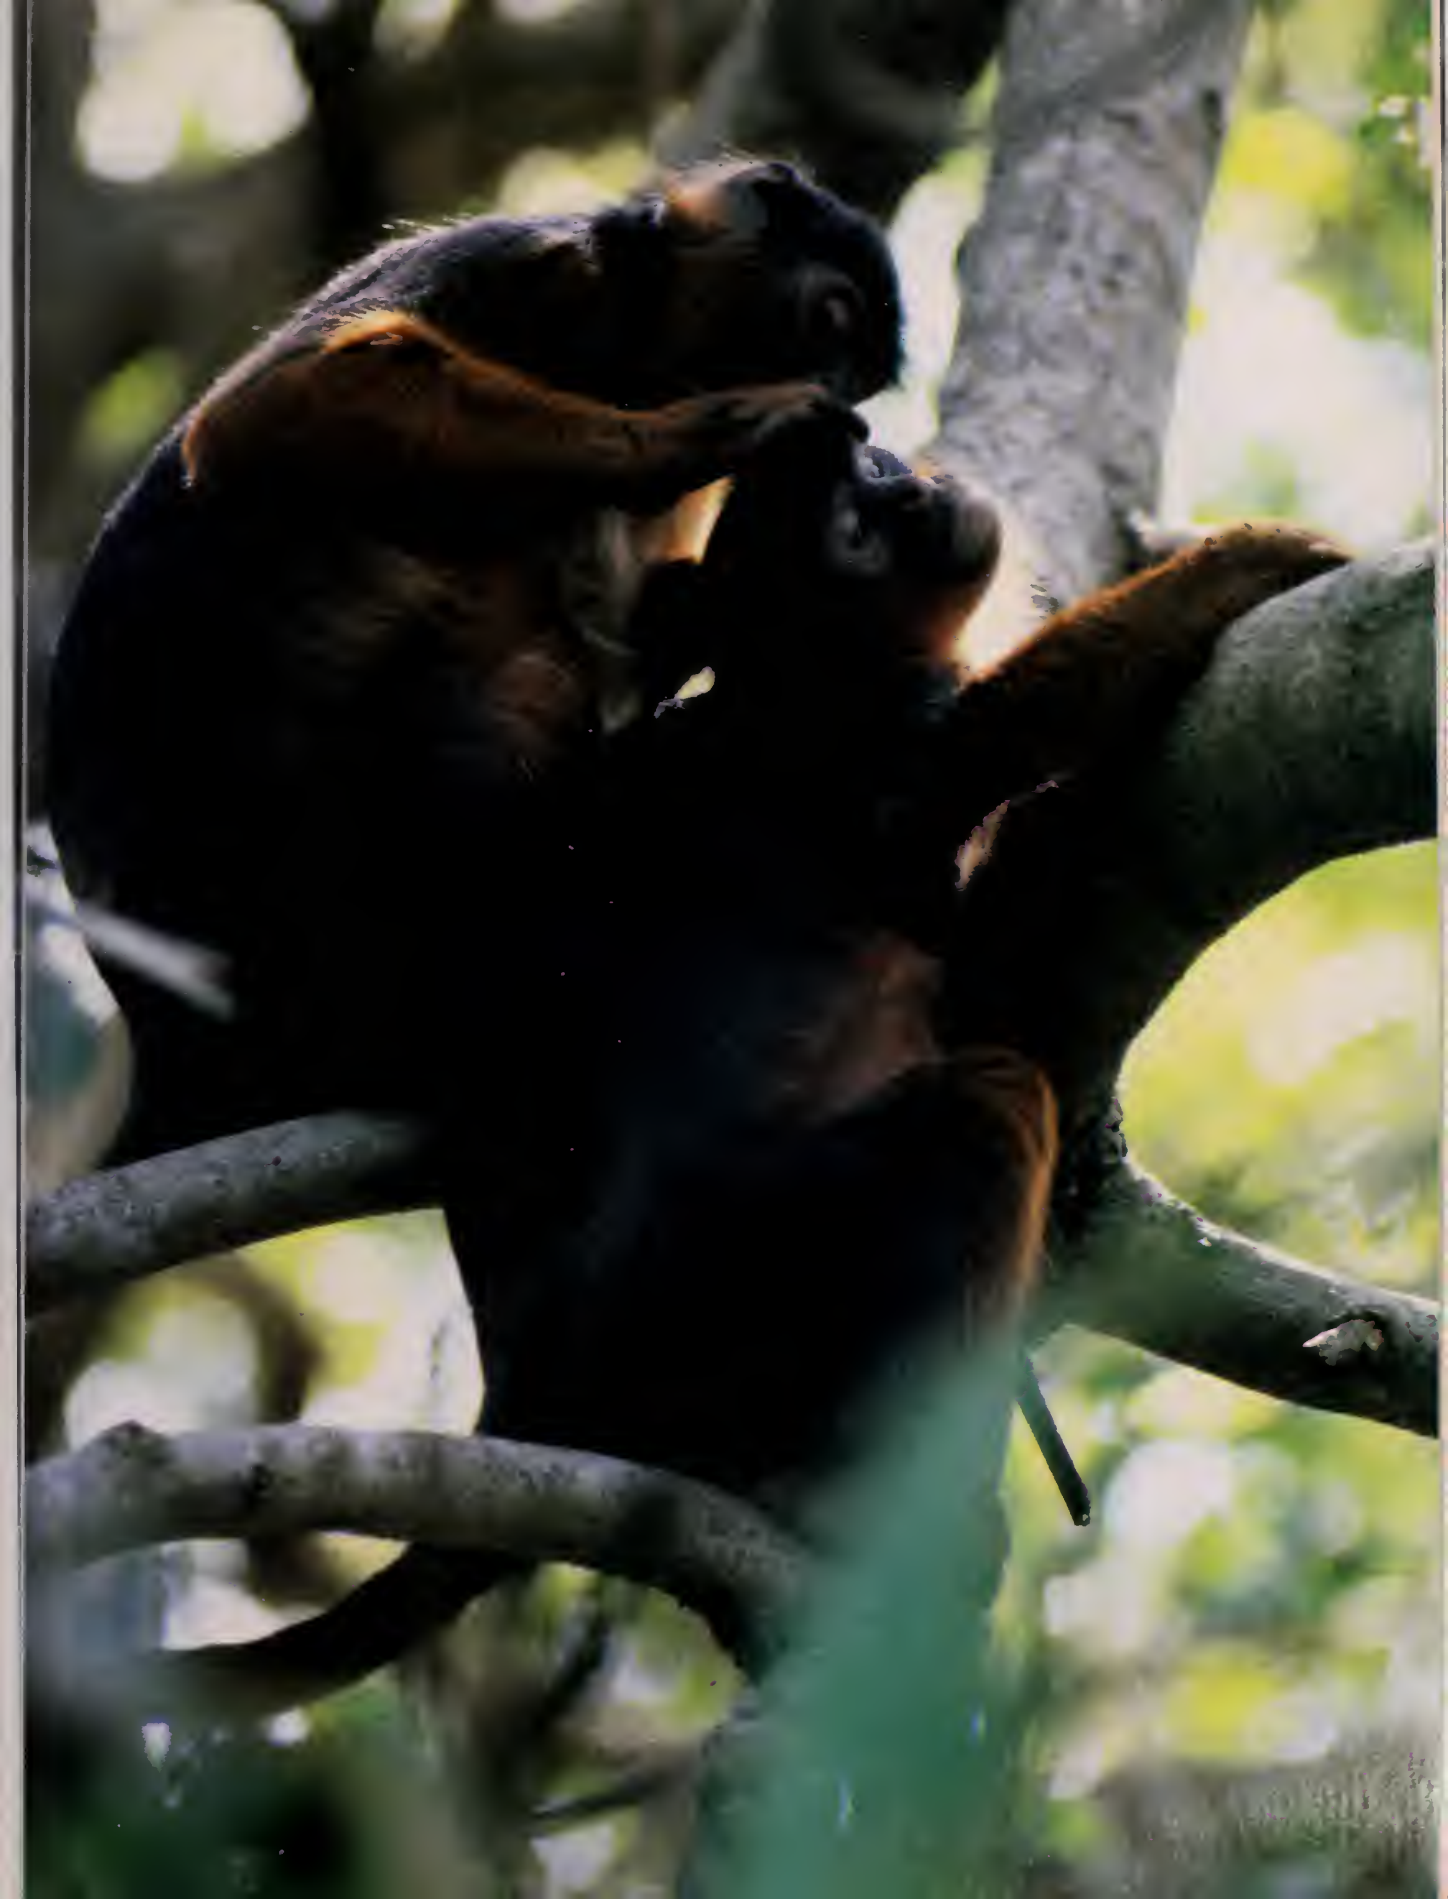
Pools and swamps in the Abuko reserve, left, are inhabited by Nile crocodiles, predators of western red colobus. The young pregnant colobus, right, is engaging in a grooming bout with a 3½-year-old male.

threaten and give chase to strange males, strange males have not been observed threatening and chasing resident females. In fact, one strange adult male, while being chased off by the local troop, gave frantic appeasement gestures to a resident adult female that ignored him.

I did witness one successful male transfer. A young subadult male spent more than a year as a member of a vervet troop, shadowing both the study troop and a neighboring troop. After one of the two resident males in the neighboring troop disappeared, this young male successfully joined the troop and has now been resident for one year. There is also a very old adult male now living on the periphery of the local troop's range. While he occasionally meets up with an exiled thirty-two-month-old male from the local troop, he spends most of his time alone, moving slowly on the forest floor, avoiding all contact with mixed groups.



The methods and results of transferring show clear sexual differences. This suggests that the troop has very different meanings for females and males. A colobus female probably views a troop as an open unit that she can easily investigate and, if she chooses, can join. If she decides that another troop would be better, she switches. The decision as to what troop she will join appears to be entirely up to her. Her allegiance to her present troop is intense, but she is liable to make a quick switch. This may be why males rarely display aggressive behaviors toward females, for there is always the possibility that if life gets too rough, a female will simply pick up and leave. Certainly, males do not normally dominate females, and it is often apparent that males go out of their way to engage females in friendly behaviors.

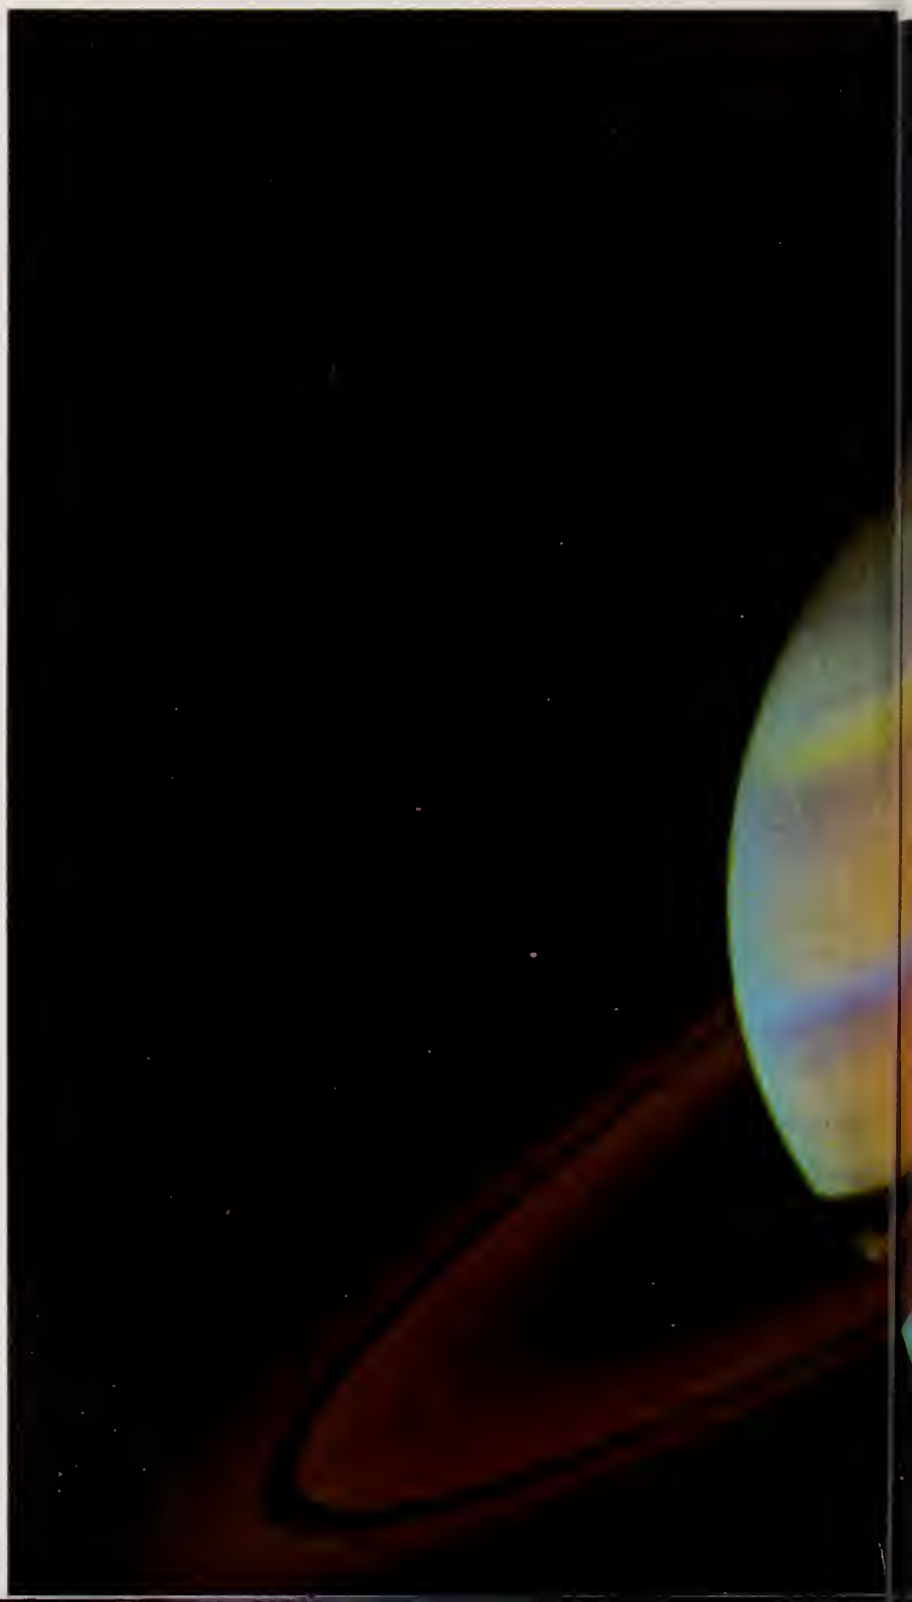
A nonresident colobus male probably sees a troop as a fairly closed unit, which he can only investigate from afar and cannot easily join. The decision as to whether he will join a troop is not up to him alone. Rather, it is a decision probably made by the resident troop members. If he is able to stay in his natal troop or make a successful transfer, his allegiance, like that of the females, is also intense. Once in a troop, he will use all his persuasive powers to try to get as many females as possible to remain with him.

In the literature, there are frequent statements that transfers between troops occur in order to eliminate the possible deleterious effects of inbreeding. If this were the only reason for transferring, then only one of the sexes would have to relocate. Both sexes leave the natal troop, however, so it must occur for another reason or, more likely, a number of reasons.

Clive Marsh, who studied the Tana River red colobus in Kenya, has suggested that the function of female transference may be related to mate choice and the avoidance of infanticide. This suggestion appears to hold true for the Abuko red colobus population. Many of the more interesting behaviors—the killing of intruder males, particularly by adult females; the ease with which females can investigate troops; the difficulty males have in gaining access to troops; the chasing off of strange males by females; and the rarity of aggression displayed by resident adult males toward females and their offspring—may also be related to choosing mates that are not potentially infanticidal. It may not be mere coincidence that both observed attacks were led by females, that no mother with dependent offspring was seen anywhere near an intruder male, and that all partly weaned young ran off and quietly hid for the duration of the attacks. Females may well be able to judge which males will be promising mates and which are potentially infanticidal, and act accordingly.

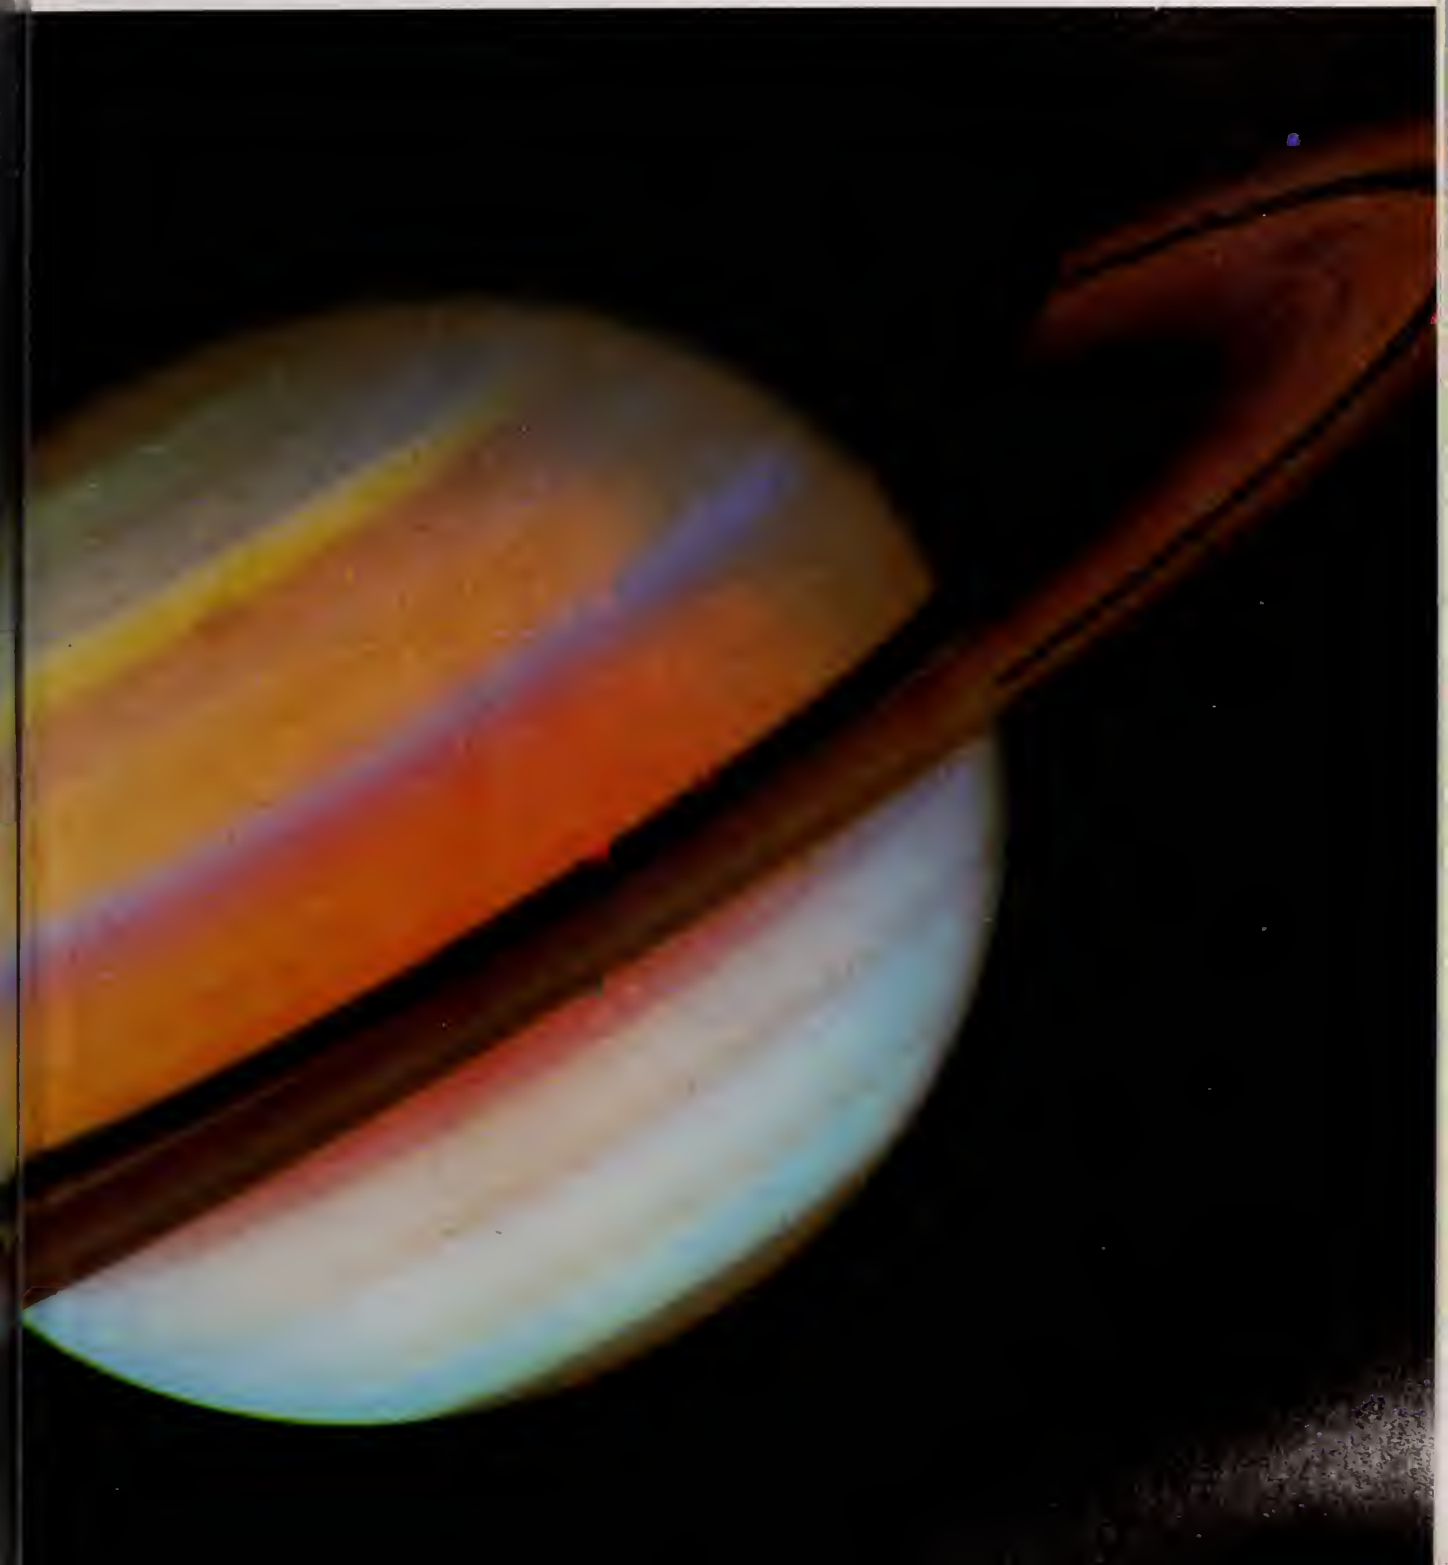
Although we now know that red colobus display a form of fusion-fission organization, that females voluntarily leave their natal troop, that males are usually expelled, that females transfer easily and successfully between troops, that males encounter more difficulties in joining a new troop, and that intruder males are sometimes killed, the colobus puzzle is still partly scrambled. Do grandmothers ever meet their grandchildren? Does a younger sister join the same troop as her older sisters? Does the mother's behavior determine whether her son will remain in the troop or leave? Do expelled juvenile males return to their natal troops when they reach adulthood? Is female friendship based solely on a common natal troop experience? How closely related are female associates? Why are some intruder males killed and others accepted? What is a female investigating when she enters a new troop? Why do some females transfer over and over again and others perhaps only once? In light of the current interest in reproductive strategies, male and female behaviors, and kinship theories, the red colobus are very intriguing and appropriate animals to study. □

Saturn's Surprises



Unpredictability was the only predictable aspect of the data sent back by the Voyager 1 *spacecraft from this giant planet*

by Andrew P. Ingersoll



Scientists awaiting the *Voyager 1* encounter with Saturn in November 1980 were concerned that the second giant planet might not be as interesting as the first (see "By Jove," *Natural History*, May 1980, describing *Voyager*'s encounter with Jupiter). Saturn's famous rings might be featureless. The surfaces of its satellites might reveal no record of geologic activity. A uniform haze might hide the colorful swirling clouds on the planet. And the atmosphere of Titan, Saturn's largest moon, might prove to be disappointingly thin. But Saturn was not a disappointment, its richness proving once again that new worlds are worth exploring.

As planets go, Saturn and Jupiter are in a class by themselves. They are not massive enough to be stars, although they are made of the same elemental mixture that makes up the stars and the sun. They shine by reflected light, as the other planets do, yet they also emit appreciable amounts of stored internal energy. Like the sun, they are gaseous objects without solid surfaces on which to land a spacecraft. Saturn is less massive than Jupiter and colder. Both have rings and more than a dozen satellites. Together they account for more than 90 percent of the solar system's mass outside the sun. And the study of these great planets not only teaches us about our own world and its history but also allows us to test our model of solar system formation.

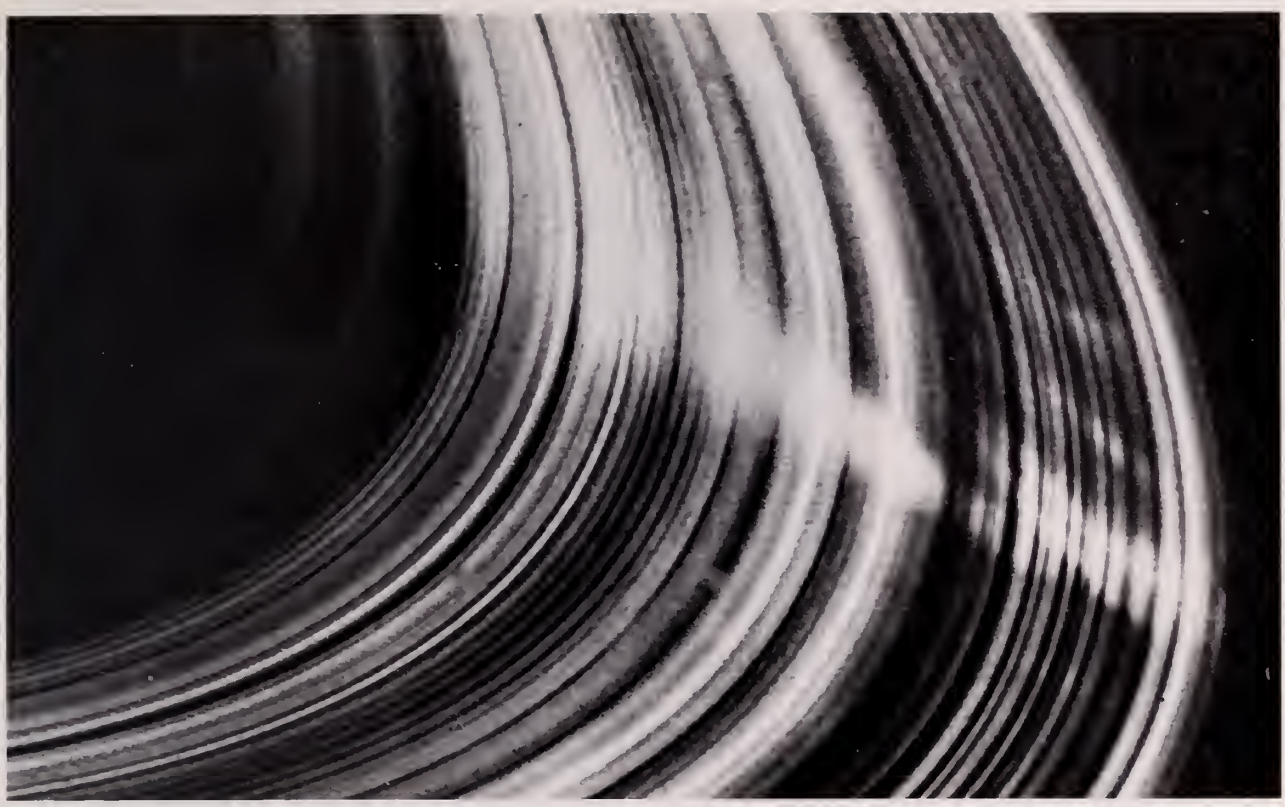
Perhaps the most interesting and special feature of Saturn is its system of rings. These are not solid sheets but billions of particles, small satellites, in fact, orbiting around the planet. Long ago, collisions between the particles eliminated most out-of-plane motion as well as motion toward and away from Saturn. Thus, from afar the rings appear perfectly flat and circular. Earth-based observations suggest that the particles range from one to ten feet in diameter and have water-ice surfaces. Several rings are visible from the earth. Starting farthest from Saturn, these are the A ring, followed by a narrow, semitransparent "gap" called the Cas-

Photographs from NASA

sini Division, then the almost opaque B ring, and finally the semitransparent C ring closest to Saturn. The Cassini Division is named after the seventeenth-century astronomer who discovered it. This gap is thought to represent the perturbing effects of Mimas, Saturn's innermost large satellite, which completes one orbit as the particles in the gap complete two orbits. One or two other gaps had been seen from the earth, but little else about Saturn's ring structure had been seen or could be anticipated.

Hence the structure viewed by *Voyager* came as a welcome surprise, providing information on which to test theories of ring origin and evolution. Instead of two gaps there were hundreds. Rings (or ringlets) appeared within the rings, almost without limit as the resolution of the *Voyager* images improved. The Cassini Division, itself a huge structure as wide as the North American continent, was found to have gaps and rings down to ten miles wide. Only a narrow zone where the orbital period of a hypothetical particle is exactly one-half that of Mimas was found to be truly empty.

A simple fractional relationship between periods, such as exists between the Cassini Division and Mimas, is called a resonance. According to theory, whenever ring particles are resonating with a nearby satellite they begin to swing back and forth, nearer and farther from Saturn. The effect is like pushing a swing. The push can come every time the swing returns to its highest point or every other time or with more complicated regularity. But if the push is large enough, the swinging will increase. Mimas exerts a gravitational pull, not a push, on the particles in Saturn's ring structure, but the net result is the same. The swinging of ring particles in their orbits causes the particles to collide. The places where the swinging amplitude is largest, where there are resonances, are cleaned out by collisions. The trouble is that the known satellites have only a few strong resonances, not enough to explain the hundreds of observed gaps.



The current view is that there are hundreds of unseen "pushers" hidden in the rings. These might be objects one to ten miles in diameter, orbiting alongside the one- to ten-foot-sized objects known to be present. In *Voyager* images such tiny satellites would be barely detectable against the blackness of space. They can apparently escape detection by hiding among the smaller bodies. Nevertheless, their existence is reasonably well established, forcing us to consider a much wider size range for the ring particles.

The existence of ring particles in the one- to ten-foot range can be inferred from the way the rings scatter radio waves at these wavelengths. The presence of much smaller particles, of the order one ten-thousandth of an inch, was revealed by *Voyager* observations of the way the rings scatter sunlight. Clearly, different processes control the abundance of objects in these very different size ranges. One theory that now looks attractive is that Saturn's rings are the remains of a satellite or group of satellites that broke up, rather than a satellite that never formed. Gentle collisions within a cloud of particles tend to produce a more uniform-sized distribution, but violent collisions of large objects tend to produce both large and small fragments.

An important concept for the study of rings is the so-called Roche limit, which defines where an orbiting object can hold itself together under its own gravity. For example, a shovelful of sand in empty space will evolve into a

Voyager *images revealed that two of the three strands in Saturn's thin, outermost F ring are twisted and braided. The cause of this phenomenon has yet to be explained.*

Radial, spokelike features were seen crossing the ringlets of the B ring at nearly right angles. These features, which scatter sunlight in the manner of small particles, may be associated with electrostatic discharges.

spherically shaped object. But if the sand is orbiting close to an object such as Saturn, the grains closer to the object will tend to orbit faster, and the sand will spread out, first into a ring and then into a disk. At some distance from Saturn the two effects balance, and a pile of sand orbiting there would just barely hold itself together under its own gravity.

The Roche limit for Saturn is somewhere beyond the outer edge of the A ring. Inside this radius, a fragmented satellite would not re-form, and a cloud of dust grains would not aggregate. It is significant that the three known planetary ring systems, those of Jupiter, Saturn, and Uranus, are all within the Roche limits of their respective planets.

Outside Saturn's A ring but close to its Roche limit, there are at least five small satellites and a thin ring, called the F ring. The outer two satellites in this group share the same orbit and seem to change positions slowly so as to avoid collision. Two more of the satellites seem to "shepherd" the newly discovered F ring, one orbiting just outside this thin filamentary feature and one just inside it. Closer to Saturn, the fifth of these small satellites orbits just outside the A ring and seems to push it inward. These satellites and rings would be expected to interact and eventually collide. Indeed, the two coorbital satellites may be fragments from a collision long ago, but their orbits have evolved so that the two objects now avoid each other. Similar repulsive behavior also characterizes the interaction between the shepherding satellites and the nearby A and F rings. All of these satellites repel ring material, forcing it inward or outward, away from their orbits. This repulsion seems paradoxical, since the force of gravity is attractive. Such apparent paradoxes, however, are common in orbital mechanics; forces tend to have effects that are opposite to expectations based on everyday experience. For example, a force that acts in the direction of motion causes an orbiting body to move outward, where it orbits more slowly. A backward force eventually causes the body to orbit faster.

Thus, near the Roche limit this tendency of objects to avoid each other seems to interfere with the process of aggregation or reaggregation of individually orbiting bodies. Farther out, the constraints of orbital motion are less important than mutual attraction, so the aggregating effect predominates. In general terms, this is why the regions well outside the Roche limits are so empty. During the final phase of planetary formation, bodies there collided and stuck to one another, held together by their own gravity. The large satellites that remain in these empty regions must have swept up all the original material. The same sweeping process seems to describe the formation of the planets in our solar system from the original gas-dust cloud that was orbiting the sun during its formation.

Another curious feature is the radial spoke pattern that appears in the middle of the B ring, crossing its circular ringlets at nearly right angles. Like everything else in the rings, the spokes orbit Saturn, but they change shape, disappear, and re-form with each orbit. They scatter sunlight in a manner characteristic of small particles, those with sizes comparable to the wavelength of light. Electrical forces can be important for these particles, and so the spokes may be associated with the unusual radio signals detected by *Voyager*. The available evidence suggests that the spokes are related to electrical dis-

The top half of this composite photograph shows Saturn's rings as seen from the northern, or sunlit, side. The bottom image shows the same rings viewed from the southern, or unlit, side. The thick, opaque portions of the rings appear bright when viewed from the north and dark when viewed from the south. Conversely, the thin, semitransparent parts of the rings appear dark when seen from the north and bright when seen from the south. These images were made by Voyager 1 *in November 1980, when the spacecraft was approximately 1,898,000 miles from Saturn.*

charges, in which charge built up by the motion of ring particles through Saturn's magnetic field suddenly flows radially. The sparks created by the electrical discharges would be made visible by the motion of small particles out of the ring plane. Right now, it is not known whether the spokes are just another curious feature of Saturn's rings or whether the associated electrical forces play an important role in ring structure and history.

Electrical forces have also been invoked, partly in desperation, to explain another puzzling phenomenon, namely the intricate structure in Saturn's thin F ring, located just outside the A ring. The F ring contains three intermittent strands, two of which appear to be twisted. The instantaneous shape of the strands does not follow a simple orbital trajectory, so perhaps the whole pattern of kinks and braids orbits Saturn together. But then why doesn't the structure spread into a more conventional flat ring? Once again, hidden satellites embedded in the ring structure may provide the answer. Electrical forces may also be important, since much of the F ring structure is revealed by scattering from small particles.

Moving outward from the rings and small satellites, we encounter the larger satellites Mimas, Enceladus, Tethys, Dione, Rhea, Titan, Hyperion, and Iapetus. Except for Titan, whose diameter is 3,000 miles, all have diameters from 180 to 900 miles; all these satellites have densities close to that of water and are at least partly covered by water ice. Considering their small size and similar compositions, the surfaces of these satellites are surprisingly different. Mimas has a single large crater, with a diameter one-third that of the satellite. The impact of the collision that created the crater must have come close to breaking the satellite apart and was probably capable of melting a portion of the crust, causing substantial resurfacing. The absence of intermediate-sized craters probably indicates that at least one such resurfacing occurred after the final heavy bombardment during satellite accretion. Enceladus was not visited by *Voyager 1*, but viewed from across the Saturn system it appears to be almost featureless. It is also the brightest of the icy satellites. Tethys has a density almost equal to that of water. A long deep valley on the surface of the satellite implies geologic activity at some time in the past. Dione and Rhea both have bright, wispy markings on their dark, trailing hemispheres, the "protected" sides in their orbital motion around Saturn. These markings suggest that a low-density material, probably ice, was forced up through fissures in the surface. Bombardment of the leading hemispheres has since removed the markings from the front sides. Dione has a low overall crater population, with a flat, plainslike surface that must have come after the heavy bombardment phase so as to cover any preexisting cratered terrain.

Basic questions about these five icy satellites are, Why do they have such low densities (implying that they are mostly water ice)? and Why are they so small in relation to Jupiter's four Galilean satellites? The answers may lie in the difference in mass between Jupiter and Saturn. Saturn, being less massive, did not contract during its formation as soon as Jupiter, and so may have incorporated more of the late-arriving satellite material. Jupiter, contracting sooner, may have left more satellite material in orbit. Also, Saturn's early temperatures were never as high as Jupiter's, so that water was not evaporated away as it was close to Jupiter. These ideas are supported by computer models of a collapsing cloud of planetary material.

Saturn's giant satellite Titan is a unique object. Larger than our moon, it is the only satellite in the solar system known to possess an atmosphere. Its bulk density is consistent with a rock-ice mixture. The surface of the satellite is entirely obscured by a dark haze of extremely small particles. Before *Voyager* got there, the only gas known to be in Titan's atmosphere was methane (CH_4). The satellite's surface pressure and possible other gaseous constituents were unknown. The "slowing down" of *Voyager*'s radio signal as the spacecraft passed behind Titan made possible a determination of surface pressure. Infrared and ultraviolet spectra taken by *Voyager* established the abundance of gases. Titan's atmosphere turned out to be mostly nitrogen (N_2), like the earth's. The mass of an air column at the surface is more than one-tenth that on Venus and over ten times that on the earth. The speed and direction of the winds are unknown, but there is a faint pattern of colored clouds arranged in bands.

It is remarkable that all planetary atmospheres, including Titan's, are made primarily of the same four elements: carbon (C), hydrogen (H), oxygen (O),

and nitrogen (N). The differences are due mainly to the mass of the planet and its proximity to the sun—in other words, its temperature. The giant planets—Jupiter, Saturn, Uranus, and Neptune—retain all those four elements, including abundant amounts of hydrogen, and so the other three elements appear as methane (CH_4), water (H_20), and ammonia (NH_3). The terrestrial planets and Titan, by contrast, are not massive enough to retain hydrogen, which is the lightest element and therefore tends to escape. With oxygen available in the form of water, the terrestrial planets converted carbon to carbon dioxide (CO_2). On Titan water is frozen and inert; therefore, carbon must have combined with itself to form hydrocarbons. These condense to form the dark haze particles that fall to the surface. As on the terrestrial planets, nitrogen remains in the atmosphere as N_2 but no water or oxygen enters the picture. Methane gas could condense to form snow and rain on Titan, however, and liquid methane oceans could conceivably exist at the surface. In this sense, methane is the "water" of Titan.

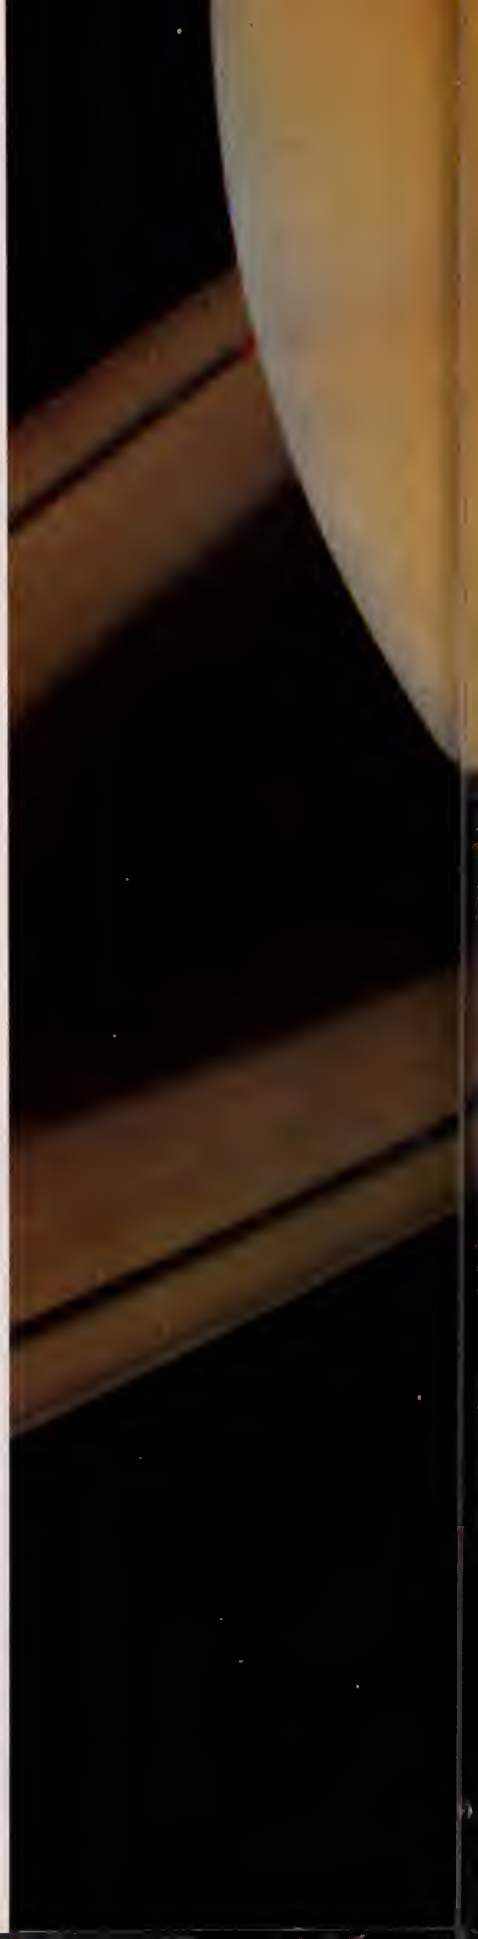
Thus Titan followed an evolutionary path different from that of the earth, largely because of its much lower temperatures. Mars and Venus also had different evolutionary paths, again because of temperature. Current belief is that the earth is probably the only object in the solar system capable of holding liquid water, and therefore probably the only object where life could have evolved.

Hyperion and Iapetus complete the list of Saturn's "regular" satellites, those in circular orbits all in the same plane. They seem to be icy objects, like the inner five, and are also smaller than massive Titan. Iapetus is curious because of the fivefold difference in brightness between its bright, leading hemisphere and its dark, trailing hemisphere. Again, water ice is a candidate for the bright material, which has the reflectance properties characteristic of ice. Saturn and Jupiter also have small "irregular" satellites in huge, inclined, eccentric orbits. Theory suggests that these are captured objects, as distinct from the inner satellites in their flat, circular orbits. The former group are loosely bound to their parent planets, and their present orbits could have evolved after the formation of Saturn. The regular inner satellites must have formed with Saturn in nearly their present orbits.

Saturn itself provided some nice data for the *Voyager* spacecraft. The colors in the atmosphere are more muted than those of Jupiter, and there are fewer large, oval structures such as the Great Red Spot. But the banded cloud pattern is prominent, and the associated winds are remarkable. Winds are measured relative to Saturn's internal rotation, which we can sense by looking at the magnetic field. Winds at the equator flow eastward at more than 1,000 miles per hour. Jupiter's equatorial winds are only one-quarter this speed. Other differences between the two planets are not so great, making the difference in wind speeds hard to explain. Both are fluid objects, with no solid surfaces for winds to rub against; hence it is easy to imagine high winds on both planets. There is currently a debate over how deep the winds go, that is, whether they extend through the interior to the core of the planets or are confined to the thin layer where sunlight is deposited and radiation is emitted. This is a debate between astronomers and meteorologists over whether the giant planets resemble stars more than they resemble earth.

A curious feature of the winds on Jupiter is that turbulent eddies contribute energy to the east–west currents, not the reverse as one might expect. The ed-

This photograph, taken as the Voyager *spacecraft traveled past Saturn and away from the sun, shows the planet as a crescent, with its shadow falling on the rings. The dark, narrow band in the rings is called the Cassini Division. The lower part of the crescent is visible through this band, or gap.*



dies must get their energy from buoyancy, derived either from internal heat or sunlight. This backward transfer of energy from chaotic eddies to organized currents is also observed in the earth's weather patterns, although it is a minor feature of the total energy cycle. *Voyager* measurements show that on Jupiter, however, this backward transfer is a major part of the energy cycle. Saturn's eddy winds are more difficult to measure, the eddies themselves being harder to see. Scientists hope that Saturn will yield its secrets for *Voyager 2*, which has a more sensitive imaging system and is being programmed to make these important observations.

Besides making wind measurements *Voyager* also measured the atmospheric composition and total energy output of Saturn. Here another difference from Jupiter emerged, one that challenged scientists' understanding of the formation and evolution of these gas giants. Both Jupiter and Saturn radiate more power than they absorb as sunlight. The excesses come from the interiors of the planets, and theoretical models have been constructed to explain them. The models start with a hot ball of hydrogen, helium, and other elements in the appropriate abundance ratios. (To arrive at Saturn's present bulk density, one is constrained to start with mixtures that resemble the sun's.) Once the mass has cooled for 4.5 billion years—the solar system's age measured from radioactive decay in meteorites—the energy output in the model can be compared with the measured output. For Jupiter, the computed value agrees with observation. For Saturn, however, the computed value is too low.

Thus the planet generates more energy than can be accounted for by the simple cooling and contraction of a homogeneous mixture of solar composition. Another energy source is needed. Fortunately such a source exists and had been predicted before *Voyager*. Saturn, being less massive, is cooling faster than Jupiter, and today its interior is colder than Jupiter's. At some time, calculated to be about 2 billion years ago, Saturn's internal temperatures dropped below a critical point where helium condenses at the surface of the planet's fluid core of metallic hydrogen. As with a terrestrial air mass that is cooled below the saturation point, droplets form and then rain. These helium raindrops fall great distances inside Saturn and release heat by rubbing against the hydrogen fluid as they fall. Averaged over 2 billion years, the energy released if half the helium were to condense would just about explain the excess heat unaccounted for by simpler models. Because Jupiter cools more slowly, the critical point at which helium condenses is only now being reached in the interior of that planet.

Thus helium rain provides an extra energy source for Saturn but not for Jupiter, in agreement with the observed energy outputs of the two planets. Additional verification comes from the observed abundances of helium in the two atmospheres. *Voyager* measured 6 percent helium molecules on Saturn, 10 percent on Jupiter. The solar value would be 11 percent if the hydrogen were to combine into H_2, as on the giant planets. The lower helium abundance in Saturn's atmosphere implies a higher abundance in the core, as would be expected if helium rain had been falling for 2 billion years. The raindrops form about halfway to the center of the planet, where the pressure is millions of atmospheres. Yet the entire outer envelope loses its helium uniformly because it is stirred by convection. Therefore, the depletion of helium in Saturn's atmosphere reflects quite accurately the helium that has condensed at deeper levels throughout the history of the planet.

Finding this explanation for Saturn's extra internal heat is comforting to those who try to understand the solar system's formation and early history. It is axiomatic that the planets formed simultaneously 4.5 billion years ago. The initial composition of the material resembled that of the early sun, but was modified close to the sun by high temperatures. The gravitational energy of the formation event warmed all the planets, but only the most massive objects have retained this energy to the present day. Jupiter and Saturn now seem to fit this picture. It is not an improbable story. Similar events can be seen happening elsewhere in the galaxy today. The inference is that our solar system is not an unusual place. The conditions from which life evolved may have occurred on many of the billions of stars in our galaxy. □

Two of Saturn's large satellites, Tethys (above) and Dione, show up clearly against the blackness of space in this image made at a distance of eight million miles.

in the world that can do all of this?

Not a static African import, the art of the Maroons has a history of development in South America. The shoulder cape, below, worn by a man, was sewn using colors and a patchwork style popular earlier this century.

Antonia Graeber

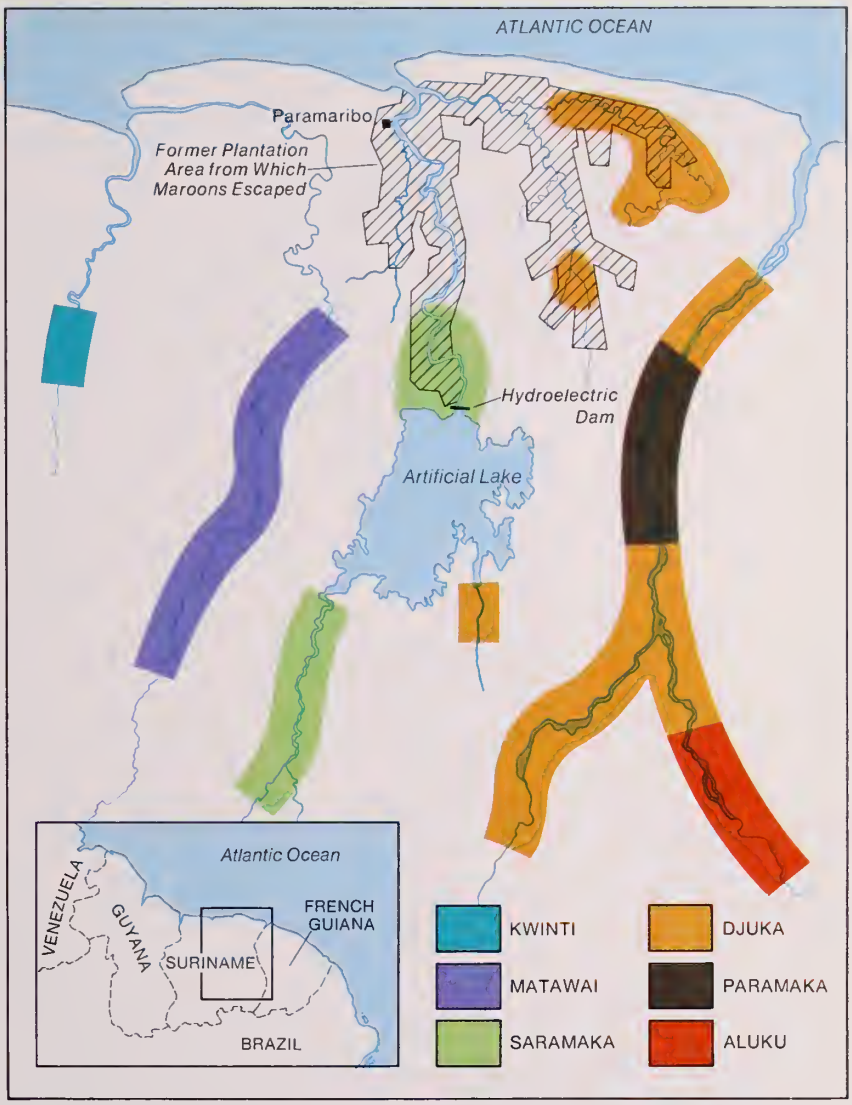
Art of the Rain Forest

Descended from escaped slaves, the Maroons of Suriname have drawn on their diverse African past and their unique New World experience to create a way of life rich in artistic expression

by Sally Price and Richard Price

Three women are sitting and working in an open-sided hut under a palm-leaf roof. Carefully patterned arrangements of scar tissue create sharp, raised accents on their bodies, and their skirts and waist ties make splashes of color against the earthen floor. Among them, they are producing designed manioc cakes, an elaborate hairdo, carved calabash bowls, and decorative calf bands, casually combining individual artistry, mutual cooperation, and lively aesthetic discussion.

The ancestors of these women were Africans sold into slavery in the Dutch colony of Suriname in South America. They escaped into the rain forest just north of Brazil, where they fought wars of liberation for 150 years. In the 1760s, a full century before the general emancipation of slaves in Suriname, these so-called Maroons (also known as Bush Negroes) won their freedom from the colonial government. By that time they had succeeded in building new societies and cultures that epitomize the remarkable resourcefulness of Africans and their descendants everywhere in the Americas. Today, there are six Maroon tribes in Suriname, speaking variants of two main languages. (The word *maroon* derives from the Spanish *cimarrón*, a word originally used to refer to domestic cattle that had taken to the hills in Hispaniola; by the early 1500s, however, it had come to designate the slaves who escaped from captivity in plantation colonies throughout the Americas.)



Even in the informal gathering of these three women, the pervasiveness of art in everyday Maroon life is unmistakable. One woman has brought a supply of manioc flour and set up a large round griddle over a barely smoldering fire. She is baking large, dry cakes, which in the coming days will be broken in pieces, dipped in water or broth, and eaten. The second woman sits on a handsomely carved stool with a clean, wet, hemispheric calabash shell on her lap and a collection of broken bottle pieces in a scrap of cloth on the ground. Next to her, the third woman sits on an old cloth on the earthen floor, her legs outstretched and a bottle on her lap; with a sharpened umbrella rib she is crocheting a pair of cotton calf bands for her husband, using the bottle as a form to create an evenly circular band.

The first woman spreads her manioc flour deftly over the dry griddle, draws her fingers over the entire surface to form decorative patterns, and carefully sifts a thin layer of flour over the top. While each cake bakes, she works on a hairdo for the woman with the calabash. Standing behind her seated friend, she sets up a network of parted sections and braids each section as part of an overall design. The braids around the face protrude forward and are secured with hairpins shaped out of scrap aluminum wire; those to the back are linked together; and a long, tightly braided line of hair runs between.

The woman with the calabash, well known in the village for her sense of design in this decorative art, is marking several designs as a favor to the woman sitting next to her, who will later finish

A special exhibition, Afro-American Arts from the Suriname Rain Forest, will appear at the American Museum of Natural History, October 28, 1981, to January 22, 1982. Organized by Sally Price and Richard Price, with the cooperation of the Museum of Cultural History of the University of California at Los Angeles and the support of the National Endowment for the Humanities, the exhibition presents the full range of Maroon arts in the context of this people's African heritage and their life and history in the New World.

The Maroons live along rivers in central and eastern Suriname. The Djuka, Aluku, and Paramaka tribes speak variants of one language, while the Saramaka, Matawai, and Kwinti speak variants of another.

executing the bowl carving herself. As she works, she constantly rotates the prepared shell between her hands, trying to remember the details of a particular design she is trying to reproduce, and adjusting the position of the calabash so that she can cut each curved line. She discusses with the woman sitting at her side the design they want to replicate, and finally, when neither can recapture just how its appendages were curved, settles on a new version, which she later decides is even better than the first.

The third woman, working steadily around the calf band, enlists the advice of her friends concerning the width of the red and yellow stripes that form its center. As the three of them work, their conversation alternates between village gossip and discussion of their artistry.

We see in this gathering the influence of aesthetic considerations in all areas of Maroon life, from food preparation and meal service to clothing and grooming. We see the active participation of Maroons in a wide range of artistic media. And we see the Maroons' enjoyment of discussions focused on artistry and aesthetic evaluation. As the anthropologist Melville Herskovits noted fifty years ago, "Bush Negro art in all its ramifications is, in the final analysis, Bush Negro life."

Both graphic and performing arts have been elaborately developed by the Suriname Maroons. Visual media include woodcarving and painting, different techniques of calabash carving, designs baked into manioc cakes, colorful textiles made from narrow strips of commercial cloth, embroidery of many kinds, appliqué, decorative scarring of the body (cicatrization), hairdos, the carving of designs on imported metal spoons, and the manufacture of carved aluminum combs, decorative beadwork, colorful yarn tassels, crocheted calf bands, and a kind of knitted multicolor ribbon.

The performing arts play an equally extensive role in village life. Specialized dances are performed by mediums believed to be susceptible to possession by various gods, and there are many secular dances, each enjoyed in a particular social context. Distinctive song styles are used in the whole range of Maroon ritual events, from complex funerary rites to the domestication of a new god believed to possess people, as well as in communal labor such as felling trees or hauling logs, and in many casual or even solitary settings. It is rare to walk through a Maroon village without hearing someone singing. Drums are used singly or in various combinations to accompany different secular dance forms; to announce, supervise, and comment on the proceedings of large public council meetings; and to communicate with each kind of possession god, with other deities and spirits, and with the ancestors. And there are other musical instruments as well—bells and wooden trumpets, a stringed instrument made with a gourd, and a "finger piano." Finally, the verbal arts—folk tales, play languages, proverbs, oratory, speeches made by possessed mediums, and prayer—exhibit a wide range of stylistic modes in the tribal languages and keep alive a large number of distinctive esoteric languages that are used only in special ritual settings.

The breadth of Suriname Maroon art extends considerably beyond the wide variety of formal arts. Even manufactured items imported from China, Japan, the Netherlands, the United States, and elsewhere—including guns,

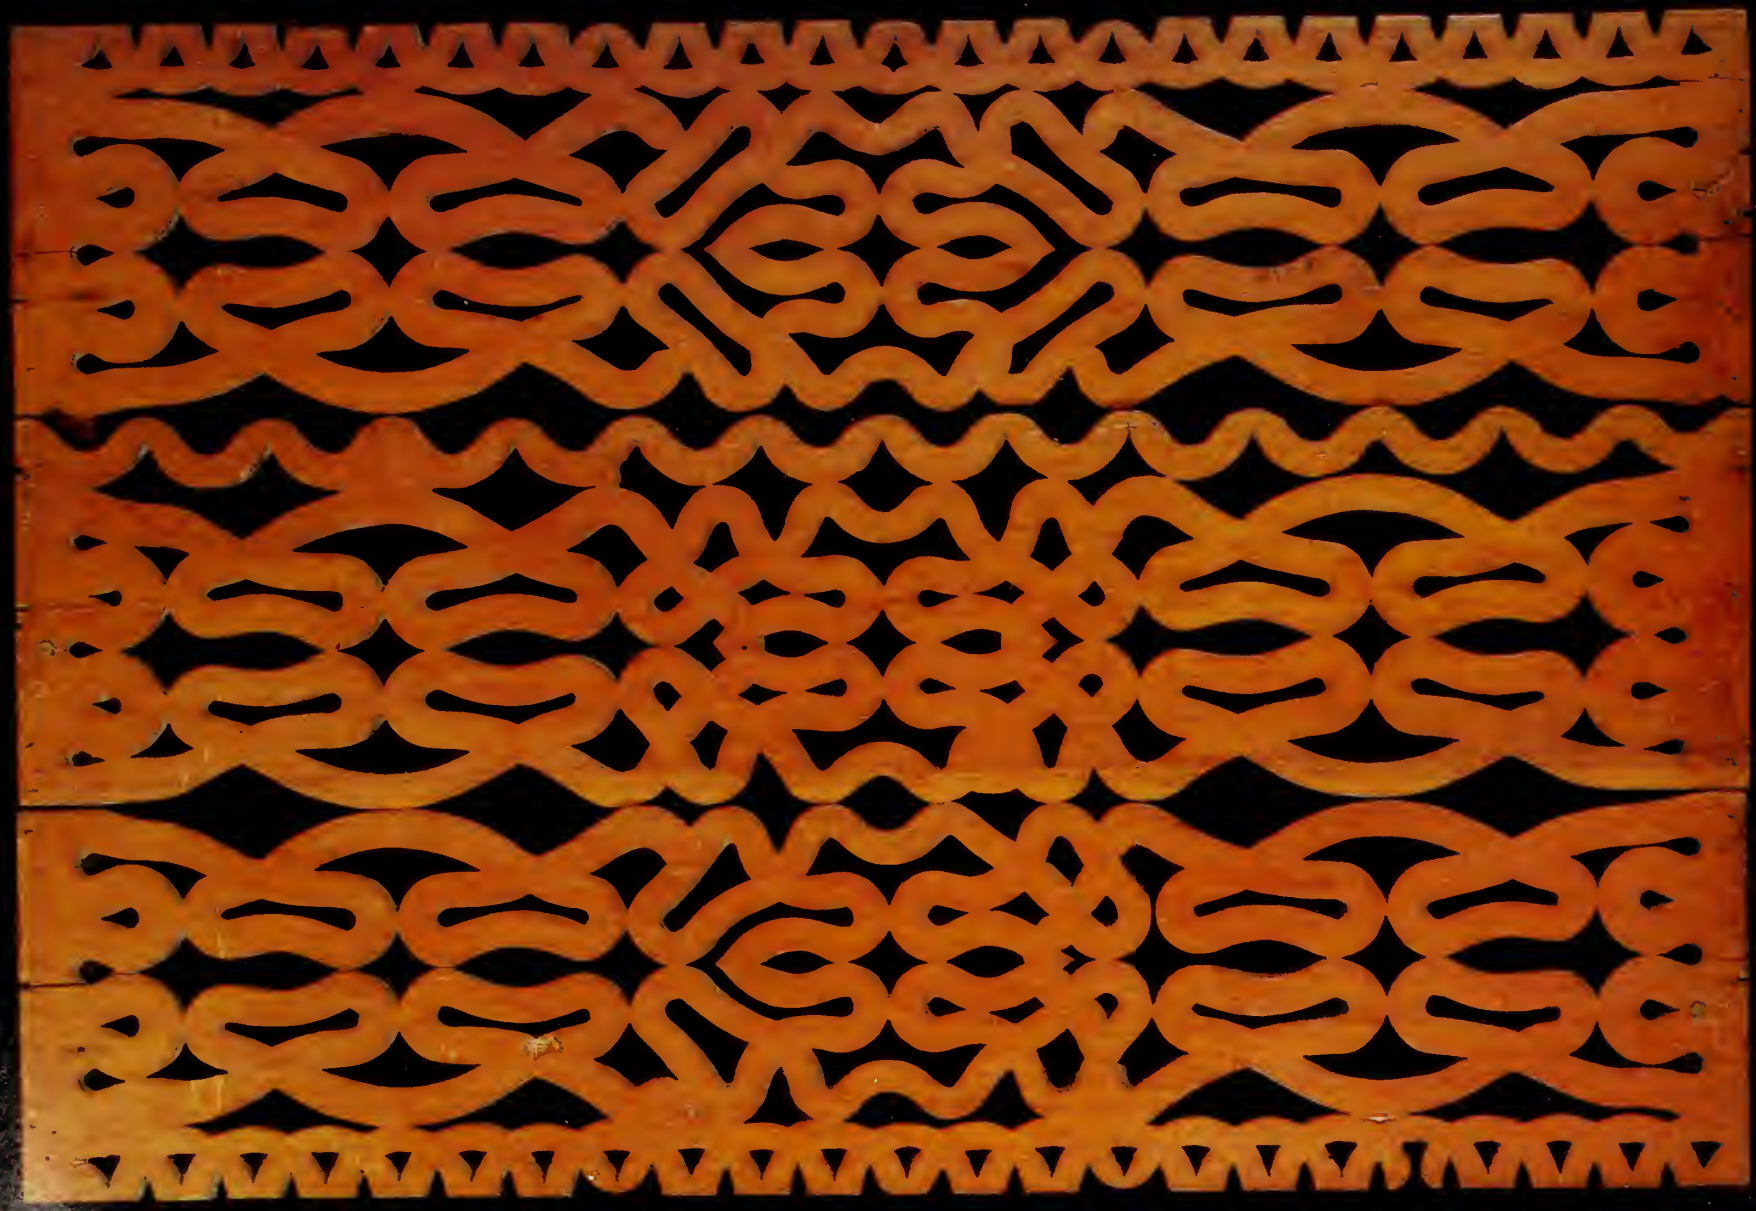
An engraving by William Blake for an eighteenth-century narrative by John Stedman depicts a slave guiding troops in pursuit of escaped slaves. The Maroons eventually won their freedom from the Dutch colonists.

Richard Price

Richard Price

Another of Blake's engravings in Stedman's narrative depicts the whipping of a female slave. Stedman, a soldier who fought rebel slaves, wrote sensitively about slaves, their masters, and the Maroons.

buckets, trade cotton, bottles, lanterns, and so on—have formed a substantial contribution to the aesthetic life of Suriname Maroon societies since the very earliest days of their formation. The men who buy these objects at the end of lengthy stints as wage laborers outside the tribal territories (in coastal Suriname, French Guiana, and elsewhere) select their purchases very carefully. In addition to basic utilitarian features, the different perfumes of soaps, the slightly varying finishes and proportions of tin lanterns, the colors of different cloths, the fringed edgings on cotton hammocks, and the curve of the handles on aluminum pots are all subjected to scrutiny. Once brought back to the home villages and distributed to wives and kinsmen, the chosen articles undergo the same kind of exacting evaluation. The most successful purchases are displayed with pride, serve as the inspiration for popular songs, and are understood to reflect the care and aesthetic sense of the man who bought them. Many of these objects are then further embellished in the villages; for example, metal spoons from French Guiana may be elaborately incised with designs found also in local woodcarvings, and pots are often marked with simple carvings or decorated with red tape.



Besides their variety, the arts of the Suriname Maroons are unusual in the extent to which they have traditionally been practiced by the entire population. For example, all men carve a wide range of objects as gifts for women—from canoes and house fronts to combs and food stirrers—and all women produce elaborate patchwork and embroidered textiles to be worn by men. This is in decided contrast to many African societies, where only certain individuals are trained to be artists, producing and selling sculptures, carvings, and woven textiles. (In some African societies the role of critic is also a recognized specialization.) Suriname Maroons, however, expect *all* adults to be active artists and assertive critics.

Children are fitted into this world of artistic production, performance, and connoisseurship from a very early age. Regardless of individual temperament, they all need the skills and aesthetic framework that will enable them to participate fully in Maroon life. From the time children can stand, they are frequently and enthusiastically encouraged to dance to the rhythm of hand-clapping or thigh slapping. Six-year-old girls begin to learn the principles of narrow-strip textile composition by fashioning three-piece aprons out of scraps of cloth too small for other uses, and boys carve crude wooden objects, such as combs and small paddles, at an equally early age.

A significant aspect of Maroon artistry is the central role it plays in social institutions. In discussing art with us, Maroons very often made reference to the social uses of the objects—most frequently enumerating the decorated objects that would be presented in particular situations, such as the rites for newborns and adolescents, funeral ceremonies, and the celebration of a man's return from an extended trip to coastal Suriname. People rarely discussed particular woodcarvings without referring not only to the artist but also to the woman for whom the woodcarving was made and the details of the couple's relationship at the moment each piece was given. Just as dance,

This interior openwork door was carved by a Saramaka man about 1930. Maroon architectural decoration includes carving, painting, and wood inlays. Often, the entire façade of a house becomes a work of art.

Antonia Graeber

Maroon men carve calabashes only on the outside, using knives and chisels to create a textured design. Calabashes made by women are decorated on the inside with free-form shapes carved with pieces of broken glass.

song, and drumming are conceptualized in terms of the social events for which they are most frequently performed, the meaning of artistically designed objects are bound up with the social moments for which they are intended.

Together with fish and game, garden and forest products, and Western imports, artistic objects contribute to the fulfillment of a variety of social relationships, from voluntary formal friendships to ties of kinship and marriage. Most important among these are the relationships between a man and his wives. Woodcarving, calabash carving, textile arts, and decorative body cicatrization are generally intended to serve in the ongoing campaign of every adult to attract spouses and lovers and to maintain their affection over time.

A husband's return from the coast is one of the many regular contexts in which gifts, including artwork, are presented and reciprocated. A Maroon woman provides the following description of this custom, in which a man's sisters serve as intermediaries, presenting the gifts he has brought back to his wife—salt, kerosene, kitchenwares, and other imported goods. After the trunks holding the gifts have been opened,

> everyone really celebrates in that house! Then the woman says "Listen to me!" and she jumps up. She'll load an enamel basin with some calf bands. She'll load up some narrow-strip textiles. She'll put in some cross-stitch embroidery. She tells her sisters-in-law, "Take these to the man for me." And they'll set everything on their heads and carry it off to the man. The woman will stay in her own house, rejoicing over the presents, while all the others go off to the man's house. Then the man will say, "Well, here's something for you to take over to the woman." This last present can be anything that he's brought back from the coast—any kind of dishware, maybe an aluminum water jug. . . . They bring it over and say, "Woman, don't you see? Here's something that your husband sent over for you." The wife will jump right up. She'll grab the one thing that she hasn't yet given him and, right there, she'll give it to her husband's kinswomen. She'll always have one thing held back, to give him separately. It could be some cross-stitch or an embroidered neckerchief, or whatever. "Take this thing here. Go drape the man with it for me." After her gift is presented, shouts will ring out *wooooooo*. . . . "My goodness! The woman has really pulled the goods to the ground!" That means that she hasn't been shamed by having made too little to reciprocate his gifts properly. That's what's known as "pulling the goods to the ground."

Many visitors to Suriname have envisioned Maroon arts less in the context of their contemporary setting than in the context of their African roots. The villages of the rain forest have often been seen as a "little Africa in America" and Maroon arts as direct "African survivals." The title of an article on Maroons that appeared in the pages of this magazine more than forty years ago was quite explicit: "Africa's Lost Tribes in South America: An On-the-Spot Account of Blood-chilling African Rites of 200 Years Ago Preserved Intact in the Jungles of South America by a Tribe of Runaway Slaves." And more recent visitors have even claimed that Maroons have maintained a society "that is 'more African' than much of Africa is today." Behind this view lies the myth that so-called primitive societies exist outside of history, that they are by nature strongly resistant to change, and that they develop only when other, "more advanced" societies impinge upon them.

In fact, societies differ enormously in their attitudes toward change and in the extent to which they exhibit an internal cultural dynamism. The societies of the Suriname Maroons, like the vast majority of societies in pre-twentieth-century West and Central Africa, have *always* been highly dynamic. Our fifteen years of research on Maroons—in historical archives, museums, and Maroon villages—has persuaded us that creativity, innovation, and artistic development from one generation to the next lie at the very heart of their cultural life. Far from being static leftovers from seventeenth-century Africa, Maroon societies have continually developed as their members played and experimented with the artistic heritages of their ancestors, adapting them creatively to their changing lives.

We now know that the original Maroons produced little decorative woodcarving or textiles; their clothing was extremely simple and their houses and furnishings largely unembellished. It was only over time that the relatively crude woodcarving of the mid-nineteenth century developed into the twentieth-century art that has struck many outsiders as "African looking." And the multichromatic Maroon narrow-strip textiles that so closely resemble

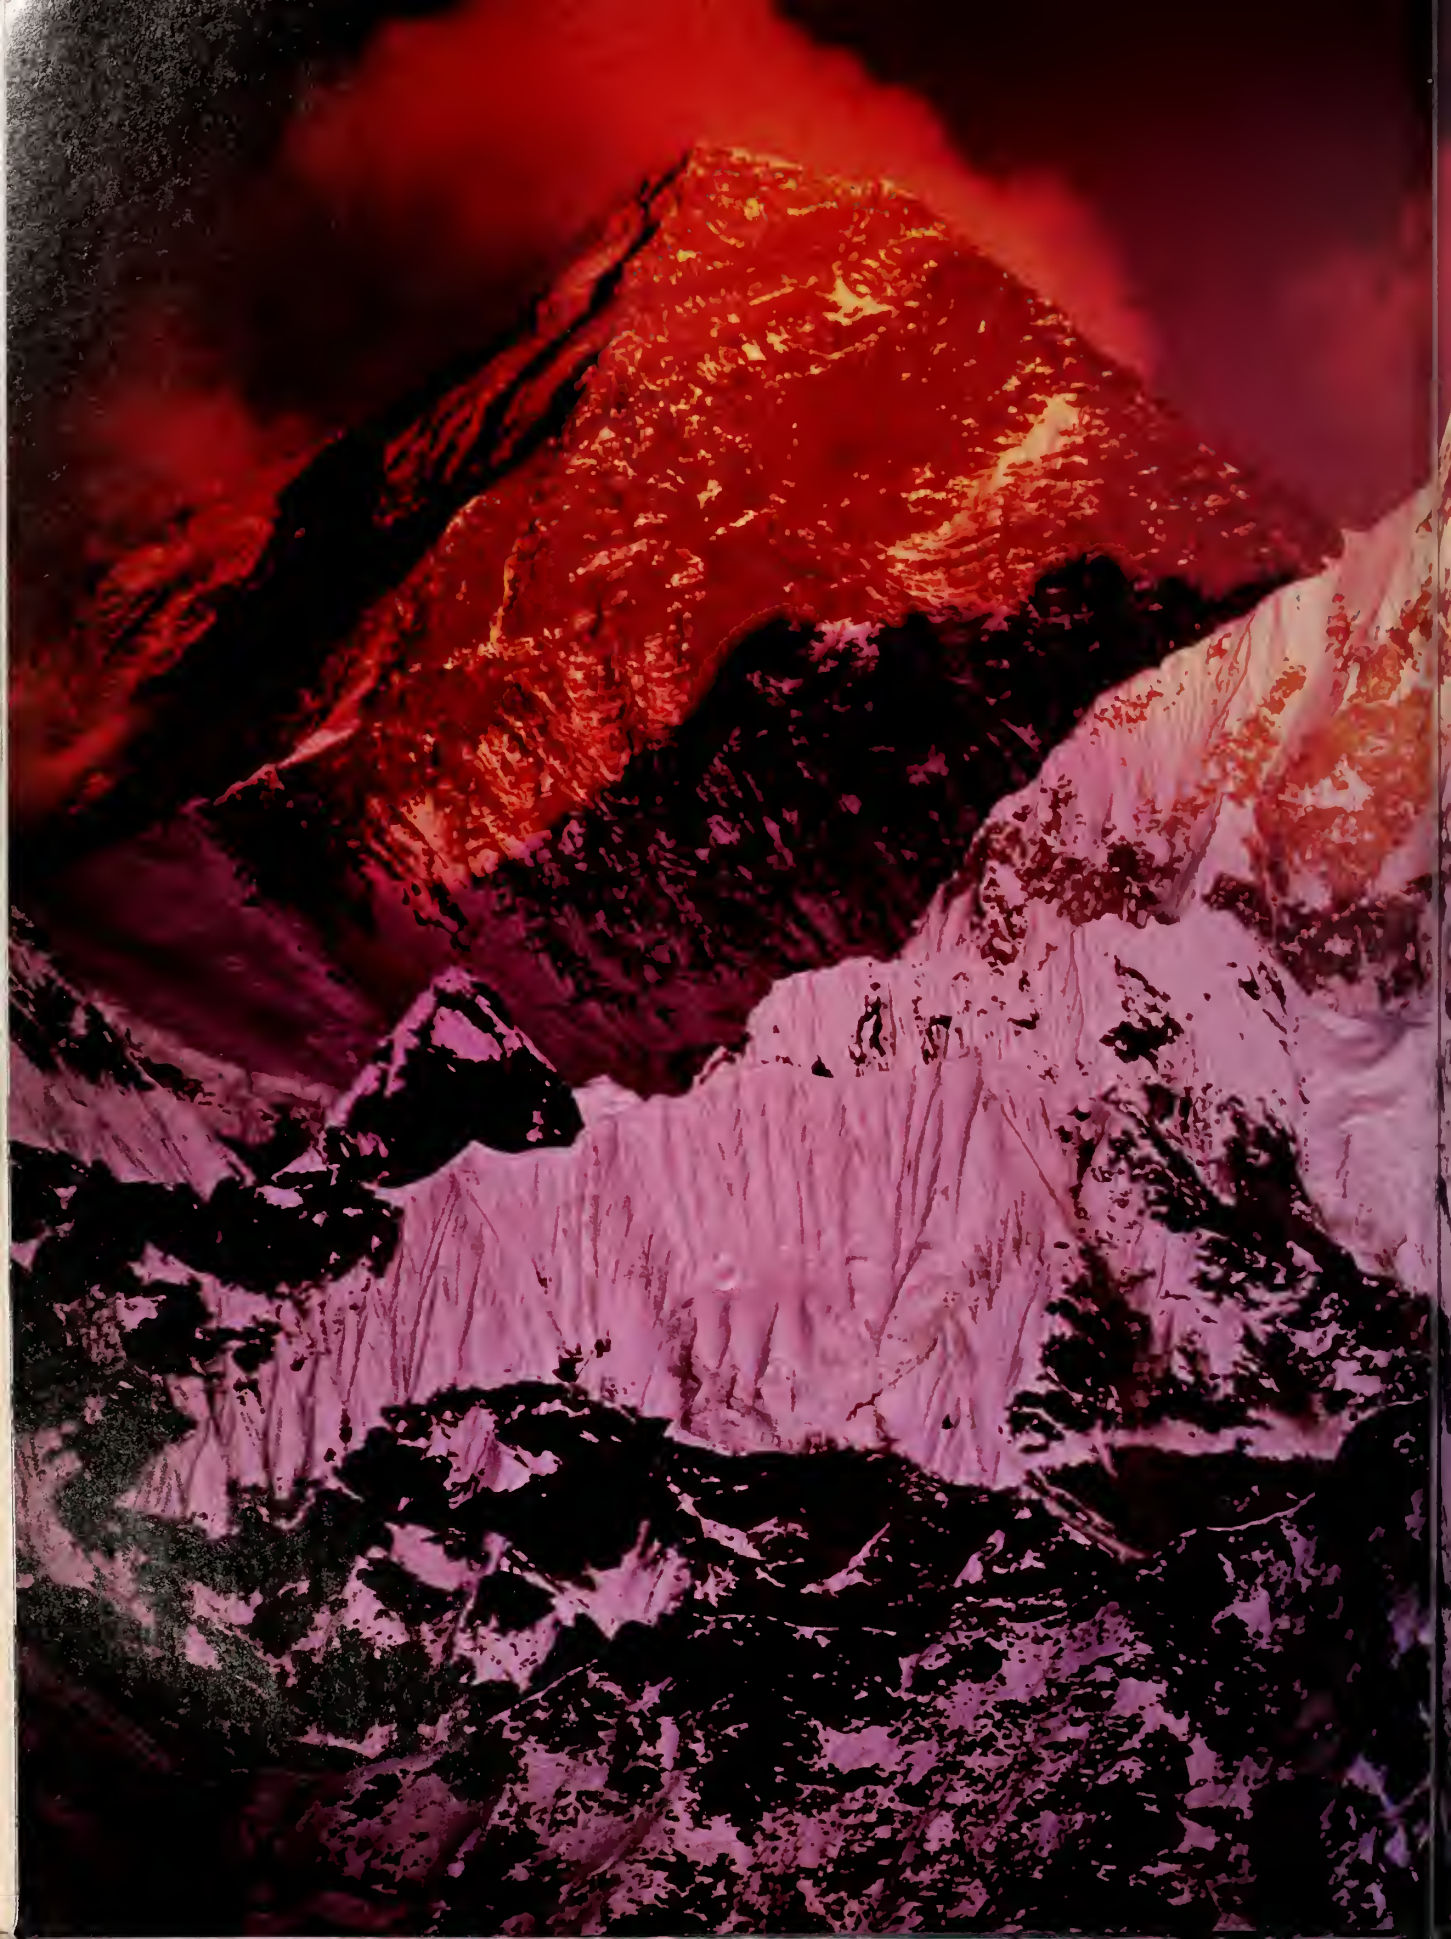
Michael K. Nichols

The pots and pans in a Saramaka woman's house are kept proudly on display. Obtained by men who travel to coastal areas to work for wages, such imported items are selected with a critical eye.

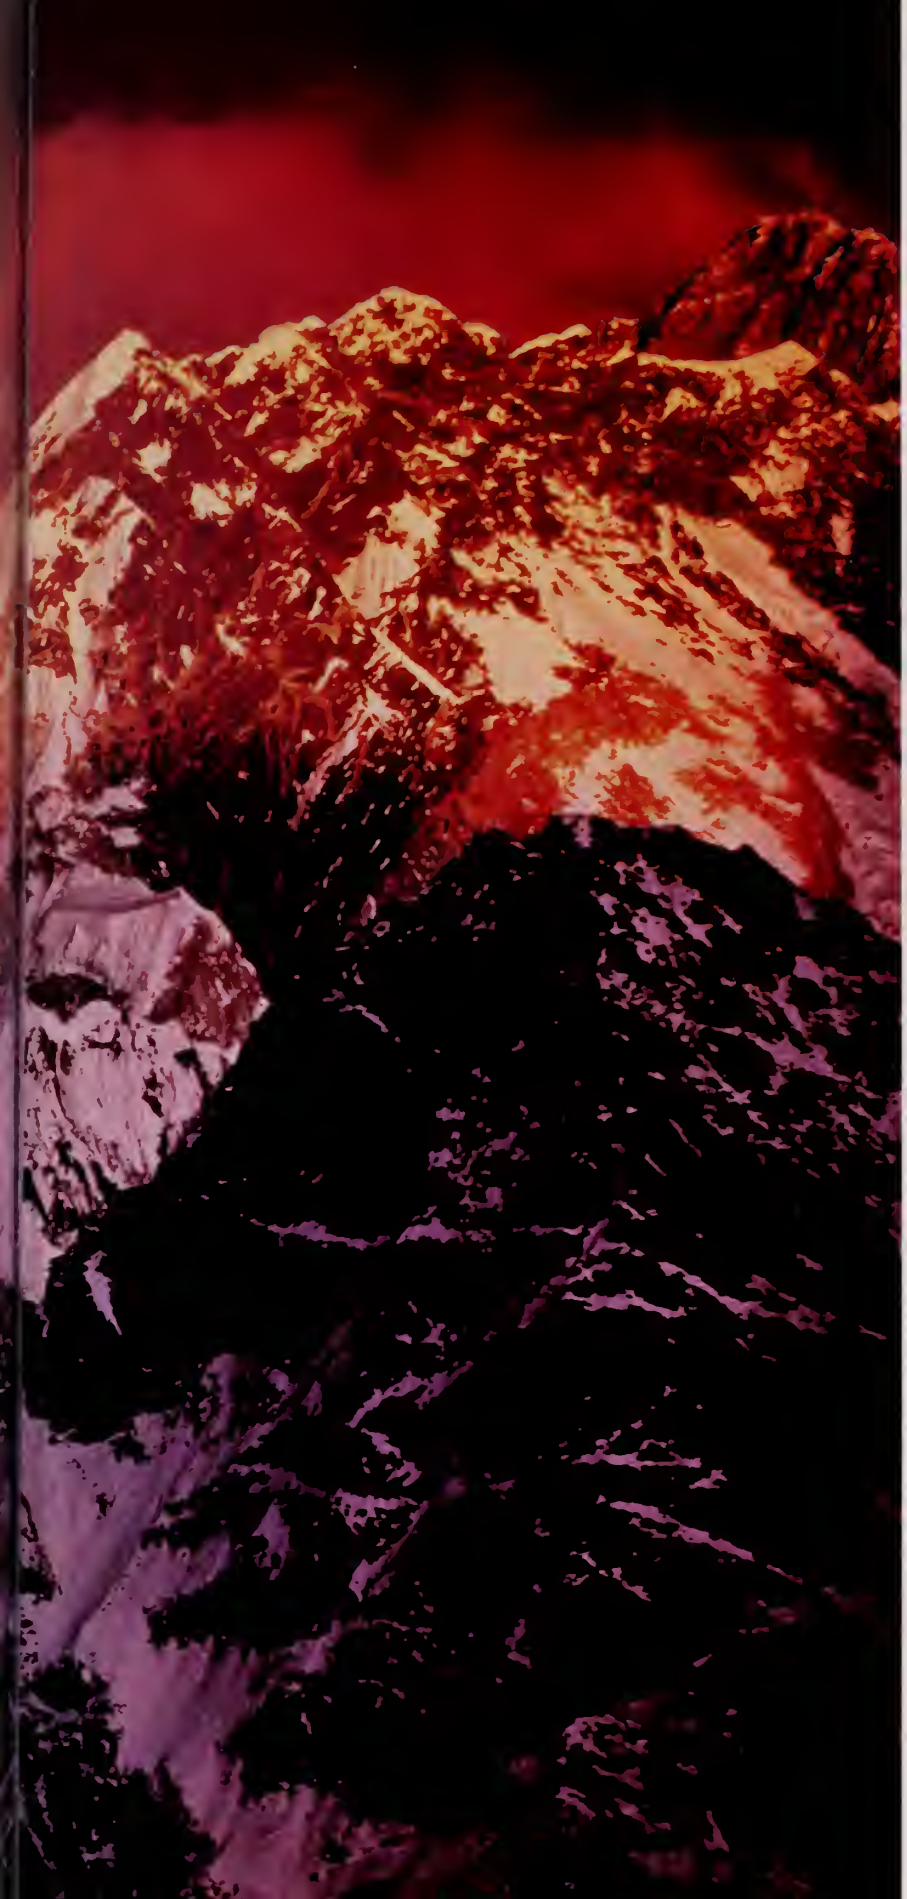
Richard Price

Enjoying a snack of oranges, two Saramaka boys turn the peels into fanciful face masks. Children are drawn into the world of artistic production, performance, and connoisseurship at an early age.

West African *kente* cloth became popular only during the present century, as a replacement for a very different textile art of embroidered designs that earlier Maroons executed in red, white, and either black or navy. Paints, introduced in a few conservative colors less than 100 years ago, have since come to play a central role in the arts of the eastern Maroons. And calabashes, which until the mid-nineteenth century were decorated only on the outside surfaces by men, began to be carved on the insides by women in an entirely new decorative style executed with bits of broken glass.



In light of this history of development and change, one of the main puzzles in the study of Maroon art is how to explain visible resemblances between the arts of the Maroons and those of West and Central Africa. Given the stylistic developments that have repeatedly led Maroon arts in new directions, how has the cultural legacy of Africa been expressed over the centuries? The answer lies more in the continuity of aesthetic ideas than in the direct transmission of African forms from one generation to the next. The present-day Maroons are the descendants of people who were separated from family and friends, stripped of personal possessions, overworked, and tortured. The first Maroons were challenged to form new ways of life in an unfamiliar environment and in cooperation with other Africans who spoke languages different from their own. The survival of their communities is, in itself, evidence of their remarkable inner resources. And the rich traditions of music, dance, folklore, and the visual arts that have evolved in their lives reflect the special strength of their aesthetic and spiritual sensitivities and interests. The Maroons were not in a position to continue such African traditions as sculpture, carving in ivory, and weaving. But they did succeed in carrying on many of the fundamental ideas that had contributed to the character and meaning of those arts in Africa—ideas about symmetry, color contrast, and syncopation, and above all, the understanding that art has a place in all aspects of daily life.



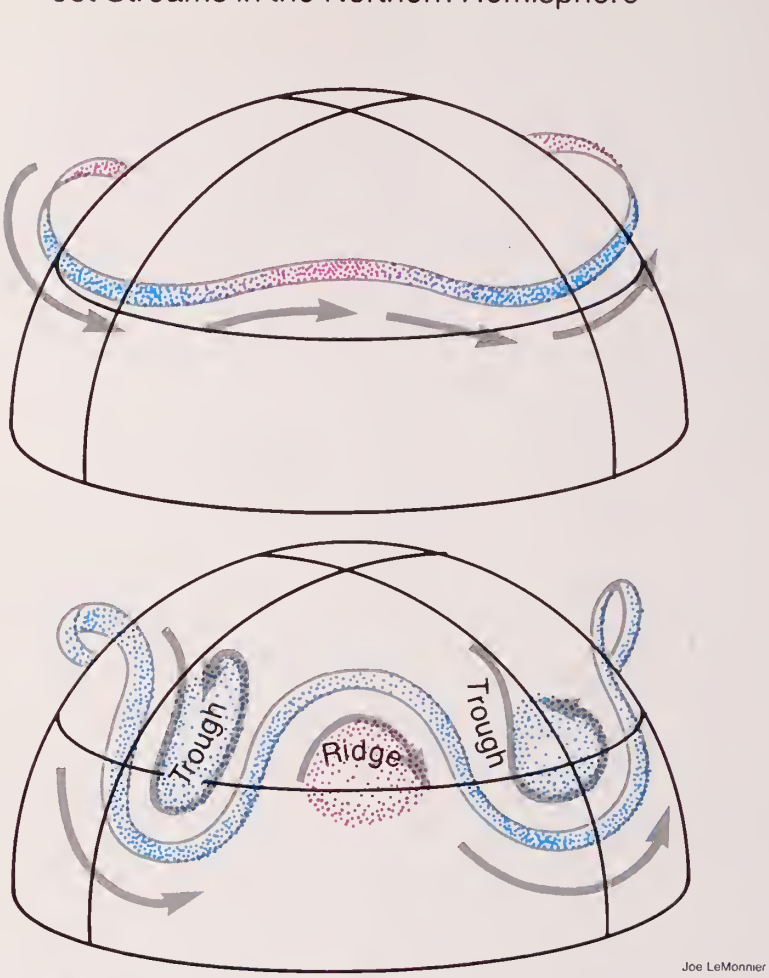
Even under the harshly repressive conditions of slavery in Suriname and during the century-long period of guerrilla warfare against the Dutch colonists, these people still made use of opportunities for storytelling, dancing, drumming, and singing. They made choices about the way they walked, carried their babies, and wore their hair. They expressed preferences in the arrangement of their house furnishings, the mending of their clothes, the serving of their meals, the layout of their gardens, and countless other aspects of daily life that did not require the specific resources of more formally elaborated artistic media. In this way, aesthetic ideas were passed on and applied inventively to the changing artistic materials of each generation. Forged in an inhospitable rain forest by people under constant threat of annihilation, the arts of the Suriname Maroons stand as enduring testimony to Afro-American resilience and creativity. They reflect the remarkable exuberance of the Maroon artistic imagination, expressing itself within the rich and broad framework of African cultural ideas. □

Carved between 1915 and 1920, this Saramaka stool was embellished with brass tacks, a popular ornamentation at the time. Woodcarving, the most widely acclaimed Maroon art, is practiced by all the men.

Antonia Graeber

The Tibet Connection

Having discovered some new details of far-flung climatic linkages, meteorologists are reexamining historic weather maps and revising their computer models



by Elmar R. Reiter

Weather may seem to be just a local affair, but in fact, its events are not self-contained. Rather, each is part of a highly complex global system involving such variables as temperature, air pressure, wind, humidity, and precipitation. The bonds that join these atmospheric conditions are the jet streams—large, high-speed air currents that circle the earth in ever changing patterns at altitudes of five to thirty miles. Jet streams in the troposphere (the innermost layer of the atmosphere, extending up to about ten miles) travel at velocities of between 60 and 400 miles per hour, moving blizzards, rainstorms, and squall lines, and dragging lower-lying air packages across the face of the land, thereby affecting local weather conditions. Over North America the jet streams usually shift northward into Canada during the summer and migrate as far south as the Gulf of Mexico during the winter, but their behavior is not always easy to predict.

Erratic meanders in jet stream systems are closely related to some of the

Mount Everest, at the left, the world's highest peak, is on the Tibet-Nepal border. Rising 29,028 feet, it is part of the Himalayas. To the right is Lhotse, 27,923 feet high. Sheltered behind the 1,500-mile-long curving Himalayan range is the Tibet plateau. Because the Himalayas do not lie at right angles to the airflow in the upper troposphere, jet streams can circle around them.

Yoshikazu Shirakawa/Image Bank

The normal jet stream pattern, upper drawing, differs from the strong wavy pattern, lower drawing, that correlates with regional temperature anomalies. Ridges tend to have warmer than normal temperatures (red), while troughs of the jet stream match regions of cold temperature anomalies (blue).

recent weather anomalies in the United States. For example, during the winter of 1980–81, the jet streams, instead of moving south, remained along or to the north of the Canadian border in the Rocky Mountain region; to the east, they strayed over the New England region. That brought to Colorado and neighboring states a lack of snow, severe drought conditions, an abundance of sunshine, and unseasonably warm weather, while the northeastern seaboard states were swept by arctic air masses and snowstorms. This situation was nearly reversed in the winter of 1979–80, when New York State's Lake Placid, scene of the Winter Olympics, was starved of snow but record amounts fell in the Rocky Mountains under that winter's main jet stream flow.

The changeable behavior of the jet streams from one year to the next is not confined to the United States. Wayward shifts of the jet streams have also been associated with crop failures in the USSR and droughts in China during the past four to five years. These events raise the question of what causes jet stream aberrations.

Despite the great altitudes at which they circulate, jet streams are themselves affected by terrestrial features, such as mountain ranges and high landmasses, and by such variables as changes in land- and sea-surface temperatures. In the Northern Hemisphere the principal geographical features ultimately responsible for jet stream meanders are the Rocky Mountains, the Himalayas, and the Tibet plateau in Southeast Asia.

Global atmospheric airflow at midlatitudes in and below the jet streams has a west-to-east orientation. The Rocky Mountain chain, whose highest peak is 20,320-foot Mount McKinley in the Alaska Range, extends some 3,000 miles from northwest Alaska southward to central New Mexico. The Rockies lie almost exactly perpendicular to the airflow pattern, presenting a formidable barrier. Because the mountains are so extensive, the air cannot easily move around them, and so it goes over them. The Tibet plateau, however, is a different kind of obstacle. On the south, the plateau is sheltered by the Himalayas, which extend in a broad curve some 1,500 miles and include peaks that rise more than 25,000 feet; on the north it is sheltered by the similarly long Tien Shan mountain chain, with peaks exceeding 20,000 feet. The average elevation of the plateau itself is more than 14,750 feet.

Regardless of its name, the Tibet plateau is not an expanse of level land but a corrugated area of mountains and valleys, containing the headwaters of several large rivers and many saltwater and freshwater lakes. The minimum elevation of the valleys is 12,000 feet. Despite the enormous height of the Himalayas and of the plateau itself, these barriers, unlike the Rockies, do not lie perpendicular to the airflow pattern nor are they insuperably extensive. Air can therefore flow around them. But this deflection of airflow gives rise, in turn, to large meanders in the global jet streams. And these meanders set the stage for the "Tibet connection" with weather and climate in the Northern Hemisphere, a phenomenon of far-reaching implications that can affect Indian monsoons, cause North American summer heat waves, and that may be linked to the unusually cold North American winters of 1976 through 1979. That such a linkage exists is evident from weather maps.

If daily tabulations of global atmospheric airflow and pressure distributions for any month in any year are averaged, the "wiggles" associated with traveling waves in the airflow and perturbations that cause the daily variability of local weather disappear. What is left is the stable wave pattern caused primarily by the topography of the earth's surface. In regions without significant mountains, that is, over the Atlantic and Pacific oceans and over Europe, the observed mean monthly flow patterns are probably due to resonance in the effects of the two aforementioned major mountain obstacles.

If the physical barriers of mountain ranges and a high plateau were the only factors acting on atmospheric airflow,

Elmar R. Reiter

Shepherds tend their flocks on the treeless, almost barren plateau. In the background are the Transhimalaya Mountains of central Tibet.

seasonal variations in weather patterns would follow the same course year after year. But recent climate anomalies show that this is not the case. Obviously, other factors must be involved in generating large meanders in the jet stream flow. The prime candidate in effecting these changes is the process that supplies the upper atmosphere with heat energy from below.

When the air layers on their eastward flow rise over the Rocky Mountains, they are squeezed vertically by the stable stratosphere above them and are curved anticyclonically, that is, in a clockwise direction. This establishes a high-pressure, warm-air system over the Rockies and the Great Basin. In the lee of the Rockies, the warm air expands, creating a low-pressure cyclonic, or counterclockwise, system containing cooler air masses. Jet streams are affected by the horizontal contrast of temperature and pressure below them. Therefore, this combination of anticyclonic and cyclonic airflow in the lower atmosphere alters the path followed by the high-traveling jet streams.

In the case of the Tibet plateau, temperature again seems to be the controlling variable. The plateau is colder in winter and warmer in summer than the "free" atmosphere at the same elevation above sea level over the adjacent land areas and oceans. A cold Tibetan plateau is frequently invaded and dominated by cold, low-pressure systems that are associated with cyclonic, or counterclockwise, airflow. The juxtaposition of cold air over Tibet and warmer air over India, to the southwest, represents a horizontal temperature contrast between the two regions and results in horizontal pressure contrast, with low pressure over Tibet and high pressure over India. This pressure differential tends to be at a maximum near the tropopause level of the atmosphere (at approximately 30,000 to 40,000 feet), where a strong jet stream skirts the Himalayas.

A law of physics dictates that in the Northern Hemisphere, when the wind is at your back, low pressures with cold air must be to your left and high pressures with warm air to your right. (This rule, derived originally from observations of low-level airflow, also applies to the jet streams.) Accordingly, the streams flowing around the Tibet plateau in winter move in a west-to-east direction. But when the sun starts to heat the plateau in spring, and the air over Tibet becomes warmer than the air at the same altitude over India, the plateau ceases to serve as a "refrigerator," causing a cyclonic curvature of the jet stream, and begins to act like a giant, elevated "hot plate."

During the spring and summer, heat from the land rises and is mixed into the turbulent planetary boundary layer of the atmosphere. (This layer is the part of the atmosphere, about three-quarters of a mile thick, on the average, that lies immediately above the earth's surface.) The layer tends to be thicker over warm surfaces than over cold ones. Hence a warm region acts on the flow of the lower atmosphere in much the same way that a wide mountain range acts on the jet streams, causing the airflow to skirt anticyclonically—in a clockwise-curving arc.

As the heating of the high Tibetan landmass continues, the horizontal

In wintertime, cold air settles over the Tibet plateau, causing the formation of a low-pressure system with a cyclonic, or counterclockwise, airflow in the upper atmosphere at altitudes of about 30,000 feet. The effect is especially pronounced when there is prolonged and heavy snow cover on the plateau. South of the Himalayas, a west- to east-flowing jet stream is established and dry winter weather prevails over India and Southeast Asia.

Joe LeMonnier

temperature and pressure differences between Tibet and India are reversed from what they were in winter. In accordance with the above-stated law, an anticyclonic curvature is introduced into the prevailing jet stream, causing it to flow from east to west over the southern slopes of the Himalayas. This change in flow takes place in spring, and the jet stream reverts to its winter pattern in fall, the two reversals coinciding with the start of summer and winter monsoon seasons, respectively, in India.

Anomalies in ocean temperatures cause airflow phenomena similar to those seen on land and can also lead to the same kinds of feedback mechanisms in weather patterns. A number of scientists have noted that large areas of warmer than normal sea-surface temperatures in the North Pacific and North Atlantic tend to coincide either with persistent or recurrent high-pressure patterns in the atmosphere over these regions. On the other hand, large cold-water anomalies in the North Pacific and North Atlantic have been found to be associated with low-pressure systems in the atmosphere.

Low-pressure regions are associated with stormy and cloudy weather, whereas high-pressure regions usually have fair and relatively calm weather. In stormy weather, the ocean is stirred up by high waves, and cooler water from below rises to the surface, thus perpetuating below-normal sea-surface temperatures that, in turn, attract more stormy weather. A big low-pressure region over the North Pacific during January 1977, for instance, coincided with a large cold-water anomaly. The tendency for prevalent high-pressure patterns to develop over warm water diminishes the turbulent mixing of ocean water. Cold water, which is heavier than warm water, rises only when forced to by the wind. Thus high-pressure patterns keep the sea-surface layers relatively warm. Sunshine under relatively cloudless skies also contributes its share to keeping the ocean warmer than normal.

The thermal effects just described are usually of much smaller amplitudes than the deflection of airflow around Tibet and over the Rocky Mountains. Nevertheless, the jet stream wave patterns that are mainly set up by the Rocky Mountains and the Tibet plateau do seem to be affected by sea-surface temperatures. For example, in the eastern United States the cold winters of 1976–77 and 1977–78 occurred when the surface waters of the central North Pacific were abnormally cold but the surface waters off the west coast of the United States were warmer than usual. With this temperature distribution, the central North Pacific was characterized by stormy, low-pressure weather and a stronger than normal ridge—an extended high-pressure system—settled over the west coast regions of the United States and Canada, including the Rocky Mountains. The eastern side of this strong, persistent ridge served as an effective conveyor belt, ferrying cold arctic air into the central and eastern United States.

The 1980 summer heat wave in the south-central United States was marked by a persistent anticyclone in the same area. Meteorologists suspect that this phenomenon was triggered by the Rocky Mountains (which the jet stream tends to cross with an anticyclonic curvature). The anticyclone's persistence was most likely caused by the combined effects of an unchanging pattern of large-scale airflow waves between Tibet and the Rockies, surface temperatures over the Pacific, and feedback from the heat wave itself. The dry and hot soil of the south-central United States acted on the atmosphere as a giant furnace, heating up the lower troposphere and thereby extending the deflecting effects of the Rockies on the tropospheric airflow patterns farther to the east and southeast than is normally the case.

Snow cover can also bring about feedback that can cause certain weather patterns to become either persistent or repetitive, resulting in large seasonal anomalies. An example of such a feedback effect is the extended low-pressure region, or trough, that often settles over the central United States downwind of the Rocky Mountains. Such troughs create ideal conditions for the development of winter blizzards over eastern Colorado. These storms ordinarily move in a northeasterly direction, blanketing the country with several inches of snow. The snow blanket reflects the sun's radiation back to space, keeping the underlying soil from warming up. As a consequence, cold air moving down from Canada remains cold for extended periods and can cause repeated blizzards. Thus an extensive snow blanket reinforces the trough originally produced by the barrier effect of the Rocky Mountains. These combined effects contribute to lengthy periods of below-normal temperatures.

Snow cover in Tibet also comes into play. Normally, Tibetan winters are dry, resembling winters in the central Rocky Mountains. The average annual

Joe LeMonnier

As the Tibet plateau heats up during spring and summer, it warms the air, giving rise to a high-pressure system with anticyclonic, or clockwise, circulation in the upper troposphere. South of the Himalayas, this serves to establish an east- to west-flowing jet stream, bringing summer monsoon rains to India and Southeast Asia.

precipitation over wide areas of Tibet is less than sixteen inches and comes down mainly in the form of summer showers. Nevertheless, extensive winter storms occasionally bury most of the Tibet plateau under a lasting blanket of snow, and these snowfalls can have a significant effect on precipitation in India.

In April the plateau usually starts to act as an elevated heat source for the atmosphere, helping to generate a high-pressure system in the upper troposphere over Tibet. This system becomes the dominant feature of the Tibetan summer, and its strength, to a large extent, controls the Indian summer monsoon. The barrier and thermal effects of the Tibet plateau work together to produce the rain that hundreds of millions of people on the Indian subcontinent and in southeastern China rely on to sustain their crops. The sequence of weather patterns in that part of the world tends to go awry, however, when winter snows in Tibet are unusually deep and consequently resist the melting warmth of the sun.

The dazzling white of the snow surface reflects the sunlight and slows the warming of the soil. Under such conditions the Tibet plateau becomes a sputtering, ineffective "hot plate" over which the atmosphere's monsoon-sustaining anticyclone can build only with difficulty. If this Tibetan high-pressure, anticyclone system is weak and is established late in the season, the drenching rains of the Indian summer monsoon will also be late, and the rainy Indian summer will be interrupted by prolonged spells of drought with devastating effects. Food prices in India and Southeast Asia may climb, millions of people may go hungry, and the stability of governments may be threatened.

If winter snow cover in Tibet can influence the amount of rainfall of the subsequent Indian summer monsoon in this manner, the obvious question to ask is, What causes the variability in Tibetan snow cover? In other words, what lies behind this Tibet connection?

One possible answer relates to the amount of solar heat the plateau reflects to space, and that, in turn, depends to a large extent on the amount of snow that falls on the plateau. When the plateau is widely blanketed under snow, it reflects more of the incoming solar energy back to space than when it is covered with dry grass and barren rock, and this difference in reflectivity produces different effects on the atmosphere. In an ordinary winter, the plateau receives a minimum amount of snow—only a few inches. When the occasional extensive snow cover does fall, the snow, in contrast to the usual barren soil, keeps the atmosphere colder, promotes more storm activity, and increases the chance of additional snowfall. Such conditions disturb the usual position of waves in the jet stream flow and produce such untoward effects as one foot of snow in Tibet in the winter of 1972. But what caused the Tibetan snowfall in the first place?

In studying weather maps from 1960 to the present, I discovered almost by accident that variations in Tibet's winter snow cover matched surprisingly well with sea-surface temperature anomalies over the central North Atlantic during the same periods. When the North Atlantic was excessively warm in the winter, there appeared to be little winter snow in Tibet. A warm North Atlantic tends to attract a persistent high-pressure system, which as it extends into fall, promotes warm, dry weather in Europe and Asia. (This is the kind of weather vintagers love, especially in the Bordeaux area, and as one might expect, there was also a positive correlation between the quality of Sauterne wine grown in that region of France and warmer than normal temperatures in the central North Atlantic.) On the other hand, warm-water anomalies in the Atlantic during autumn and winter promote a trough and ridge pattern over Europe and central Asia that can send Siberian winter storms into Tibet, dumping excessive amounts of snow in that country.

Having found this correlation, I began to search for other possible Tibet connections. A link has already been demonstrated among the delays, weaknesses, and shifts in the Tibetan summer high-pressure system, the Indian summer monsoon, and sea-surface temperatures in the Atlantic. But there seems to be a tie-in with the Pacific Ocean as well. When there are strong summer monsoons in central India and a well-developed high-pressure system over Tibet, the frequency of typhoons in the west Pacific seems to be lessened. When there are many typhoons in the Pacific—some of them bringing excessive rains and flooding to eastern China—the Indian summer monsoon tends to be dry.

In the 1920s, when India was still under British control, British researchers pointed out the existence of a "southern oscillation" in surface air pressures over the land and the sea in the regions between the South Pacific and the Indian Ocean. When the air pressure at Djakarta in Java and in the Indian Ocean was above normal, for example, the Indian monsoon tended to be weak, and the sea-surface pressure in the

South Pacific was below normal. These early studies also suggested a Tibet–Pacific Ocean connection with the Indian monsoon. The intriguing linkages did not stop there, however.

Recent research indicates a correlation between higher than normal air pressure in Djakarta, a drier than normal Indian monsoon, and more than the usual amount of rain in the equatorial Pacific. Under these conditions, the usually strong trade winds may be diminished, and the expected upwelling of nutrient-rich cold water off the coast of Peru, containing plankton on which anchovies feed, may be replaced by a warm, saline water mass. This infrequent event, which tends to arrive after Christmas and has accordingly been called *el niño* ("the child"), kills the plankton and drives away the anchovies, devastating the year's catch and disrupting the world market for those who depend on anchovies as their chief source of protein. (This disruption is, in turn, felt in other protein markets such as the soybean market.)

Thus warm waters off Peru and along the equatorial east Pacific occur simultaneously with higher than normal rainfall in the equatorial Pacific and drier than normal Indian monsoon weather. But warmer than normal Peruvian coastal waters also seem to coincide with warmer than normal water in the usually cold California current, which flows north to south, wells up along the California beaches, and moves water southwest of Baja California into the tropical Pacific. This pattern of sea-surface temperatures correlates with enhanced typhoon activity in the North Pacific, which as we have shown, tends to coincide with an abnormally weak Indian summer monsoon. Some of the loops and circles of the Tibet connection can in this fashion be seen to close.

Still another item of more than curious coincidence has been found. In winters with a strong *el niño* warming of the ocean off the coast of Peru, the stratosphere (the layer of the atmosphere directly above the troposphere) also warms dramatically over the polar regions of the Northern Hemisphere and the normal westerly winds in that atmospheric layer break up into large, wavy patterns. This phenomenon has been called sudden stratospheric warming. Such major warming events apparently occur only in the Northern Hemisphere and seem to be confined to *el niño* winters when the northeastern Pacific also tends to be warmer than normal. Warm waters off the Pacific coasts of the United States and Canada tend to promote the establishment of a strong and persistent high-pressure ridge in the atmosphere over the western seaboard and the Rocky Mountains. This atmospheric flow pattern has a decisive impact on the stratosphere, causing the nearly circular flow there to break down into a wavy pattern of large amplitudes and further strengthening the tropospheric high-pressure ridge. Conditions in January 1977 provided an example of the development of such a ridge, resulting in a major stratospheric flow breakdown and adjustment and in stratospheric warming over the Arctic regions, while the eastern United States shivered in the grip of arctic air.

The foregoing discussion demonstrates the Tibet plateau's far-reaching effect on large-scale wave patterns in the atmospheric airflow over the Northern Hemisphere. The connection between surface temperatures in Tibet and the Indian monsoon has already been mentioned.

Land-surface temperature is, of course, dependent on the amount of heat energy in the form of solar radiation absorbed by the plateau. It is inversely proportional to the plateau's albedo, that is, the percentage of energy it reflects back to space. Fresh snow has an albedo of more than 80 percent, which means that only 20 percent of the sun's radiation energy is available to melt the snow and heat the underlying soil. Dry sand has an albedo of 18 percent, grass-covered ground ranges between 15 and 25 percent, green forests between 4 and 6 percent. A rule of thumb is that the darker a surface looks to the eye, the more radiation energy it absorbs, and the lower its albedo, or reflectivity, becomes.

We know that an increase in the albedo of the Tibet plateau due to extensive snow cover tends to diminish the rainfall over India several months later. In the past, however, some factor other than snow may have affected the albedo of Tibet. Traveling through that region today one cannot help but notice the absence of forests. The Chinese have recently planted trees in and near the villages, but they have to be protected from foraging animals by mud walls. Everywhere one sees people and beasts of burden moving down the mountainsides and across great distances, carrying huge loads of branches and freshly cut junipers for use as firewood. That sight raises the question of whether Tibet's river valleys have been denuded over the centuries by humans in search of fuel. Poor soil conditions, made worse by erosion, are ubiquitous and may have been caused, at least in part, by deforestation.

At present about 1.5 million people eke out a living in barren Tibet, but according to some accounts more than 10 million people inhabited this region during the Middle Ages. Was the land barren then? If so, how did the inhabitants keep warm? It does not seem plausible that the firewood necessary to support a population of more than 10 million could have been carried across the Himalayan passes or through the river gorges of southeastern Tibet, especially since wheeled traffic was hardly known before the recent arrival of the Chinese. Did this large population engage in a massive deforestation of the Tibetan highlands that drastically increased the plateau's albedo?

The answers to these questions are not known, but we can guess that an increase of albedo over widespread regions, from the 4 to 6 percent typical of forested areas to the 15 to 25 percent of grassland terrain that now characterizes the valleys of Tibet, could have produced noticeable effects in the form of decreased summer precipitation over India. Because recorded history does not provide us with easy answers, we have been forced to look for them in computer models of the atmosphere's circulation patterns. Mathematical models are currently being designed to try to establish the Tibet connection in the form of a system of equations that may be useful in forecasting monsoon weather over India. One of the questions these models will test is, Would the climate in Pakistan, India, Southeast Asia, and eastern China, where the existence of millions of people depends on the abundance of monsoon rains, be enhanced by bringing the forests back to Tibet? □

A native of Xigaze, a town almost in the center of Tibet, hauls hard-to-find juniper, freshly cut to use as fuel. Centuries ago, the plateau may have been wooded but it has long been denuded. To improve the fuel situation in Tibet, the government of the People's Republic of China has an active tree-planting program in the province.

Mastodon Memories

In the Hall of Late Mammals at the American Museum of Natural History, four mastodon and mammoth skeletons parade single file down the center aisle. The most famous of this quartet is the third skeleton in line. Called the Warren Mastodon after the scientist who eventually acquired it, it is the remains of a beast that wandered along the shores of the Hudson River perhaps ten or twenty thousand years ago. The animal came to an untimely end in what is now Orange County, New York, by venturing too far into a soggy bed of peat and shell marl.

The skeleton was discovered in 1845 on Nathaniel Brewster's farm in East Coldenham. The summer that year was dry and hot, and many small ponds receded, leaving peat bogs that the local farmers began digging up to fertilize their fields. On the Brewster farm one large pond had dried up, and the enterprising farmer hired a gang of workmen to cut the peat and marl and spread it on his fields. The men had dug about three feet into the bog when one of them struck something hard. Further digging revealed a four-foot-long skull with a pair of gracefully curving ivory tusks. Brewster called in A.J. Prime, a doctor living in nearby Newburgh, who sped down to the Brewster farm in his carriage to supervise the excavation. As the workmen dug, they gradually exposed the beautifully preserved skeleton of a mastodon, standing upright just as it had sunk into the mire thousands of years ago. The skeleton's position gave an indication of the unfortunate animal's final moments: its legs were thrust forward and slightly apart, and its skull was tilted upward as if straining for a last breath of air.

Unlike most mastodon and mammoth bones, which turn black over time, the bones of this mastodon were only slightly stained, giving them a rich brown coloration—"like old human bones," one paleontologist wrote. Although its flesh had decayed and vanished, the contents of its stomach remained. In one of the numerous scientific articles he later wrote, Prime described the discovery of the stomach:

> In the midst of the ribs, embedded in the marl and unmixed with shells or carbonate of lime, was a mass of matter, composed principally of the twigs of trees broken into pieces of about two inches in length, and varying in size from very small twigs to half an inch in diameter. There was mixed in with these a large quantity of finer vegetable substance, like finely divided leaves; the whole amounting to from four to six bushels. From the appearance of this, and its situation, it was supposed to be the contents of the stomach; and this opinion was confirmed on removing the pelvis, underneath which, in the direction of the last of the intestines, was a train of the same material, about three feet in length [and] four inches in diameter.

The delighted Prime had the bones carried to the Brewster barn, and neighbors recall him working for weeks in the gloom of the barn, carefully fitting and wiring the bones together. In classic nineteenth-century fashion, the resultant mounted skeleton went on tour, stopping at small New England and New York towns, where it drew crowds of amazed viewers. The original tusks had crumbled on exposure to the air, so the mastodon was fitted with a large pair of fakes.

The Warren Mastodon was only one find in a series of discoveries ranging back to 1705, when Governor Dudley of New York wrote to that famous Puritan Cotton Mather about several mastodon bones and teeth that had been found near Albany. In 1782, the first Orange County mastodon bones were unearthed on a farm outside Newburgh. George Washington made a special trip to see these bones during his sojourn at Newburgh in the winter of 1782–83. In 1802, a complete skeleton on John Masten's farm near Newburgh was excavated by Charles Willson Peale and his sons Rembrandt and Titian. For years, Peale exhibited the mounted skeleton in his museum in Philadelphia, and then apparently the entire creature was lost.

The Warren Mastodon was the fifth complete skeleton found in Orange County. In *An Outline History of Orange County*, published one year after that find, Samuel W. Eager wrote a glowing account of mastodon discoveries in the area:

> We cannot, without disrespect to the memory of a lost but giant race, and slighting the widespread reputation of old Orange as the mother of the most perfect and magnificent specimens of terrestrial animals, omit to tell of the mastodon. Contemplating his remains as exhumed from their resting place for unknown ages, we instinctively think of his great and lordly mastery over the beasts—of his majestic tread as he strode these valleys and hilltops—of his anger when excited to fury—stamping the earth till trembling beneath his feet—snuffing the wind with disdain, and uttering his wrath in tones of thunder,—and the mind quails beneath the oppressive grandeur of the thought, and we feel as if driven along by the violence of a tornado. When the pressure of contemplation has subsided and we recover from the blast, we move along and ponder on the time when the mastodon lived,—when and how he died, and the nature of the catastrophe that extinguished the race; and the mind again becomes bewildered and lost in the uncertainty of the cause. . . .
>
> Were they pre-Adamites, and did they graze upon the fields of Orange and bask in the sunlight of that early period of the globe?—or were they antediluvian, and carried to a common grave by the deluge of the Scriptures?—or were they postdiluvian only, and till very recent periods wandered over our hills and fed in these valleys. . . .

In 1846, John Warren, a professor of anatomy at Harvard College, bought the mastodon discovered on the Brewster farm for $5,000. He had it crated and shipped to Boston and hired N.B. Shurtleff to remount it for display in his small paleontological collection. A number of famous nineteenth-century scientists came to view the specimen, including Louis Agassiz and the English geologist Sir Charles Lyell. Apparently, Warren was not happy with Shurtleff's mounting, because three years later he hired a Mr. Ogden to dismantle and completely remount the skeleton. Ogden had his own ideas about what a fossil should look like, and he painted the bones with a thick

"It's life as usual in the big wildlife reserve nearby," says Orval Fouse, Supervisor, Utilities & Environmental Engineering at Gulf's Port Arthur, Texas, refinery. "The snow geese still spend a few months here each year during migration. The marshes around the refinery are still full of raccoons, otters, minks, muskrats, even some deer and bobcats.

"To me, that's very good news, because it means they're totally unaffected by the fact that, for the past 20 years, we've been refining what's called 'sour crude.'

"We call it sour because it contains a lot of pollutants. We have to take some sour crude when we buy oil overseas. Of course, we can't release those pollutants into the air. So Gulf spent millions of dollars modernizing this refinery to handle this type of crude. For 20 years now, we've been refining over 100,000 barrels of sour crude a day, and as you can see by the wildlife around here, the air quality is as good as ever."

We have prepared a brochure, "In Search of Balance," on the ways and means of balancing energy and nature. You may have a copy, free, by writing to Mr. William E. Moffett, Vice President, Public Affairs, Gulf Oil Corporation, Department SG, Box 1166, Pittsburgh, Pennsylvania 15230.

layer of black varnish. Next he arbitrarily raised the rib cage and backbone two feet above the shoulder blades, thereby increasing the mastodon's height from nine feet to twelve. Finally he made a brand-new set of gigantic papier-mâché tusks, which swept outward in artistic but purely fictitious curves. In the small museum he had established at 92 Chestnut Street in Boston, Warren exhibited the refurbished mastodon along with his rapidly growing collection of mastodon remains from all over the United States and Europe. In 1906, after a respectable length of time had elapsed since Warren's death, the trustee of the collection wrote to Henry Fairfield Osborn, president of the American Museum of Natural History, and discreetly suggested that the entire collection "might be offered for sale under certain conditions." Osborn, who had had his acquisitive eye on the Warren Mastodon for some time, set out for Boston on the Friday afternoon he received the letter and traveled all night, arriving at the Warren Museum the next morning. Osborn reviewed its treasures with the trustee, Thomas Dwight. They chatted for a while and soon agreed on a price of $30,000 for the entire collection. On Monday, Osborn telephoned his friend J. Pierpont Morgan and asked him to give the Museum $30,000 to buy the collection; Morgan readily agreed, and the skeleton was dismantled and shipped back to its home state.

Before mounting the skeleton, Osborn wanted the black varnish removed. After a number of experiments, Museum technicians built a series of large vats and filled them with benzine in which the bones soaked for many weeks. A final scrubbing with alcohol brought out "all the purity and beauty of color that characterized the skeleton," according to Osborn.

Repairing the original tusks presented a more serious problem. These existed only as two boxes of fragments. The piecing together of the tusks took several months of painstaking and exacting work.

Adam Hermann, the preparator who mounted the skeleton for the Museum, spent a day riding an elephant in a zoo, feeling its shoulder bones and backbones with his hands to figure out how they were related. This information led him to calculate that the height of the Warren Mastodon should be nine feet two inches, and its length from skull to tail should be fourteen feet eleven inches. He posed the skeleton in a walking position, head held high, a reminder of the days, not so long ago, when mastodons roamed the Hudson Highlands.

Douglas J. Preston

Lectures for Adults

The popular fall lecture series will start in October. The lecture courses cover a wide variety of subjects in anthropology, archeology, art, and the natural sciences. The programs will include:

Asian Dancing. Three performances of Asian dance will be given in the Auditorium beginning Monday, October 19. They will be introduced and narrated by Beate Gordon, director of the Performing Arts Program for the Asia Society. *Korean Shaman Rituals and Mask Dances,* performed by Duyee Chang, is the first program in the series. On Monday, October 26, Suarti and Suarni Desar will perform *Balinese and Sudanese Dances,* and Endo Suanda will demonstrate *Sudanese Mask Making.* Concluding the series on November 2, *Eastern and Western Japanese Dance* will be performed by Sachio Ito and Saeko Ichinohe. The price for the three-evening series is $20; tickets may also be purchased separately.

Tibet: The Buddhist Tradition. Three speakers will discuss the culture and religion of this remote land, illustrating their talks with slides and film. Edwin Bernbaum, author of *The Way to Shambhala,* will begin the series of Thursday evening lectures on October 22 with *Hidden Valleys of the Himalayas.* Next, on October 29 and November 5, Franz Michael, professor emeritus of East Asian history and government at George Washington University, will lecture on the cultural history of Tibet. On November 12 and 19, Valrae Reynolds, curator of Oriental collections at the Newark Museum, will speak on Tibet's religion and art. Tickets for the series cost $30.

Audubon Nature Films. Four filmmakers will introduce and screen their latest films about the wildlife of four areas of North America. The first film is Dennis Holt's *Okefenokee, Land of Trembling Earth,* which will be shown on Tuesday, October 20. It examines the animal life of the largest virgin swamp in the United States. On Tuesday, October 27, Richard Kern will show his film, *Florida Cypress Sanctuary: Fishing Creek,* about the seasonal wildlife of this habitat. The third film, on Tuesday, November 10, is *A Naturalist Afield: Part II* by Karl Maslowski, a study of animal behavior in Yellowstone and Grand Teton National Parks. The last film, on Tuesday, November 17, is *Footloose in Newfoundland,* by Thomas Sterling, an exploration of Newfoundland's history, people, and culture. Tickets for the series are $25.

Other subjects in the lecture series are American archeology, wetland botany, and weaving—a total of seventeen courses will be given this fall. Prices range from $20 to $65. Contact the Education Department at the Museum for details and a course registration form.

Discovery Tours

C. Bruce Hunter will lead an in-depth Discovery Tour to the People's Republic of China, from October 24 to November 14, 1981. Limited to twenty-four participants, this intriguing tour focuses on the outstanding art and archeological sites of China. Highlights will include extended visits to Peking, Sian, Nanking, Shanghai, Datong, and Taiyuan.

Two other Discovery Tours to China are being planned for the spring and fall of 1982. For information regarding China programs and other exciting destinations, please write to Discovery Tours at the Museum or call (212) 873-1440.

Workshops for Young People

Five exciting courses this fall will help children explore the world around them. *Photographing New York,* taught by a social scientist and professional photographer, will show students how to take and develop pictures of New Yorkers at work and play. In *Exploring with the Microscope,* children will learn about a variety of cells and microorganisms. Other courses are *The World of Dinosaurs, Reptiles and Amphibians,* and *Human Origins.* The workshops start the weekend of October 25, and cost from $14 to $25.

Night of the Hunter

The Drama of the Universe, the current sky show in the Hayden Planetarium, will close September 14. *Night of the Hunter,* an exploration of the constellation Orion, opens Thursday, September 17.

Planetarium Courses

This fall adults and children can choose from a variety of courses in astronomy, meteorology, navigation, and aviation. Some examples are *Life Beyond the Earth,* which will explain why some scientists believe that intelligent life must exist elsewhere in the universe; *Meteorology,* an introduction to the atmosphere and weather forecasting; and *Cosmos,* based on Carl Sagan's television series. There are a number of basic astronomy courses for young people, including *Introduction to the Sky,* a study of stars and other objects in space. Classes begin at the end of September. For a free course catalog, call (212) 873-1300, ext. 206.

Microhistory

Through the Looking Glass, an exhibition tracing the development of the microscope from its most primitive form to the highly advanced models of the present day, opens in the Akeley Gallery on Wednesday, September 23. Examples from many periods will be on view, with illustrations depicting what could be seen through each. One exhibit deals with the sophisticated scanning electron microscope and includes a videotape showing what this $150,000 instrument can do.

Holy Places and People of India

What draws pilgrims to sacred sites and sacred people?

by Colin Turnbull

Apart from a few professional climbers, only the most devoted pilgrims seek out such inaccessible natural shrines as the Himalayan sources of the Jumna and Ganga rivers. Yet in more accessible places, such as Kashmir and Darjeeling, tourists experience the same sense of awe at nature's beauty. Shrines may be built at such sites, but at best, nature works its miracle of inspiring faith without any human help. Elsewhere, in places where the greatness of nature is less apparent, monuments and temples are built as witness to some suprahuman greatness. There is nothing special about the holy river Ganga at Varanasi (Benares); the countryside is the same flat expanse of farmland that follows the river's course throughout the plains. But at Varanasi, the river, which once it has descended from the northern mountains runs mainly from west to east, turns and briefly flows from the south back up toward the north. Every morning it seems as if all of India's millions descend the ghat steps in the sacred city of Varanasi and enter the water to perform *surya-pranam,* welcoming the rising sun and chanting the sacred *gayatri* mantra. At that time Varanasi is one of the most beautiful cities in the whole of India, particularly for the pilgrim. For the tourist, however, it may forever remain merely one of the dirtiest.

Grossly overcrowded, Varanasi is marked by disease and poverty; the most luxurious palaces have an unkempt and shoddy look about them, and the temples are no architectural wonders. What attracts pilgrims by the millions is something very human, rather than divine, but sacred nonetheless: the ancient history of at least three thousand years of uninterrupted faith that has permeated the city from its holiest shrines to its filthiest residential areas. In Varanasi, crime, poverty, disease, and sanctity walk together with confounding ease and assurance in a strangely inoffensive kind of mutual support. Man and man's unquenchable faith give the city this quality; the very squalor that would otherwise only repel is transformed into a honeyed bait that, throughout the ages, has attracted India's greatest, as both tourists and pilgrims.

Other holy cities have arisen in areas that have even less to offer by way of natural wonders than Varanasi, but have been chosen to become great political centers. One such city, Khajuraho, capital of the Chandela dynasty, reached its height in the tenth century. Today, out of some eighty-five great temples, only twenty-two survive. Khajuraho is now a dead city, a national park opened up and managed for the exclusive use of tourists attracted by the erotic carvings that seem to cover every square inch of the ornate structures. Most of these tourists, Indian and foreign alike, fail to visit the nearby village, which—taking pride in its sudden rise to fame again after centuries of neglect—has turned itself into one of the cleanest and most attractive villages in India. And surprisingly few of the foreign tourists take more than a second look at a temple that stands just outside the entrance gateway where you pay your admission fee, only a stone's throw from the first temple within the tourist compound. Although it looks much like all the others, this temple is alive. Anyone who climbs the long flight of stone steps as night falls will witness the worship of a gigantic, eight-foot carved stone phallus, or *lingam,* a form of worship that transforms what is politely referred to as erotic art from tourist pornography into a surging, massively powerful religious quest. The *puja* performed in the inner sanctum of that temple attacks all the senses at once; it transforms one's whole being in an experience that at first seems entirely physical, but that culminates in a gentle act of blessing, an offering of food and water, a touch of a finger on the forehead—so soft that only the eyes of the priest tell you it has been done. With all the evidence of erotica around, an objective observer might construe the *puja* itself as erotic, particularly at its loudest, when the temple drums seem to force the body to move, even to dance. Some tourists do indeed think so—from the outside steps. But a few, those who want to understand rather than just observe, climb the steps, enter the shrine, and find, to their surprise, that they are made as welcome as pilgrims and treated with the same respect. Shrines need people to bring them to life and give them meaning.

Another tourist resort that used to be a major pilgrim shrine is Mahabalipuram, on the west coast, south of Madras. Here as with the Chandela capital, Khajuraho, the faith that caused the temples and rock shrines to be built is mute, and the only form of worship is that practiced by tourists with their cameras. Yet not far inland is Kanchipuram, whose many temples, separated by miles of busy streets, are filled with pilgrims from morning to night, testifying to the magnitude and vitality of pilgrimage as a social institution. The temples also testify, in more ways than one, to the similarity between pilgrimage and tourism.

Each of the larger temples consists of five walled courtyards, laid out one within the other. Each wall is pierced by a huge gateway surmounted by a richly decorated *gopuram,* or "tower," which soars up into the sky. The towers lead the spirit upward as they lead the body inward, and the mood of the pilgrims is one of excitement and expectancy, precisely that of tourists arriving at their destination. There is an urge to accomplish, to see all there is to be seen, to do everything there is to be done. In some temples the outermost courtyard may be filled with attractions; in others it may just be a narrow empty space, somewhat like the moat surrounding a castle. On either side of the first gateway there are invariably stalls with vendors selling their wares: guidebooks to the temple, scriptures, writings by holy people associated with the temple, garlands of flowers to offer at the various shrines within. And, of course, there are guides everywhere, waiting like hawks for the unwary.

Most of the pilgrims pass on through an empty outer courtyard and enter the next *gopuram,* eager to get to the shrines. They jostle each other, joke and laugh, pose for photographs. But a few, in a more reflective mood, just stand on the inside, looking up at the next gateway, reading its intricately carved face as though it were a book, letting each image tell its story. And of these reflective pilgrims, a few will then begin the *parikrama,* or "circumambulation," of the outer courtyard, walking slowly in the prescribed clockwise fashion. Sometimes the outer walls are surmounted by a seemingly endless succession of carved bulls; otherwise there is nothing to look at except the bare stonework and the sky above. Like tourists, all the pilgrims have been drawn by the same outer objectives—to see the same sights, enjoy the same spectacles, participate in the same pleasurable activities—but each does it in his or her own way, each finding the essence that makes the visit worthwhile. Nevertheless, it would be a mistake to classify the pilgrim as religious and the tourist as secular. The tourists who, rather than going straight into a casino, stop to enjoy the gardens outside, might be said to be closer to a religious experience than those pilgrims who purchase a garland of flowers at the outer gate, head straight through to the innermost shrine, and so to speak, place their bet on the altar before doing anything else.

Nor should the various ritual observances that many pilgrims perform make it seem that they are exclusively devotional. The pilgrim slowly circumambulating the temple's first empty courtyard, quietly chanting the scriptures, may be just as excited as any tourist. Some may even have to work hard to keep their minds on the sacred and avoid the distractions of the many sideshows the larger temples have to offer. There is, for instance, a particularly arduous way of performing the *parikrama,* which really should be done in each courtyard until the central shrine itself has been reached. Prostrated full length, face down on the ground, arms outstretched, pilgrims inch their way upward and forward until they are standing where their hands had touched; then they prostrate themselves again. This practice, called *sashtanga danda pradakshina,* is not often seen. On the few occasions that it can be observed, however, it appears to be not a penance but rather a way of savoring the pleasure of pilgrimage to its fullest, of exhausting every possible delight before coming to the greatest joy of all, *puja* at the main shrine, which becomes a veritable ecstasy.

The more obvious enjoyments are many. In some inner courtyards there are huge pillared hallways that may be used as bazaars where shopkeepers sell replicas of the various shrines, colorful pictures of scenes from the Hindu mythology, icons carved from stone or sandalwood, rosaries, and other religious mementos that pilgrims take home, like tourist trinkets, to remind them of a special and sacred moment in their lives. But there are also things to take back to enrich normal, daily, secular life: clothing to be worn every day, shoulder bags in which to carry schoolbooks or the day's shopping, bright jewelry with not a trace of religious symbolism. All these serve as a reminder of sanctity, just as vacationers like to have something to remind them of their "holiday," a word that is, after all, derived from the Old English *haligdaeg,* or "holy day."

Some temples house elephants or other animals; many have whole areas filled with monkeys. The animals provide entertainment, and the elephants, in particular, are paraded frequently for the crowds to watch. (Once in a while elephants are hitched to enormous chariots that carry sacred images from the temple out into the streets.) There may also be bathing tanks or special wells from which, according to inclination and means, the pilgrim can drink or be sprinkled or thoroughly drenched with holy water. The temple as a place of entertainment is one of the

INDIA.
WHERE WE ARE
DIFFERENT.
WHERE WE ARE
THE SAME.

Meet men who walk in holiness

Our cities are exciting mixtures of the old and new

India. An unbelievable experience.

We are as different as you hope.

Come to us and view palaces, tombs, fortresses. Shop in brilliant bazaars. Enjoy our art, listen to our music, feel our dances.

You will see sights you've never seen, new colors and shapes. You will hear new sounds, taste new tastes.

But we have another surprise for you, too.

We are the same as well as different.

We can make you extraordinarily comfortable. You'll stay in modern, air-conditioned hotels. Play golf, tennis. Swim in cool pools.

And most of our people speak English.

Come to us on one of the many, many tours offered. We'll make you feel very different. And very much at home.

best shows on earth. But always, there is another open courtyard, and in every direction are those huge towers reaching up into the sky, leading the pilgrim on to the innermost shrine.

At the very entrance to that shrine, in the darkest recesses, the holiday-making atmosphere may still prevail. But there is a different quality to the sound and to the light, the aroma of incense or fresh jasmine pervades the shadows, and the stone floors feel especially cool to the pilgrim's bare feet. Most delay their entrance into the shrine by making the final *parikrama.* This last inner court, covered by a heavy stone roof, sometimes painted and always rich with carvings, is lit mainly by openings that pierce the walls at the ceiling, letting in shafts of sunlight. Today there is an occasional fluorescent light, fed by straggling wires, sputtering away as if gently mocking the futility and inadequacy of modern technology.

The pilgrim may walk around that inner courtyard several times, preparing for the ultimate experience of the pilgrimage, but there is nothing sanctimonious about this. In most cases the scene looks more like a crowd of people milling around, finding something to do until the box office opens and admits them into the movie house. And when the pilgrim emerges there is still no smugness. I saw no one who appeared to have achieved instant enlightenment, but a transformation *had* taken place. The most common manifestation was a quality of effervescence. Those with cameras immediately got their friends or some bystander to take a picture of them at the entrance, beside the sign that says "No Photography Beyond This Point." Not once did I see anyone photographed *before* going into the inner shrine.

There are, of course, many different kinds of man-made shrines other than temples. Frequently, Muslim, Hindu, Buddhist, and Jain shrines can be found huddled together, combining their diverse efforts to sanctify the same place, as at Rajgir, nestled in the hills between the ancient Buddhist university of Nalanda and the place of the Buddha's enlightenment, at Buddh Gaya. There it is impossible to be exclusive about religion, and gaudy pictures of Christian figures and saints are on sale alongside similar pictures of Indian deities. A Muslim mosque looks across to hot springs, sacred to Hindus, lying at the base of a hill sanctified by Jains and Buddhists alike.

Sometimes man glorifies himself, perhaps unconsciously, by carving gigantic images of holy people, such as the enormous sitting, standing, or recumbent figures of the Buddha and other teachers. One of these, at Sravanabelagola in a remote, hot, and dusty part of southern India, is reached by climbing a precipitous flight of six hundred steps cut into the rocky mountainside. The sixty-foot high image of a Jain epic hero, Gommateswara, is set back on the summit and cannot be seen from below: even on reaching the top, the pilgrim has to pass several other shrines and through the wall of a large courtyard before reaching the ultimate goal. There two immense feet planted in a huge lotus seem to dare the pilgrim to look upward and meet the eyes of Gommateswara. A priest at this shrine told me that some pilgrims never look up; they perform *puja* at the feet and find that is enough. "It is not everyone that wants to look up and reach that high," he said. And indeed, as pilgrims, young and old, arrived, some of them barely gave the gigantic figure as much as a glance. That was not what they had come for; they had come to worship where pilgrims had come for a thousand years. It is the power of these images—or of living saints and other sacred people—to inspire devotion in the living that draws the pilgrims; the pilgrimage is a manifestation of that devotion and is more important and perhaps even more sacred than the shrine itself.

This helps explain the attraction of so many of India's pilgrims to "holy men," some of whom are known to be charlatans, brazen tricksters, or commercial performers and who seem to be anything but holy. Like the tourist who knows that he has been taken, the pilgrim has at least had an experience he would not have had otherwise. The tourist determined to find enjoyment will find it no matter what; pilgrims who seek spiritual growth or some other kind of religious gain can win by pitting themselves against the quacks and frauds they are bound to meet on the pilgrim trail. Many a shrewd trickster, claiming to be divine, asserts that he deliberately assumes a gross form and surrounds himself with the trappings of degeneracy in order to test his disciples. It is a difficult argument to counter. Thirty years ago, the best-known of the living teachers assiduously refrained from any semblance of trickery, pretended to no miracles, and were untouched by the slightest scandal. But today the best-known gurus are highly controversial, some openly perform sleight of hand when they appear in public and even make sexual advances in private.

There is no precise counterpart in tourism to this third kind of pilgrimage, the pilgrimage to sacred people. Tourist resorts do indeed sometimes grow up around the place of the birth or death of famous people and become sites of secular pilgrimage to honor heroes. But there is nothing quite like the pilgrim's quest for contact with a living person touched with power.

The extent to which India's gurus open their homes, or ashrams, to the public varies. In the course of my research at Benares Hindu University I visited most of the best-known ashrams and, probably because of my work, was readily given access to the teachers themselves. But that is not always the case. Anandamayi, for instance, who was my teacher for two years, went to great lengths to escape the public. At a moment's notice she would make her way to the nearest train station and take off for some destination, perhaps hundreds of miles away. It took a particularly devoted pilgrim to follow that kind of trail.

Down in Mangalore, on the west coast, Swami Ramdas used to tell pilgrims who sought him out to go and climb a nearby mountain every dawn and learn from watching the sunrise. That was just about as far as I ever got with him, but at least his disciples made me welcome, and I, together with other pilgrims, was free to participate in all ashram activities (provided I had watched the sunrise from the mountaintop). In Tamil Nadu, however, the disciples of Sri Raman Maharishi kept tight control over all pilgrims seeking their master out in his retreat near the sacred mountain Arunachala. In his old age Maharishi never moved from his quarters, and even disciples seldom got inside to see him. Perhaps that is what made it possible for the great man to be so warm and easy with those who did make it through the defenses, giving them so much of his time, wisdom, and strength.

When I last saw Maharishi, he was dying of cancer, and so last year, nearly thirty years after his death, I went back to see what had happened to his ashram as a place of pilgrimage. Even the town of Tiruvannamalai, with its magnificent temple covering some twenty-five acres, had changed. Because it is still as inaccessible as ever, the number of pil-

grims has not increased much, but the quality of the experience it offers is different. For pilgrims who do not want the admittedly severe austerity of *dharmashala,* there are now hotels as well. The temple has been fitted with electric light, changing the mood of much of the interior, removing much of the mystery it held when it was lit only by flares, butter lamps, and occasional shafts of sunlight. The ashram, no longer with a saint to protect, accepts paying visitors, and a large entrance gateway, laced as it was with palm fronds, reminded me of the entrance to a tropical island holiday camp. A richly elaborate altar over the tomb of the dead teacher is set in an ornate, cold marble hall, a stark contrast to the warm, quiet simplicity of Maharishi's life.

I also visited the ashram of another great saint who had died not long after I last saw him, back in 1950. Sri Aurobindo was one of India's three most highly respected religious leaders. Before becoming a "sacred person," he had been a university professor and a political activist; as a result of his political activity, he had spent time in jail. He believed it was possible for humans to reach up and raise themselves above their present level, bringing about the rule of the Divine on earth. This was to be no easy endeavor, and Sri Aurobindo established an ashram in Pondicherry where his disciples underwent rigorous training of mind and body, as well as soul. He himself was more of a recluse than any of the other great teachers, appearing even to his disciples only once a year, for a brief *darshan,* or "audience," to which pilgrims came from all over the country. His presence was felt so powerfully throughout the ashram, however, that pilgrims actually came at all times of the year, not just for the one day of *darshan.* To be in the actual presence of the man was almost unbearable, and although I was a total skeptic at the time, when his eyes met and held mine I immediately developed a violent headache that lasted the rest of the day. I could understand why some pilgrims preferred not to come for *darshan,* just as some did not want to look up to the eyes of Gommateswara, sixty feet above them, and perhaps why some tourists even seem to hold themselves back from certain experiences, as though afraid that they might rupture the normality of the everyday world to which they must return.

I was not surprised to find that despite the death of Sri Aurobindo so

The Amazing Stirling Cycle **Hot Air Engine**

7¼" x 4"

Heat is the only fuel required!

This miniature Stirling Cycle Engine measures 7" x 4¼" and comes complete with built-in alcohol burner. Red flywheels and chassis mounted on a green base, these all-metal beauties silently running at speeds in excess of 1,000 RPM attract attention and create awe wherever displayed. The model comes completely assembled and ready to run, accompanied by our "Stirling Cycle Engines" book. This is one of a series of four model hot air engines now available.

Experimenters • Hobbyists' Power Source
Students • Collectors • Model Engineers

An easily read, lavishly illustrated, 128-page book accompanies each engine or may be purchased separately. This publication, the first of its kind, takes the reader on a 160-year tour through the world of Stirling Cycle Engines.

Women of the Andes

Patriarchy and Social Change in Two Peruvian Towns

The place is Peru. The characters are the women of two highland communities. The book is a study of their lives and of the cultural implications of gender difference. It identifies those attitudes which serve to perpetuate the subordination of women — and those points at which women assent to their own repression. A volume in our Women and Culture Series.

many years ago, nothing seemed to have changed at the ashram. Visitors of all kinds are equally welcome, even the merely curious. For those not willing to accept the full discipline of the inner ashram there are separate residences, and as before, they are always occupied. The atmosphere is still like that of a holiday camp. At Sri Aurobindo ashram, peer pressure compels all to devote time and energy each day to physical exercise, either sports or calisthenics, as well as pursuing some course of academic study and dedicating some hours to group and private meditation. As with some other ashrams, many Indians (regardless of religion) come here for their vacations and speak of their one- or two-week stay as a holiday, and nothing more. The place, the atmosphere, the communal activities make them "feel good."

Although the ashram itself has not changed that much in thirty years, it stimulated a change in the local community that, at first, promised to be spectacular. In the belief that "there should be somewhere on earth a place . . . where all human beings of goodwill . . . could live freely as citizens of the world and obey one single authority, that of the supreme truth," the ashram founded a separate community, Auroville, or City of Dawn, a few miles up the coast. The concept received the enthusiastic support of UNESCO, which encouraged its member states to participate in "the development of Auroville as an international cultural township." Volunteers quickly came forward, including a European architect who drew up an ambitious plan, and a throng of untrained but dedicated youth willing to contribute their labor. In February of 1968 the foundation stone was laid. Young people came from 23 Indian states and from 121 countries. All brought a handful of soil from their home country, and placed it in a marble lotus urn in the new amphitheater, dedicating their young lives to a dream come true—a paradise on Earth. On completion the City of Dawn was to house some 50,000 international citizens, a vast human experiment in the conscious evolution of a new and better way of life.

Near the central amphitheater would tower an extraordinary shrine, the Matri Mandir, or Mother Temple. This vast golden sphere, raised up into the sky on four pillars, was to contain twelve inner and four outer gardens and a huge meditation hall, open to the sky. Work on this and other projects

was eagerly begun—and then the dream began to turn sour. A pilgrim resort, much like a tourist resort, may or may not be a blessing to the local community. Too much depends on the highly variable and fluctuating quality of the pilgrims/tourists themselves, on what they import with them and what they leave behind. Unfortunately, Auroville quickly attracted some of the youthful flotsam of America and Europe, young people who felt that the world owed them a life of nothing but ease and pleasure. They also had an ideal of sorts, but it was far different from that of the founders of Auroville. Instead of a life of discipline, dedication, and service, they wanted nothing more than to live under the palm trees on the beaches, free to indulge in the latest fashions in sex and drugs. Drug smuggling brought in the police, the excess of freedom brought anarchy, and many of the dedicated Aurovillans simply left to pursue their dream elsewhere. All construction work stopped, and by last year, the amphitheater was overgrown with weeds and inhabited only by snakes and lizards. The farmland was a desert; the roads all but impassable. The great Matri Mandir rears its framework up into the sky, an ugly skeleton of unfinished concrete and rusting steel. The population has shrunk to a bare handful, rent by dissension and charges of racism, bigotry, profiteering, and immorality. Auroville stands as a monument to the emptiness of a dream in which discipline and total dedication had no part.

While both pilgrimage and tourism involve hard realities for communities that become resort centers, they have more than this in common. They both stimulate dreams that, however unmatched by reality, have the ability to enrich and enlighten, giving the dreamer fresh hope and fresh life. Unlike reality, dreams do no harm to others, and more often than not, they do incalculable good in terms of both social and spiritual consciousness. There is no question as to the social benefits of pilgrimage in India, and insofar as dreams are the stuff that tourism, at its best, is made of, we have to admit of at least the potential of spiritual benefit from tourism. India shows us just how closely tourism and pilgrimage are connected.

Colin Turnbull, formerly associate curator of African ethnology at the American Museum of Natural History, is visiting professor of anthropology at George Washington University.

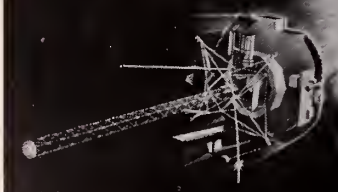
Come explore a comet.

Halley's Comet returns in 1985. The Europeans, the Soviets, and the Japanese are readying spacecraft to meet it. Our nation plans to watch from afar because NASA has no money for a Halley mission even though only the U. S. has the technology needed to fully probe this comet for the clues it offers on



the origin of our solar system. We stand to lose not only knowledge, but also new technologies and a bit of our prestige.

Last year 10,000 people used the Viking Fund to show their support for space exploration. They contributed an average of $10 apiece to help one starving project: the Viking lander on Mars.

Now the Viking Fund's organizers announce the Halley Fund. By donating to this new fund, you'll let Washington know you want a U.S. probe of this comet. Your money will help pay for the mission, for Halley studies from the shuttle, and for U. S. participation in the International Halley Watch.

So come explore a comet, but don't delay. Your next chance to contribute to a Halley fund won't come until the year 2062.

THE HALLEY FUND

Celestial Events

by Thomas D. Nicholson

The Moon The very early crescent moon highlights the gathering of Venus, Jupiter, Saturn, and the star Spica in the western sky on September 1 and 2. The late crescent moon passes very close to Mars during the morning of September 24, covering the planet (an occultation) over parts of the Southern Hemisphere. Phases are: first-quarter on September 6, full on the 13th, last-quarter on the 20th, and new on the 27th. First-quarter occurs again on October 6 and full moon on the 13th. Apogee (farthest from the earth) is on September 5 and October 2 and 30; perigee (nearest the earth) is on September 16 and October 14. The full moon on September 13 is the harvest moon, that on October 13 is the hunter's moon. On both occasions, the full or nearly full moon rises only about half an hour later each night for several days in a row, as compared with the average delay of about fifty minutes.

Stars and Planets Early in August, Venus is near Jupiter and Saturn, all in the west during twilight. Venus, the brightest, appears about half an hour after sunset, then Jupiter appears, and finally Saturn, to Jupiter's right. By then you can also see Spica, in Virgo, to the left and above Venus and about as bright as Saturn. All of them set at about the end of twilight. After the first of the month, Venus creeps slowly toward Spica, passing above it on the 6th, then moving away, meantime separating from Jupiter and Saturn as they set earlier each night until, by midmonth at the latest, they are too low to be visible in the twilight. Venus continues to set at about the same time, relative to sunset. In the morning, Mars becomes more favorably placed, rising about four hours before the sun. But it still isn't much brighter than a second-magnitude star, such as Polaris, the North Star. It will begin to brighten dramatically in November, and should be a fairly prominent object this coming winter. On September 15, the sun moves from the constellation Leo into Virgo, joining the five planets already in Virgo—Mercury, Jupiter, Saturn, and Pluto, there all month, and Venus, there until the 19th. Uranus, in Libra, and Neptune, in Ophiuchus, are not far from Virgo's

eastern border. All of these planets are east of the sun, which makes them evening stars. Even Mars, in Cancer, the one vagrant in the morning sky, is only about 50 degrees from Virgo's western border.

In mid-September, the sun joins five planets (Mercury, Venus, Jupiter, Saturn, and Pluto) in Virgo, with Uranus and Neptune nearby in Libra and Ophiuchus. All are evening stars. Even Mars, the one wanderer in the morning sky, is not far to the sun's right. Is this an unusual planetary alignment? Yes, but it is of significance only to skywatchers. Rumors about an impending alignment of planets in 1982 are puzzling to astronomers. No close "lineup" will occur, and even if one did, it would go unnoticed unless it were called to your attention.

¡Speak Spanish like a diplomat!

What sort of people need to learn a foreign language as quickly and effectively as possible? *Foreign Service personnel*, that's who. Members of America's diplomatic corps are assigned to U.S. embassies abroad, where they must be able to converse fluently in every situation.

Now *you* can learn to speak Spanish just as these diplomatic personnel do—with the Foreign Service Institute's Programmatic Spanish Course.

The U.S. Department of State has spent tens of thousands of dollars developing this course. It's by far the most effective way to learn Spanish at your own convenience and at your own pace.

The Programmatic Spanish Course consists of a series of tape cassettes and an accompanying textbook. You simply follow the spoken and written instructions, listening and repeating. By the end of the course, you'll find yourself learning and speaking entirely in Spanish!

This course turns your cassette player into a "teaching machine." With its unique "programmatic" learning method, you set your own pace—testing yourself, correcting errors, reinforcing accurate responses.

The FSI's Programmatic Spanish Course comes in two volumes. You may order one or both courses:

☐ Volume I, Basic.
(12 cassettes, 17 hours), instructor's manual and 464-page text, $115

☐ Volume II, Intermediate.
(8 cassettes, 11½ hours), instructor's manual and 614 page text, $98

(New York residents add sales tax.)

Your cassettes are shipped to you in handsome library binders.

TO ORDER, JUST CLIP THIS AD and mail with your name and address, and a check or money order. Or, charge to your credit card (American Express, VISA, Master Charge, Diners Club) by enclosing card number, expiration date, and your signature.

The Foreign Service Institute's Spanish course is unconditionally guaranteed. Try it for three weeks. If you're not convinced it's the fastest, easiest, most painless way to learn Spanish, return it and we'll refund every penny you paid! Order today!

Many other FSI language courses also available. Write us.

599 College Ave. • Dept. N • Palo Alto, CA 94306 • (415)494-6572

August 31–September 2: The moon passes Saturn, Jupiter, and Venus during the night on Monday, moves between Venus and Spica on Tuesday night, and then moves away from Spica on Wednesday. The three planets and the star will all set within two hours of sundown.

September 5: Look below the crescent moon tonight for the reddish star Antares, in Scorpius.

September 6: Venus moves from right to left past Spica.

September 7: The "teacup" arrangement of eight stars below the gibbous moon identifies the constellation Sagittarius.

September 13: Tonight's full moon is the harvest moon. It seems to illuminate the early nighttime for several nights in a row, making it particularly useful to farmers staying up late to finish the late summer harvest.

September 19: The waning gibbous moon rises after 10:00 P.M. in Taurus, about midway between the Pleiades ("Seven Sisters") and the reddish star Aldebaran, in the V-shaped Hyades.

September 22: The sun arrives at the autumnal equinox, a point in the constellation Virgo, at 10:05 P.M., EST, and autumn begins officially in the Northern Hemisphere.

September 23: Mercury is at greatest easterly elongation, ordinarily placing it in the best position to be seen as an evening star. But this is an unfavorable elongation. The planet is too low at sunset to be seen.

September 23–24: The moon rises about two hours after midnight (standard time), with the planet Mars below the crescent.

September 26: Although the autumnal equinox occurred on the 22nd, this is the day when the sun spends twelve hours above the horizon and twelve hours below.

September 29: The early crescent moon is in conjunction with Mercury, but the planet is too far south of the moon and sets too early to be seen.

October 1: Venus is easily located below the crescent moon tonight.

October 5: Saturn is in conjunction with the sun and becomes a morning star.

October 6: Mercury becomes stationary among the stars and begins moving westerly (retrograde).

October 13: Tonight's full moon is the hunter's moon.

October 14: Jupiter is in conjunction with the sun and enters the morning sky.

AMERICAN MUSEUM OF NATURAL HISTORY
Vacations on sea and land with Museum Lecturers

INDONESIAN ODYSSEY: Cruise through the paradise islands of Bali, Java, Komodo, Sulawesi, Lombok, Flores, Butung, the Moluccas and Luciparas aboard the luxury vessel, *Regina Maris*. Share with a Museum astronomer, anthropologist, ornithologist, geologist/volcanologist, and herpetologist a unique, in-depth travel experience. The itinerary takes you to lush tropical landscapes with exotic peoples influenced for centuries by India, Islam and Europe.

NILE CRUISE: Explore the astounding ancient sites and natural wonders of Egypt with a Museum geologist, ornithologist/illustrator, and Egyptologist. Cruise 600 miles on the Nile from Cairo to Assuan aboard the custom-built, air-conditioned *Nile Star* stopping at all the important sites which have intrigued visitors since their construction.

GALAPAGOS ISLANDS CRUISE: Discover a special natural world with fantastically tame and exotic animals such as sea lions, giant tortoises, marine and land iguanas and countless rare and beautiful birds. Enjoy the expertise of a Museum ornithologist and herpetologist and four local naturalists as we cruise through this equatorial archipelago which so influenced Darwin.

ADRIATIC AND AEGEAN ADVENTURE: Relive the great historical travels of the Greeks, Romans, Phoenicians and Venetians. Follow their paths on a classical cruise starting in Venice and going to Dubrovnik, Corfu, Corinth, Crete, Rhodes, Tunis, Carthage, Malta, Sicily, Pompeii, Herculaneum and Naples. The *Orpheus* will be your home for 14 beautiful days; the Museum faculty will be outstanding.

LAND PROGRAMS: Seven outstanding overland itineraries have been custom-designed for small groups of 15-25 participants. Famous and remote sites and cultures are discovered while staying at the finest accommodations available with expert Museum Lecturers.

Red Colobus (p. 36)

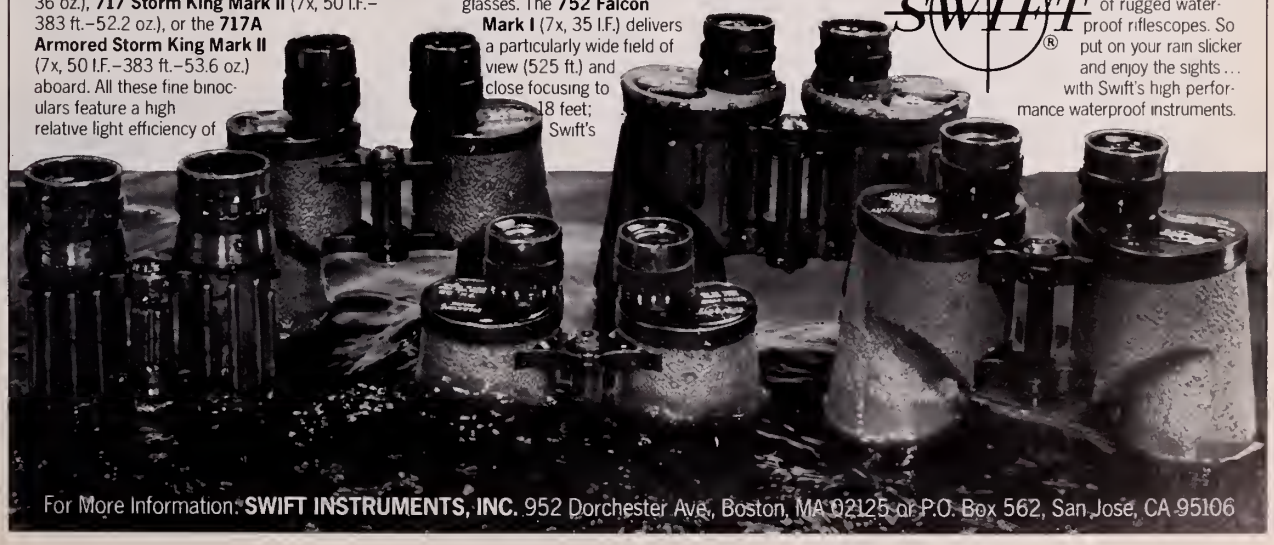
The Red Colobus Monkey, by T.T. Struhsaker (Chicago: University of Chicago Press, 1975), is a detailed account of this primate's social behavior and structure. Struhsaker spent twenty-seven months in Kibale Forest in western Uganda, studying colobus intragroup and intergroup social interactions, population structures and densities, food habits, and ranging and activity patterns. Although he focuses primarily on one group of *Colobus badius tephrosceles*, he also provides data on other groups and subspecies, including *C.b. temminckii*. This volume, part of the "Wildlife Behavior and Ecology" series, edited by G.B. Schaller, also has sections devoted to vocalizations and ecology and a bibliography. A more general work is T. Rowell's *Social Behaviour of Monkeys* (London: Penguin Books, 1972), which explores social organization, field and captive environments, intergroup communications, and concepts of hierarchy, territory, and roles. Drawing from her own work with wild baboons, Rowell also gives a general account of other monkeys, emphasizing the African Old World species. Much information is given on colobus, vervets, and patas monkeys. In *The Langurs of Abu* (Cambridge: Harvard University Press, 1977), S. Blaffer Hrdy studies female and male reproductive strategies in another member of the subfamily Colobinae. Her book covers encounters between troops, invasion strategies, competition among females, infant sharing, infanticidal males, and female counterstrategies. It also discusses other colobines. The twenty-eight articles in *Primate Ecology*, edited by R.W. Sussman (New York: John Wiley and Sons, 1979), represent some of the earliest attempts at problem-oriented field research. The section on Old World monkeys includes an article by T. Struhsaker and J.F. Oates, "Comparison of the Behav-

ior and Ecology of Red Colobus and Black-and-White Monkeys in Uganda: A Summary" (pp. 165–209), and "Primate Social Organization and Ecology," by T. H. Clutton-Brock (pp. 503–12). A profusely illustrated, nontechnical summary of the primates, G.H. Bourne's *Primate Odyssey* (New York: G.P. Putnam's Sons, 1974) contains sections on the Old World monkeys, including the colobus. More technical is *Old World Monkeys*, edited by J.R. Napier and P.H. Napier (New York: Academic Press, 1970), a collection of nineteen articles on the anatomy, evolution, ecology, behavior, ethology, and taxonomy of this family.

Saturn (p. 44)

The New Solar System, edited by J.K Beatty, B. O'Leary, and A. Chaikin (Cambridge: Sky Publishing Corp., 1981), is a collection that brings together the most recent findings about the sun, planets, satellites, and that which lies between. This up-to-date reference work, with an introduction by C. Sagan, includes the first *Voyager* encounter with Saturn and offers coherent explanations of the chemical and thermal history of the solar system, the accretion and fragmentation of its members, and the changing planetary surfaces. Among its twenty articles are "Jupiter and Saturn," by A. Ingersoll, and "Titan," by J. Pollack. The 10 April 1981 issue of *Science* features twelve articles, occupying from pages 159 to 239, that deal with different aspects of the *Voyager* mission to Saturn. It presents the first scientific reports of the flyby of the planet and its satellites and rings, illustrated with many informative photographs, charts, and graphs. *Voyager 1 Encounters Saturn* (Washington, D.C.: U.S. Government Printing Office, 1980, Stock No. 033-000-00817-1), available for sale from

WHETHER RAIN, FOG, OR SUDDEN SQUALL...
Swift Waterproof Binoculars Shine Through.



When weather conditions are less than perfect, see your way clear with Swift quality waterproof binoculars.

Seafarers are always prepared with Swift's **753 Sea Hawk Mark I** (7x, 50 I.F.–393 ft.–36 oz.), **717 Storm King Mark II** (7x, 50 I.F.–383 ft.–52.2 oz.), or the **717A Armored Storm King Mark II** (7x, 50 I.F.–383 ft.–53.6 oz.) aboard. All these fine binoculars feature a high relative light efficiency of 84.2, producing razor sharp images even during that unpredictable storm-at-sea.

Sports fans and ornithologists can enjoy the action even under the most adverse conditions when "armed" with Swift's quality waterproof glasses. The **752 Falcon Mark I** (7x, 35 I.F.) delivers a particularly wide field of view (525 ft.) and close focusing to 18 feet; Swift's **820 Armored Trilyte Mark III** (9x, 35 I.F.) offers maximum hand-held power in a compact (26 oz.) wide-field (383 ft.) instrument.

SWIFT®

Swift also has an extensive selection of rugged waterproof riflescopes. So put on your rain slicker and enjoy the sights... with Swift's high performance waterproof instruments.

CHIPMUNK PORTRAIT

by
B. & H. Henisch

THE CARNATION PRESS
State College, Pennsylvania

An illustrated study of chipmunks and their habits, their discovery in America by early European explorers and naturalists, and their role in the art and folklore of the American Indian.

"Delightful, scholarly, irresistible" (*Scientific American*). "Outstanding title; impossible to bypass; well researched and documented" (*Library J.*) "A certified delight" (*House Beautiful*). "Important contribution" (*J. General Education*).

the Superintendent of Documents, Washington D.C. 20402, presents the preliminary photographs, accompanied by straightforward, nontechnical explanations, from *Voyager 1*'s encounter with Saturn and its major satellites. "Voyager 1 at Saturn: Riddles of the Ring," by senior writer R. Gore (*National Geographic*, July 1981, pp. 2–31), is a popular account of the *Voyager* mission to Saturn, featuring many color photographs from NASA.

Suriname (p. 54)

S. Price and R. Price's *Afro-American Arts of the Suriname Rain Forest* (Berkeley: University of California Press, 1980), is the first comprehensive study to explore the integration of the arts in everyday Maroon life and trace their development from Africa to the Suriname rain forest. The book has more than 300 duotone illustrations and 21 color plates. A special, NEH-subsidized edition can be purchased from the Museum Shop of the American Museum of Natural History for $8. The Prices have also produced a recording of Maroon music, with extensive ethnographic notes, *Music from Saramaka: A Dynamic Afro-American Tradition* (New York: Folkways Records, 1977). For a general overview of Maroon societies throughout the Americas—from Brazil through the Caribbean and into the southern United States—see R. Price's *Maroon Societies* (Baltimore: The Johns Hopkins University Press, 1979, revised edition). Two books by M.J. Herskovits and F.S. Herskovits, pioneer anthropologists in Afro-American studies, describe their visits to Suriname in the 1920s. *Rebel Destiny* (New York: McGraw-Hill Book Co., 1934) chronicles their two trips to the Saramaka Maroons, and *Suriname Folk-Lore* (New York: AMS Press, 1969, reprint of the 1936 edition) is a compendium of folkloric materials largely from coastal Suriname. For a vivid account of eighteenth-century Suriname society, including depictions of masters, slaves, and Maroons, see J.G. Stedman's *Narrative of an Expedition Against the Revolted Negroes of Surinam*, edited by R.A. Van Lier (Amherst: University of Massachusetts Press, 1972). A new critical edition of this work, including eighty full-page illustrations, many by William Blake, is now being prepared for publication. Edited by R. Price, this edition will be published in both paper and cloth by the University of Minnesota Press in 1982.

In 1974 we originated our epoch-making Galapagos Islands Thrift Cruises, which for several years enabled many hundreds of budget-minded travelers who were interested in ecology, wildlife and photography to see these unique islands without luxurious trimmings but under expert guidance.

We now again offer a budget program which includes some of the highlights which make a visit to this remarkable archipelago such a renowned tourist attraction. We explore five of the islands in order to view sea lions, iguanas and a large variety of birds, such as the famous Darwin's finches, boobies, frigates and gulls.

Galapagos Islands Thrift Program™

APRIL 4 TO 14, 1982
JUNE 27 TO JULY 7, 1982
DECEMBER 26 TO JANUARY 5, 1983

Our program includes easy hikes on Santa Cruz to see tortoises roaming free and to the top of the dormant volcano at Sullivan Bay, and ample opportunities for swimming and snorkeling. It is ideal for young people and families with children and has been planned during periods of school and college vacations.

We do not claim that these programs are as comprehensive as our superb and unrivalled **Discover Galapagos** yacht cruises in August and October, 1982; but our meticulously supervised arrangements do provide you with a fascinating introduction to these wonderful islands—and at a third of the cost.

Each program is accompanied by one of our expert leaders and a naturalist guide who give informative talks and lead us in the field.

Before the week at the islands, we spend two days at the best hotel in Quito, Ecuador's lovely capital in the Andes.

Please send for the detailed brochure of these programs—we also specialize in expeditions to Greenland, Mount Kilimanjaro, the Himalayas and the Andes; wildlife safaris to see polar bears and seals in northern Canada and to Scotland, Borneo and Rajasthan; and archaeological tours to Peru, Morocco and Egypt.

Weather and Climate in Tibet (p. 64)

E.R. Reiter's *Jet Streams* (Garden City: Doubleday and Co., Inc., 1967) is the first popular survey of this phenomenon. Beginning with a chapter on the discovery of jet streams, Reiter then explores how they are formed; how they move, are measured, and analyzed; and what effect they can have on weather and climate. Reiter also gives an excellent survey of the basic methods of meteorological investigation. "Rapid Rivers of Air," by E.R. Reiter (*Natural History*, March 1975, pp. 46–51), reviews the effects of jet streams on weather, climate, agriculture, and aviation (see that issue's "Additional Reading," p. 84, for four more references). H.H. Lamb's two-volume *Climate: Present, Past and Future* (London: Methuen and Co., Ltd., 1972) is an essential, authoritative reference work on climate fundamentals and history. This exhaustive study also discusses how to approach such problems as seasonal forecasting and advising on future climatic trends. Part one has 613 pages; part two has 835. The January 1981 issue of the *Bulletin of the American Meteorological Society* contains six articles by scientists who participated in an excursion by jeep across Tibet, organized by Academia Sinica and the Chinese government (pp. 4–36). The articles deal with local and regional meteorological and climatological problems in Tibet. S. Han's *Lhasa, the Open City* (London: Jonathan Cape, Ltd., 1977) is an anecdotal, conversational account of the changes, brought about by the diminished role of the religious elite and the increased role of the former serf class, that occurred in Tibet from 1950 to the present day. Han describes the effects of Chinese Communist influence, which she considers to be especially important and presents in a positive light. "Tibet-in-Exile: Triumph of a People," by J. Avedon, with photographs by E. Haas and D. Mehta (*GEO*, May 1981, pp. 84–110), is about the 85,000 Tibetans who, after a violent, unsuccessful uprising in 1959 against Chinese domination, fled to India with their leader, the Dalai Lama, and created a nation-in-exile.

Rita Campon

Erratum: The caption on page 46 of our August issue incorrectly identifies the avocet (top photo) as engaging in a distraction display, when it is, in fact, performing a two-wing stretch display. This behavior often precedes flight from a disturbance.

Darwin's Creatures

by Stephen Jay Gould

THE ZOOLOGY OF THE VOYAGE OF H.M.S. BEAGLE, edited by Charles Darwin. *Nova Pacifica Publishing Co. (P.O. Box 11106, Wellington, New Zealand), Facsimile reprint, 3 vols., $795.00 (including freight).*

Charles Darwin was not a city boy. He grew up in the countryside, attended Cambridge University, and of course, spent five years at sea aboard the *Beagle*. Yet Darwin chose London for his first independent home and lived there for several years, beginning as a bachelor and ending as the young husband of Emma Wedgwood. He claimed a deep antipathy for his new home in a letter to the Reverend Leonard Jenyns in 1837: "This London is a vile smoky place, where a man loses a great part of the best enjoyments in life. But I see no chance of escaping, even for a week, from this prison for a long time to come." If Darwin disliked London so much, what was he doing there?

The answer to this question requires that we abandon the usual image of Darwin, fostered by the photographs of his old age, as a quiet, reclusive, self-effacing, sick (or at least hypochondriacal) man. In London, Darwin was an ambitious, driving, energetic youth just home from a five-year trip around the world. Darwin stayed in London for the same reason that many young people today live, with great reluctance, in New York: he was building his career, and the sources of power, cash, and intellectual influences were concentrated in England's version of the Big Apple.

In particular, Darwin was busy politicking for the proper scientific disposition of his *Beagle* specimens (and—why not, after all?—for the resultant prestige that would accrue to him). This young and untested man wanted to line up the finest taxonomists of his day to describe the varied animals he had collected; above all, he needed cash for a lavish and uniform publication. Indeed, he had written to Jenyns to advance his project and to procure his collaboration:

> It would be more satisfactory to myself to see the gleanings of my hands, after having passed through the brains of other naturalists, collected together in one work. . . . The whole scheme is at present merely floating in the air. . . . I apprehend the whole will be impracticable, without [*sic*, we would write "unless" today] Government will aid in engraving the plates, and this I fear is a mere chance, only I think I can put in a strong claim, and get myself well backed by the naturalists of this place.

(Mr. Jenyns, by the way, deserves our deepest gratitude for far more than describing the *Beagle's* fishes. He had made it all possible in the first place—by refusing Captain FitzRoy's invitation to sail on the *Beagle* and thus opening a job for a young fellow named Darwin.)

Darwin was charming, patient, persistent, and well connected; he succeeded in wringing £1,000 from the Lords

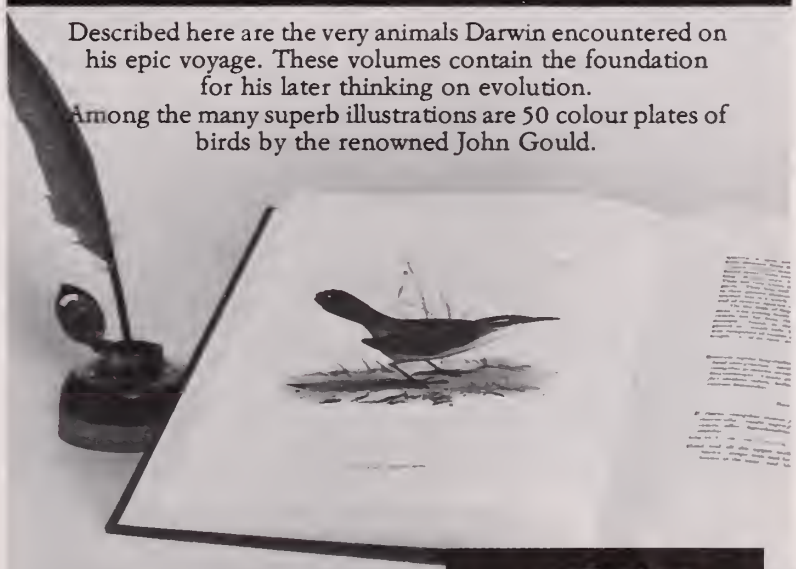
Commissioners of Her Majesty's Treasury. *The Zoology of the Voyage of H.M.S. Beagle* appeared in nineteen fascicles (reprinted as three volumes) between 1838 and 1843. England's finest taxonomists described Darwin's specimens—Richard Owen for the fossil mammals, G.R. Waterhouse for the living mammals, John Gould (no relation) for the birds, the Reverend Mr. Jenyns for the fishes, and Thomas Bell for amphibians and reptiles (invertebrates, apparently, didn't count and were described in periodicals or merely allocated to collections). The mammals and birds are illustrated with beautiful color plates, but Her Majesty's munificence must not have extended to "lower" creatures, for the reptiles, amphibians, and fishes appear in dull black-and-white.

The three-volume *Zoology of the Voyage of H.M.S. Beagle* is by far the rarest of all Darwiniana. Its initial printing was small, and it was never reissued. It occupies the stratosphere of antiquarian book catalogs; the last time I looked wistfully at a price, it had just entered five figures—yes, Virginia, for a book! We must therefore rejoice that New Zealand's Nova Pacifica Publishing Company has issued the first facsimile of this precious work—even though joy will remain abstract for all but a few, as a high three-digit price will not generate queues in local bookstores. Still, in a world awash in mediocrity, one can only praise a job so beautifully and lovingly done. The clarity of reproduction, including the rich color of the plates, is stunning, and the volumes are bound in cloth and leather "to a standard almost certainly higher than that of the original" (to quote from the appropriately immodest publisher's note). Thus, we can touch, smell, and feel in this reprint a bit of the finest workmanship from the great age of publication in descriptive natural history.



But the *Beagle Zoology* holds far more than a mere antiquarian or aesthetic interest. First of all, it contains descriptions of formidable specimens

A limited number only available

CHARLES DARWIN
THE ZOOLOGY OF THE VOYAGE OF H.M.S. BEAGLE

A three volume, facsimile reprint in a limited world edition of 750 copies.

Described here are the very animals Darwin encountered on his epic voyage. These volumes contain the foundation for his later thinking on evolution.
Among the many superb illustrations are 50 colour plates of birds by the renowned John Gould.

A unique combination of artistic, scientific and collectable value.

Sumptuously produced in 3 volumes. Bound in genuine leather and linen. 1096 pages, (12½" x 9¾"), containing numerous B/W and colour plates. Marbled endpapers.

PRICE US $795.00
Price includes packaging, airfreight and insurance.
American Express, Diners Club and Visa welcome.

by formidable people. In 1837 Darwin had written in his notebook: "In July opened first notebook on Transmutation of Species. Had been greatly struck from about the month of previous March on character of South American fossils, and species on Galapagos Archipelago. These facts (especially latter), origin of all my views." The *Beagle Zoology* contains formal descriptions of all these specimens—the giant fossil mammals by Richard Owen, the greatest paleontologist of nineteenth-century Britain; Darwin's finches by John Gould, England's premier ornithologist.

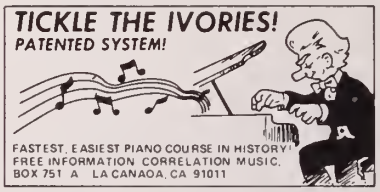
Secondly, the *Beagle Zoology* contains much more of Darwin than I and most historians realized (most of us, after all, never had the opportunity to see a copy of the work before this reprint, and we acted on hearsay and supposition). I knew that Darwin had been an active entrepreneur and had, of course, collected all the specimens, but I thought that very little of his own words or ideas were represented in the volumes. Not at all. Darwin wrote the geological section of Owen's monograph and a geographical introduction to Waterhouse's work. Almost half of Waterhouse's text contains verbatim transcriptions of Darwin's field observations on the habits and distribution of the animals he collected. John Gould described all the birds in the formal Latin then favored in taxonomic work (long lists of characters, all in the ablative), but he left for Australia before finishing the work. Darwin therefore wrote or edited most of the text and again provided long commentaries on his field observations.

We learn much about Darwin as a person and can only admire his honesty and enthusiasm. He revels in the abundance of giant vertebrate fossils when writing that "any line whatever drawn across the Pampas would probably cross the skeleton of some extinct animal." He faces his own shortcomings and inexperience in admitting that he had not appreciated the significance of his finches when in the Galápagos. (He had not even recognized them as close relatives or realized that many species were confined to individual islands. In fact, Gould's taxonomy—published here—first revealed the tale that Darwin would later exploit; he had not "seen" evolution in action while he visited the Galápagos.) "Unfortunately," Darwin writes, "I did not suspect this fact until it was too late to distinguish the specimens from the different islands

For the fifth year, we invite adventurous travelers to join us on a unique travel experience:

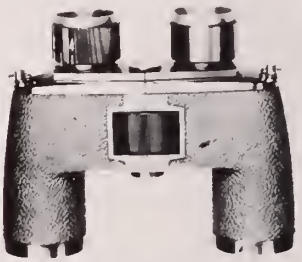
The Snows of Kilimanjaro

FEBRUARY 5 TO 22, 1982



Our expedition begins with a wildlife safari to Ngorongoro Crater, the Serengeti Plains and Lake Manyara, where we also undertake hikes to prepare us for the ascent of Africa's highest mountain, crowned with its permanent icecap.

In order to make the climb not only memorable but enjoyable, we allow plenty of time for resting at huts and camps to become used to the high altitude.



Detailed brochure of the expedition and a copy of our newsletter which lists all our fascinating travel programs, available from:

in the group, but from the collection made for Captain FitzRoy, I have been able in some small measure to rectify this omission." (FitzRoy had upstaged Darwin by labeling his specimens more completely.) In another passage, Darwin tells of stalking the petise, a small rhea previously unknown to science. But when a member of the *Beagle* crew finally shot one, Darwin didn't recognize what he had and ate his new species: "I looked at it, and from most unfortunately forgetting at the moment the whole subject of the Petises, thought it was a two-third grown one of the common sort. The bird was skinned and cooked before my memory returned. But the head, neck, legs, wings, many of the larger feathers, and a large part of the skin had been preserved."

More importantly, numerous passages scattered throughout the work give us important insight into the characteristic—and often quite individualistic and unusual—modes of thought that would later foster Darwin's evolutionary theory. Thus, the *Beagle Zoology* will also provide new information for Darwin scholars in the most vital area of all, especially important because so few historians have ever seen these passages. Consider just a few examples:

1. Darwin writes in his geological introduction to Owen's monograph: "In this part of South America there is reason to believe that the movements of the land have been so regular, that the period of its elevation may be taken as an element in considering the age of any deposit." In other words, upward motion by earthquakes, averaged over time, has been sufficiently uniform in rate that the height of a stratum above sea level will indicate its age. Now what Darwin actually saw in South America was the cataclysmic devastation wrought by local earthquakes. Yet he chose to focus his attention on the potential smoothing out of local catastrophes over long stretches of time to yield uniform average rates, rather than on the more literal extrapolation of local terror to a catastrophic theory of earth history. Here we clearly see the influence of Lyell (who treated earthquakes and volcanoes in the same way) and his so-called uniformitarian approach, an essential ingredient of Darwin's developing gradualism. Aside from natural selection itself, gradualism became the most pervasive and controlling aspect of Darwin's world view.

2. Discussing the unusual habits of the rhea, Darwin states that females lay eggs in several nests and that males then incubate them. In wondering how such a system began, he writes: "It is evident that there must at first be some degree of association, between at least two females; otherwise the eggs would remain scattered at distances far too great to allow of the male collecting them into one nest." Here Darwin uses a primary style of evolutionary thinking: faced with an "odd" adaptation, one must discover (or at least postulate) intermediary stages bridging the gap between ordinary ancestor and peculiar descendant. In thinking about how rheas developed their unusual system, Darwin neither invokes God's wisdom in design nor waxes eloquent about adaptive value. Already, he asks the evolutionist's historical question: How did such a system arise from more ordinary avian conditions? He argues for physical continuity (or evolution, if you will) by suggesting a rudimentary incipient state of loose association between females.
3. Darwin claims that the frigate bird "never touches the water with its wings, or even with its feet." Yet, its feet are webbed, and Darwin writes: "It appears that the deeply indented web between its toes is of no more use to it, than are the shrivelled wings beneath the wingcases of some coleopterous beetles." In Waterhouse's monograph, Darwin discusses the tucutuco, a burrowing rodent with apparently well-developed eyes, yet often found blind. Darwin writes: "Considering the subterranean habits of the Tucutuco, the blindness, though so frequent, cannot be a very serious evil; yet it appears strange that any animal should possess an organ constantly subject to injury."

   In both these examples, Darwin faces directly and wonders powerfully about the primary category of evidence for the fact of evolution: structures now useless (perhaps even marginally harmful) that "make sense" only as the retained product of a previous history (as water bird or terrestrial rodent).
4. In discussing the rats of Ascension Island, Darwin notes that animals from the mountain summit are black and glossy while those on the sea beach are browner. He suspects that these differences have arisen by local modification (a reasonable view, even for a creationist who would not deny, after all, the common sources of dog and cattle breeds). But Darwin then makes the crucial evolutionist's step of extrapolating local differentiation to cases of change at larger scale. If these local races arise naturally, then Ascension rats (designated by Waterhouse as a new species!) may only represent a "strongly marked variety" of ordinary rat "brought, by some ship, from some unknown quarter of the world." Two pages earlier, Darwin offers the same explanation for differences between common and Galápagos rats, where again Waterhouse had named a new species: "And if a very peculiar climate, a volcanic soil, and strange food, can together produce a race, or strongly marked variety, there is every probability of such change having taken place in this case."

Waterhouse interpreted these situations in a conventional, creationist manner. Differences between common and Galápagos or Ascension rats do not imply directed evolutionary change that might be extrapolated to events at larger scale. The common rat is a perfectly good, stable species; it merely has an uncommonly broad capacity for variation, as do all forms "which follow man in his peregrinations, and which, to a certain degree, are dependent upon man." "Like really domestic animals," Waterhouse states, these rats "are subject to a greater degree of variation than those species which hold themselves aloof." Darwin, on the other hand, is clearly wondering about the arbitrary boundary of species and the extrapolation of small into larger effects that transgress the limits of species and must record evolution.

The *Beagle,* by extension, must have had a wonderfully salutary effect upon those who dedicated themselves to its animals. In an age of limited life expectancy, Darwin himself died at 73. But the five monographers of *Beagle Zoology* did even better. John Gould died at 77; Waterhouse at 78. Owen and Bell lived to 88 and Jenyns reached 93. If these rewards were insufficient, we may rejoice that all these men now live again in the surrogate form of the most beautiful reprint in years.

Stephen Jay Gould, who writes "This View of Life" for Natural History, *teaches biology, geology, and the history of science at Harvard University.*

Portugal.
Everybody calls it Europe's greatest value.
We call it home.

They're right. Portugal is the greatest travel bargain in Europe. But it takes the special knowledge of the Portuguese to really get to know our special places and get the most enjoyment from them.

Starting with TAP Air Portugal, we make it easy to get to our beaches and castles, islands and mountains. We'll point out the places to see, things to do and where to sample a life that's loaded with pleasures, but not price tags.

Send in the coupon, we'll give you the details that make travel in and to Portugal the vacation experience of your dreams. At prices you can afford.

We're sure you'll love Portugal almost as much as we do.

Roots

The leaves, bark, and roots of the sassafras tree were believed to have medicinal properties

by Raymond Sokolov

Some years ago, I passed through New Orleans and the French West Indies investigating their Creole cuisines. Like the word *Creole* itself (derived from a Portuguese word meaning "create"), so-called Creole cooking was a complex notion, too complex, in fact, to talk about as a single phenomenon. In Louisiana, Creole food was one thing; in Martinique and Guadeloupe, it was a very different sort of adaptation of European food ideas to New World conditions, to products of this hemisphere, and to exotic methods and ingredients brought by black slaves from Africa. Certainly, no kitchen shelf in Fort de France could boast any of the green, powdered spice I had bought in New Orleans and stashed in my suitcase.

Distracted by such Antillean delicacies as *blaff,* the pungent fish stew, I forgot about the powder I was carrying and about the New Orleans gumbos it is frequently used to thicken. In the French West Indies, gumbo (in French, *gombo*) does not refer to a thick stew served over rice. *Gombo* is okra, reflecting the original name for that green pod (the source of my green powder) among the Kimbundu-speaking people transported from Angola by slavers. Our word *okra,* now the common name for *Hibiscus esculentus* in the United States, comes from another West African language, Tshi. "Gumbo" survived in our vernacular only as the name for the stew because in some recipes, okra, which turns ropy when cooked, is used to thicken the gumbo broth.

These intricacies were entirely lost on the United States Customs agent who extracted the bottle of green powder from my luggage at Kennedy Airport, beaming as only a Customs agent can beam when he is sure he has caught someone smuggling marijuana.

"What might this be?" he asked with a twinkle.

"Filé," I said pointing to the label.

"Oh, is that what they call it in French?"

"Yes, it means ropy, because it turns viscous and ropy when you cook with it. I bought it in New Orleans, where they use it in gumbos when they're not using okra for the same purpose."

The man took the bottle and went away to an office. Perhaps he gave it to a specially trained, marijuana-detecting bloodhound to sniff. I devoutly hope he tried to smoke some. Whatever method of analysis he used, it convinced him I was not trying to import a potent drug. He returned with the bottle and waved me back into the country.

Ironically, it was as a drug that filé first came to prominence in the world. Filé is prepared from the leaves of the sassafras tree, *Sassafras albidum,* whose aromatic bark and leaves and roots were highly sought after in the early days of exploration for their supposed medicinal properties. Gerard's *Herbal* (1597) asserted that "The roote of sassafras hath power to comfort the liver, and to dissolve oppilations, to comfort the weake and feeble stomacke, to cause a good appetite, to consume windiness, the chiefest cause of cruditie and indigestion, stay vomiting, and make sweete a stinking breath."

Gerard had much more to say about the beneficial qualities of this native American tree, which explorers found growing from southern Maine to Florida and west to the Mississippi. There seemed to be almost no human ill it would not cure, from plague to syphilis. Prices for this new-found panacea skyrocketed, and it rapidly became one of the chief early American exports to Europe. Annals of late-sixteenth-century exploration are full of excited accounts of discoveries of stands of sassafras. Walter Raleigh did his best to claim a monopoly on East Coast sassafras trade; in 1602, he confiscated a cargo brought back to England by an independent expedition to Cape Cod.

Indians had helped the men on that voyage harvest sassafras on Cuttyhunk Island off what is now New Bedford. They were already convinced of the curative powers of sassafras tea, and their British visitors were given concrete proof of its benefits when one of them took it to relieve a bellyache brought on "by eating the bellies of Dogfish, a very delicious meate."

Eventually, as Thoreau wrote, sassafras "lost its reputation." That is, it was no longer prescribed for infectious diseases, and the bottom fell out of the market. But even today, sassafras tea is sold in health-food stores. I recently brewed some and found it mild, appealingly red in color, and unremarkable in flavor. On the other hand, sassafras trees are quite remarkable. They reach a height of ninety feet in the Great Smoky Mountains and may live for 1,000 years. They produce three kinds of leaves, some lance shaped and entire, some three lobed, and some that are mittenlike with an oblique lobe on either side. Old trees have deeply furrowed, reddish brown bark, tinged with ash gray. The wood itself is reddish. Branches spread almost at right angles from the trunk and support smaller vertical branches.

Not only did the Indians teach the settlers to use the various parts of these magnificent trees for teas and gumbo thickening, but the settlers quickly began adapting sassafras to a recipe they had brought with them from Europe. With the bark, they brewed beer.

In colonial days, sassafras beer was only one of several "root" beers decocted from things growing in the woods. Birch beer, spruce beer, and sarsaparilla beer were all common early American beverages produced with roughly

the same simple techniques European farmers used to make beer from barley. But these tree-derived drinks had a negligible alcohol content, and they were thought to have medicinal, or tonic, properties. This is why even today in New England carbonated drinks are called tonics.

Modern manufacturers make their soft drinks fizz by forcing carbon dioxide into them under pressure. And the soft drinks we buy are truly soft because they are not fermented. Traditional root beer and the other sylvan beers were genuine beers, in the sense that their bubbles arose naturally as a byproduct of yeast fermentation.

A typical colonial recipe for root beer began with the making of a syrup. People boiled molasses and water, say one and a half gallons of molasses to five gallons of water, and then let the syrup cool for three hours. Into the syrup went a quarter-pound each of sarsaparilla root, bruised sassafras bark, and birch bark, which added a wintergreen flavor. Finally, our forefathers stirred in a cup of yeast and enough water to top off the vat at sixteen gallons.

The mixture was then allowed to ferment for twelve hours. Finally, when drawn off and strained, the root beer went into kegs or other sealed containers and continued to build up its fizz through secondary fermentation.

Usually the alcohol content of such old-time root beers remained below 2 percent, too low to be intoxicating. Some intrepid root brewers prolonged the initial fermentation so that the alcohol level rose as high as 10 percent, enough to make them feel silly. But under normal circumstances, root beer and the other forest beverages were low in alcohol and were classified as small beers. During Prohibition, root beer substituted for illegal malt-and-hops beer and was sold out of kegs in bars.

Some commercial breweries switched over to making root beer.

By then, it was no longer necessary to decoct flavorings from roots and barks as part of the actual brewing process. Chemists had learned to extract the essential oils of sassafras and wintergreen in the early nineteenth century. Later, they discovered methyl salicylate, a chemical also known as artificial oil of wintergreen.

Modern root beer manufacturers also dispense with molasses and resort to caramel coloring, which is sometimes souped up with soybean protein to make something known as foaming-type caramel. This is only one of several agents employed to give root beer a foamy head. Manufacturers also mix in a small amount of citric acid as a preservative that attacks bacteria responsible for cloudiness, syrupyness, and ropyness.

If all this organic chemistry makes you never want to drink root beer again, you can, without much trouble, hunt down a bottle of root beer extract at your local country store and brew your own. Or if that isn't natural enough, you could start from scratch, locating a sassafras log and stripping the bark. For an even more authentic and sophisticated flavor, extirpate a sarsaparilla shrub (*Smilax glauca*), dry the bitter roots and throw them into the caldron along with stems and leaves of the wintergreen (*Gaultheria procumbens*) or the young bark of the sweet birch (*Betula lenta*).

These other plants are not only traditional but entirely safe. Natural sassafras, however, is something you will probably want to avoid. Experiments conducted more than twenty years ago showed that the major constituent of oil of sassafras, a chemical called safrole, caused liver damage in dogs and cancer in rats and mice. The Food and Drug Administration banned safrole, which forced root beer manufacturers to forego the use of oil of sassafras altogether. One soft drink executive told me that the flavorings he now uses, such as oil of sweet birch, are not nearly as tasty as sassafras.

More recently, sassafras bark was banned for sale as sassafras tea unless it has been processed to make it safrole-free. Federal labeling requirements do not oblige manufacturers to state whether sassafras tea has been purified of safrole, but in any case, it seems pointless to buy the stuff. Either it is dangerous or it has had its principal flavoring element removed.

Only filé remains safe and available in its traditional form. Or at least that seems to be the case. Composed only of pulverized sassafras leaves, this spice either retains its potency after safrole removal or it does not naturally contain enough safrole to be banned. Without laboratory analysis, it is impossible to determine which is the case.

One thing is sure. Sassafras trees themselves are harmless as long as you don't chew them. Myself, when I need a panacea to ward off civilization's discontents, I sidle up to an *S. albidum* in the woods, break off a sprig, and inhale the aroma, following the example of the Onondaga Indians, who called sassafras twigs "smelling sticks."

Raymond Sokolov, a writer with an interest in the history and preparation of food, is editor of Book Digest.

Mrs. Pat Cashman's Turkey and Sausage Gumbo

- 1 turkey carcass (preferably from a smoked turkey), with a little meat left on
- ½ cup oil
- ½ cup flour
- 1½ large onions, peeled and chopped
- ½ green pepper, stemmed, seeded, and chopped
- 1 rib celery, chopped
- 1½ pounds smoked sausage (such as kielbasa), cut into 2½-inch rounds
- Salt
- Red and black pepper
- ¼ cup chopped parsley
- ¼ cup chopped scallion tops
- 2 cups rice, cooked
- 4–5 teaspoons filé

1. Cover carcass with water, bring to a boil, and simmer until meat begins to fall off bones, about one hour.
2. Remove carcass from broth and pick the meat off. Discard carcass and reserve meat and broth.
3. In a heavy iron pot, heat oil and stir flour into it. Reduce heat to low and stir mixture until it turns medium brown. This is a roux.
4. Add onion, pepper, and celery to roux. Cook until vegetables are tender, stirring constantly.
5. Add 2 to 3 quarts broth (add water to bring liquid up to the minimum 2 quarts, if necessary), sausage, and turkey meat. Bring to a boil, reduce heat and simmer for one hour.
6. Season gumbo to taste with salt and pepper. Stir in parsley and scallion tops. Cook 10 minutes longer.
7. To serve, put a portion of rice in a soup bowl (one per guest) and ladle gumbo over it.
8. Pass filé so that guests can thicken gumbo to their taste. Figure on approximately ½ teaspoon filé per guest.

Yield: 8–10 servings

Mrs. Vernon M. Ventress, Jr.'s Wild Duck, Sausage, and Oyster Gumbo

- 1 cup oil or bacon drippings
- 1 cup flour
- 4 onions, peeled and chopped
- 4 celery ribs, chopped
- 1 bell pepper, stemmed, seeded, and chopped
- 3 garlic cloves, minced
- ¼ cup parsley, chopped
- 1 pound smoked sausage (such as kielbasa), cut in ¼-inch rounds
- 4 wild ducks, cut up for frying
- 2 bay leaves
- 2 teaspoons salt
- Black pepper
- Cayenne pepper
- 3 pints oysters
- 2 cups rice, cooked
- Filé
- Chopped scallions

1. In a heavy iron pot, heat oil, stir in flour, cook over low heat, and stir constantly to make a brown roux.
2. Add onions, celery, bell pepper, garlic, and parsley and cook until tender, stirring constantly.
3. Add sausage and duck pieces. Cook until browned.
4. Stir in 4 quarts hot water, bay leaves, salt, and peppers. Bring to a boil, reduce heat and simmer, covered, for two hours or until duck is tender.
5. Add oysters and one-half of oyster liquor. Simmer uncovered for thirty minutes.
6. Put a portion of rice in each guest's bowl. Ladle gumbo over the rice and pass chopped scallions and filé as complements. Figure on about ½ teaspoon filé per guest.

Yield: 8 servings

INTRODUCING JETTA DIESEL: IT'S FOUR OF THE BEST MILEAGE CARS IN AMERICA.

Wait a minute.

How can we say that one car is four of the best mileage cars in America?

Easy.

Because the new Jetta Diesel is literally four Volkswagens in one.

When you fill it up, the Jetta Diesel's incredibly economical like our Rabbit Diesel, the best mileage car in America.

In fact, it gets an EPA estimated 41 mpg, 57 mpg highway estimate. (Use "estimated mpg" for comparisons. Your mileage may vary with weather, speed and trip length. Actual highway mileage will probably be less.)

When you load it up, the Jetta Diesel's spacious like our Dasher Diesel Wagon. With enough room and luxury so it won't cramp your style—or your passengers—on long trips.

57 hwy est 41 est mpg

And when you rev it up, the Jetta Diesel handles a lot like our sporty Convertible. Because, despite its economical diesel engine, it is a lot like our Convertible, thanks to its rack-and-pinion steering, front-wheel drive and 4-wheel independent suspension.

But perhaps the most impressive thing about the Jetta Diesel is that it's like a Jetta Diesel. Which means that it gives you sleek European styling, sophisticated German engineering and a trunk large enough to handle 8 suitcases.

So you see, having a Jetta Diesel really is like having four of the best mileage cars in America.

Except you only need one parking place.

ALL OUR BEST IDEAS IN ONE CAR. JETTA.

THE TASTE BEYOND 12-YEAR-OLD SCOTCH

Discover more.

Let your mature taste lead you from the finest premium Scotch on up to the most expensive 12-year-old Scotch in the world. The Glenlivet. The ultimate in Scotch.

Most premium Scotch is blended and depends on several whiskies for taste and smoothness.

Yet the unblended character of The Glenlivet is noble enough to stand alone. In this distinctive Scotch whisky you'll experience an exceptional smoothness and full-bodied richness, unmatched in all other premium Scotch.

Try the taste beyond premium Scotch.

The Glenlivet
Unchanged since 1824.

Authors

While working on the design of a solar building, **Lisa Heschong** became intrigued with how thermal qualities—warm, cool, humid, airy, radiant, cozy—could be used, like light, as an effective element of design. In her book *Thermal Delight in Architecture*, an excerpt from which introduces this special issue of *Natural History*, she has explored how people perceive hearths, gardens, and other places whose strong thermal qualities have special cultural associations. Heschong, who has a master's degree in architecture from the Massachusetts Institute of Technology, is a solar designer and a technical editor for *Solar Age* magazine.

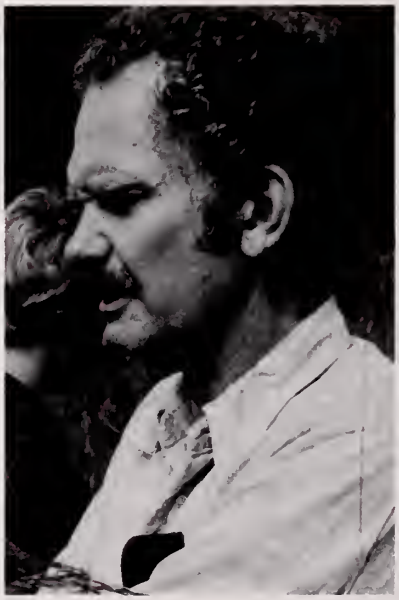
On the subject of being cold, **Fred Bruemmer** can be considered an expert. He writes that he has "lived with the Eskimos in Alaska, the Canadian north, and in Greenland during more than twenty years of fieldwork, often for as much as seven months of the year. Naturally, when one is cold and miserable, the subject of how to keep warm tends to be uppermost in one's mind." He has, consequently, studied the various means that the Eskimos have evolved to enable them to live in reasonable comfort in a land with an extremely uncomfortable climate. Bruemmer has recently returned from the High Arctic, where he spent the summer investigating the behavior of beluga whales.

Fascinated by the symbolism of fire in Siberian tribes, **Catherine Perlès** began to do research on the discovery and use of fire in prehistoric times. In 1977 she wrote a book on the subject, *Prêhistoire du feu*. An associate professor in the Department of Ethnology at the University of Paris at Nanterre, Perlès has done archeological fieldwork in both France and Greece. Her interests include stone-tool technology, prehistoric food processing, and the importance of diet changes in human evolutionary development.

Amanda Mayer Stinchecum's acquaintance with traditional Japanese attitudes and customs concerning how to keep warm stems from her experiences while living and traveling in Japan, as well as from her studies of Japanese art and literature. In particular, she has a longstanding interest in clothing and hand-produced textiles and in the relation between dress and forms of society. Holder of a Ph.D. in Japanese and comparative literature from Columbia University, Stinchecum is a free-lance journalist and museum consultant. She is now in Japan on a grant from New York's Metropolitan Museum of Art to research a book on Japanese "ikat" textiles—textiles in which the yarns are partly dyed according to a planned pattern before being woven.

© 1980 JULIUS WILE SONS & CO. IMPORTED FROM FRANCE 80 PROOF

A desire to explore the adaptations of animals to stressful environments has led **Cynthia Carey** to study quail in the California desert, toads in the high Rockies, and finches in the cold Michigan winter. Her present-day research includes the physiological and morphological adaptations of bird eggs to high altitudes. Carey is an assistant professor in the Department of Environmental, Population, and Organismic Biology at the University of Colorado.



Like coauthor Carey, **Richard L. Marsh** began to study birds' metabolic adaptations to cold climates while he was a graduate student at the University of Michigan. The project he worked on allowed him to "combine an interest in biochemistry with interests in adaptations of birds to their environments." Now a postdoctoral scholar at the University of California, Irvine, Marsh is continuing his research on muscle physiology and temperature regulation in birds and reptiles.

Lynn Rogers has been monitoring the life styles of black bears in northeastern Minnesota since 1969. A wildlife research biologist at the North Central Forest Experiment Station of the U.S.D.A. Forest Service in Saint Paul, he has paid particular attention to the behavior and the habitat requirements of the bears. Rogers is known as a zealot when it comes to bears. He thinks nothing of crawling into a hibernating bear's den and measuring the animal's heart beat by laying his head on its chest. He is also expert with the rectal thermometer. Such talents have led to more than one interesting moment, but he is as yet unscathed, albeit looking more bearlike every year.

Roger M. Knutson's observations of solar heating in plants were made over a period of years as he taught a course that took him and his students out among the spring flora of northeastern Iowa. A professor of biology at Luther College in Decorah, Iowa, Knutson is also studying the primary productivity of annual herbs, such as giant ragweed and nettle, that grow on flood plains. In an earlier article for *Natural History* ("Plants in Heat," March 1979), Knutson described his investigations into the regulation of heat production in eastern skunk cabbage.

William Dwight Billings first worked on the physiological ecology of high-mountain plants more than forty years ago in the Sierra Nevada. Since then, his research has taken him to mountains throughout the world—in Hawaii, New Zealand, Australia, and Lapland, and along the Rocky Mountains and the Andes from the Arctic to the Equator. Billings is James B. Duke Professor of Botany at Duke University, where he is currently studying the effects of increasing temperatures on the exchange of carbon dioxide among plants, soils, and microorganisms in tundra ecosystems.

hexa·photo·cybernetic

The Possibilities are Endless.

Stopped-Down: 90

Six-mode exposure control. System versatility. Newer electronics for wider applications.

The Canon A-1 is one of the world's most advanced automatic SLR cameras. Combining the finest in optical and mechanical engineering with the most sophisticated electronics, it's technology applied to give you the ultimate in creative control. At the touch of a button.

Depending on your subject, you can choose from six independent exposure modes to achieve the results you want:

1 Shutter-Priority: You select the shutter speed, to freeze the action and prevent camera shake or create an intentional blur. The A-1 automatically selects the appropriate lens opening.

2 Aperture-Priority: Control the area in focus by selecting the lens opening for the effect you want. The A-1 matches with the right speed.

3 Programmed: When you need to shoot fast, just focus. The A-1 will select *both speed and aperture* for great results.

4 Stopped-Down: For extreme close-up or specialized photography, a bellows, a microscope or almost anything can be attached to the A-1. It's still automatic.

5 Flash: Totally automatic flash photography, of course, with a wide variety of Canon Speedlites to choose from.

6 Manual: Yes. For those times when you absolutely want to do it all yourself. To experiment. To explore the possibilities.

There are over forty fine Canon lenses ranging from Fish Eye to Super Telephoto, plus accessories to meet every need. If you can't photograph your subject with a Canon A-1, it probably can't be photographed.

From the sophistication of its LED viewfinder display, to a ruggedness that allows up to five-frame-per-second motor drive, the Canon A-1 represents an incredible technology. At a price that makes owning one a definite possibility.

Canon® A-1

John V. E. Hansen is in charge of clothing, equipment, and materials research at the U.S. Army Natick Research and Development Laboratories in Natick, Massachusetts. The laboratory develops clothing and protective items that enhance the capability of U.S. soldiers to operate in all kinds of environments around the world. Hansen has a bachelor's degree in chemical engineering and has done graduate work in business administration. During the past nine years his duties have taken him from "Alaska to Arabia and from Ghana to Sweden."

Jane C. Nylander, curator of textiles and ceramics at Old Sturbridge Village, Massachusetts, has been reading early New Englanders' diaries and letters for fifteen years. From these and other literary sources she has gained a knowledge of the past that enhances the accuracy of historic house restoration and interpretation. A graduate of Brown University and the University of Delaware, Nylander is at present researching the textiles of eighteenth- and nineteenth-century New England.

A meteorologist by profession, with a Sc.D. in the subject **Edwin Kessler** is a farmer, gardener, and apiarist in his free time. Director of the National Severe Storms Laboratory of the National Oceanic and Atmospheric Administration in Norman, Oklahoma, Kessler lives on a farm and commutes to work. His farm has cows, chickens, a garden, and an orchard. He also grows rice in a 734-square-foot paddy. "I have a nice view," Kessler says, "and in addition the night sky is dark and is excellent for star gazing."

Colin High was born in London and received his B.S. and Ph.D. in geography and earth science from the University of Bristol. He moved permanently to the United States in 1973 because, he says, "it's nice here." He is now an associate professor of engineering and environmental studies at the Resource Policy Center of the Thayer School of Engineering at Dartmouth College. The center conducts research on the public and private use of such natural resources as forests, water, and energy. High's house in New Hampshire is heated exclusively with wood. It does not have a fireplace but does have an efficient wood-burning stove.

SHOWN SMALLER THAN ACTUAL SIZE OF 7-1/2" IN DIAMETER

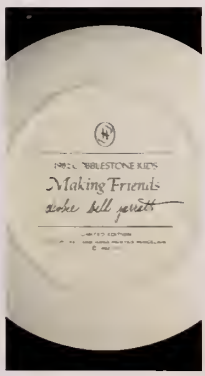
Advance subscription deadline: October 31, 1981.

Sculptured, hand-painted plates of fine porcelain have become a collecting tradition, mainly because of the Hummel series from Germany which portrays the children of the Alps at play.

Now to honor our own *American* children, Franklin Porcelain, America's foremost creator of collector plates, has created our *own* new series of collector plates, "The Cobblestone Kids." And we are pleased to announce the *very first* issue.

She's *Making Friends*. And she's charming. She's patting the cute little bunnies who hungrily eye the nice fat carrots she carries in her basket. Her rosy complexion and adorable golden curls make her one of the most delightful young ladies you're likely to meet anywhere. And you'll find her *only* on this beautiful new porcelain plate designed exclusively for Franklin Porcelain by Debbie Bell Jarratt, an artist with extraordinary ability to capture all the wonder and innocence of a child's world.

To further enhance this delightful plate, *Making Friends* is being crafted in *three dimensions*, with the design *sculptured* in all its rich detail, then *hand-painted* in 13 different colors, so that each plate is a completely separate and unique work of art. And despite the fact that new issues of Hummel plates are selling today for approximately $100, you may enter your order for *Making Friends* at the unusually attractive price of just $55, payable in two monthly installments of $27.50 each.



The all-important first issue—available only from Franklin Porcelain

In the established tradition of outstanding plates in fine porcelain, *Making Friends* will be made available in a limited edition, reserved exclusively for those who order from the collection of sculptuted porcelain plates before the end of 1982. The edition will then be permanently closed.

Significantly, too, *Making Friends* is the *first* issue in this important new series portraying the children of early America. And because it is the *first* in the series, it is the one likely to be most sought by collectors in the future.

Advance invitation valid only until October 31, 1981.

Making Friends will be created for Franklin Porcelain in Taiwan, home of some of the world's most talented porcelain craftsmen. No payment is required at this time. But to be sure of earliest shipment, you are urged to complete and return the Advance Order Form no later than October 31, 1981.

The backstamp of each plate (left) bears the name of the collection, the title of that individual plate, and the artist's signature.

OUR PLEDGE TO YOU: At Franklin Porcelain we take pride in our standards of design and craftsmanship. But we believe our efforts should be judged by the people we serve. You may therefore return *Making Friends* within 30 days, in its original condition, for your choice of replacement or refund.

© 1981 FP

ADVANCE ORDER FORM

Making Friends

Valid only until October 31, 1981.
Limit: One plate per collector.

Franklin Porcelain
Franklin Center, Pennsylvania 19091

Please enter my order for *Making Friends*, to be sculptured and hand-painted for me in fine porcelain. I need send no money at this time. I will be billed in two monthly payments of $27.50* for the plate, the first payment due prior to shipment.

*Plus my state sales tax

A Visit to Dayton

The site remains a pleasant, sleepy town, but the bestial cause of the Scopes trial stirs again

by Stephen Jay Gould

In his summation to the court, Clarence Darrow talked for three full days to save the lives of Nathan Leopold and Richard Loeb. Guilty they clearly were, of perhaps the most brutal and senseless murder of the 1920s. By arguing that they were victims of their upbringing, Darrow sought only to mitigate their personal responsibility and substitute a lifetime in jail for the noose. He won, as he usually did.

John Thomas Scopes, defendant in Darrow's next famous case, recalled his attorney's theory of human behavior in the opening lines of an autobiography published long after the famous "monkey trial" (*Center of the Storm*, Holt, Rinehart and Winston, 1967). "Clarence Darrow spent his life arguing—teaching, really—that a man is the sum of his heredity and his environment." The world may seem capricious, but events have their reasons, however complex. These reasons conspire to drive events forward; Leopold and Loeb were not free agents when they bludgeoned Bobby Franks and stuffed his body into a culvert, all to test the idea that a perfect crime might be committed by men of sufficient intelligence.

We wish to find reasons for the manifest senselessness that surrounds us. But deterministic theories, such as Darrow's, leave out the genuine randomness of our world, a chanciness that gives meaning to the old concept of human free will. Many events, although they move forward with accelerating inevitability after their inception, begin as a concatenation of staggering improbabilities. And so we all began, as one sperm among billions vying for entry; a microsecond later, I might have been the Stephanie my mother wanted.

The Scopes trial in Dayton, Tennessee, occurred as the outcome of accumulated improbability. The Butler Act, passed by the Tennessee legislature and signed by Gov. Austin Peay on March 21, 1925, declared it "unlawful for any teacher in any of the Universities, Normals and all other public schools of the state—which are supported in whole or in part by the public school funds of the State, to teach any theory that denies the story of the Divine Creation of man as taught in the Bible, and to teach instead that man has descended from a lower order of animals." The bill could have been beaten with little trouble had the opposition bothered to organize and lobby (as they had the previous year in Kentucky, when a similar bill in similar circumstances went down to easy defeat). The senate passed it with no enthusiasm, assuming a gubernatorial veto. One member said of Mr. Butler: "The gentleman from Macon wanted a bill passed; he had not had much during the session and this did not amount to a row of pins; let him have it." But Peay, admitting the bill's absurdity and protesting that the legislature should have saved him from embarrassment by defeating it, signed the act as an innocuous statement of Christian principles: "After a careful examination," wrote Peay, "I can find nothing of consequence in the books now being taught in our schools with which this bill will interfere in the slightest manner. Therefore it will not put our teachers in any jeopardy. Probably the law will never be applied. . . . Nobody believes that it is going to be an active statute." (See Ray Ginger's *Six Days or Forever?* Beacon Press, 1958, reprinted in paperback by Oxford University Press, 1974, for a fine account of the legislative debate.)

If the bill itself was improbable, Scopes's test of it was even more unlikely. The American Civil Liberties Union (ACLU) offered to supply council and provide legal costs for any teacher willing to challenge the act by courting an arrest for teaching evolution. The test was set for the favorable urban setting of Chattanooga, but plans fell through. Scopes didn't even teach biology in the small, inappropriate, fundamentalist town of Dayton, located forty miles north of Chattanooga. He had been hired as an athletic coach and physics teacher but had substituted in biology when the regular instructor (and principal of the school) fell ill. He had not actively taught evolution at all, but merely assigned the offending textbook pages as part of a review for an exam. When some town boosters decided that a test of the Butler Act might put Dayton on the map—none showed much interest in the intellectual issues—Scopes was available only by another quirk of fate. (They would not have asked the principal, an older, conservative family man, but they suspected that Scopes, a bachelor and free thinker, might go along.) The school year was over, and Scopes had intended to depart immediately for a summer with his family. But he stayed on because he had a date with "a beautiful blonde" at a forthcoming church social.

Scopes was playing tennis on a warm afternoon in May, when a small boy appeared with a message from "Doc" Robinson, the local pharmacist and owner of Dayton's social center, Robinsons' Drug Store. Scopes finished his game, for there is no urgency in Dayton, and then ambled on down to Robinsons',

To introduce you to a unique new series of animal books for children, we'd like to give you a

FREE BOOK.

These new animal books are so beautiful and informative that you must see them for yourself to fully appreciate them! That's why we want to send you the first book in the series *free of charge* . . .

As you (and your children) turn the pages of your free book, we think you'll be astonished by the sheer wealth of fascinating facts—and the beautiful way in which they are presented. Page after page, you'll see some of the finest animal photographs ever taken. You'll enjoy wonderful paintings especially created for ZOOBOOKS® by some of the finest nature artists in the world. And most important, you'll see for yourself how your children will love these books!

When you've finished looking over the free book, it's very likely that you will want your children to have further books in the ZOOBOOKS® series—and that's why we've devised a special arrangement that will make it possible for you to acquire these books **for only $1 per book.**

When we send your free book to you, we will also enter a special one-year trial subscription to ZOOBOOKS® in your name. You will then be eligible to receive 12 magazine-size books (8½″ × 11″) for only $12—a different book every month for 12 months. **This does not obligate you in any way.** If you are not completely satisfied with the sample book, simply cancel the subscription *and you owe nothing*. The free book is yours to keep, either way.

GORGEOUS ORIGINAL ILLUSTRATIONS

EXCITING NEW WAYS TO LEARN.

SCIENTIFIC FACTS MADE EASY.

PRINTED IN BEAUTIFUL COLOR.

The free book you will receive** is a superb introduction to the Great Apes (gorillas, chimpanzees, and orangutans) and the Lesser Apes (gibbons and siamangs). It's packed with striking photos and paintings showing how apes live, and an easy-to-read text tells why these incredible animals behave as they do. It's a stunningly beautiful book—**and it's yours without obligation of any kind!

OTHER BOOKS YOU WILL BE ELIGIBLE TO RECEIVE IN THE FUTURE (AS PART OF A SUBSCRIPTION) INCLUDE BIG CATS, BIRDS OF PREY, ELEPHANTS, BABY ANIMALS, SNAKES, BEARS, WILD HORSES, WHALES, AND ENDANGERED SPECIES.

Photographs by Deborah L. Gould

The Scopes trial was planned in Robinsons' Drug Store, which moved to its present location in 1928.

where he found Dayton's leading citizens crowded around a table, sipping Coke and arguing about the Butler Act. Within a few minutes, Scopes had offered himself as the sacrificial lamb. From that point, events accelerated and began to run along a predictable track. William Jennings Bryan, who had stirred millions with his "Cross of Gold" speech and almost become president as a result, was passing his declining years as a fundamentalist stumper—"a tinpot pope in the Coca-Cola belt," as H.L. Mencken remarked. He volunteered his services for the prosecution, and Clarence Darrow responded in kind for the defense. The rest, as they say, is history. Of late, it has, alas, become current events as well.

Robinsons' Drug Store is still the social center of Dayton, although it moved in 1928 to its present location in the shadow of the Rhea County courthouse, where Scopes faced the wrath of Bryan's God. "Sonny" Robinson, Doc's boy, has run the store for decades, dispensing pills to the local citizenry and thoughts about Dayton's moment of fame to the pilgrims and gawkers who stop by to see where it all started. The little round table, with its wire-backed chairs, occupies a central place, as it did when Scopes, Doc Robinson, and George Rappelyea (who made the formal "arrest") laid their plans in May 1925. The walls are covered with pictures and other memorabilia, including Sonny Robinson's only personal memory of the trial: a photograph of a five-year old boy, sitting in a carriage and pouting because a chimpanzee had received the Coke he had expected. (The chimp was a prominent member in the motley entourage of camp followers, many of comparable intelligence, that descended upon Dayton during the trial, in search of ready cash rather than eternal enlightenment.)

I was visiting Robinsons' Drug Store in June, when a San Francisco paper called with a request for photos of present-day Dayton. Sonny Robinson, who claims to be a shy man, began a flurry of calls to exploit the moment. Up north in the big town, you wouldn't keep a man waiting, at least not without a request or an explanation: "Excuse me, I know you must be in a hurry, but would you mind, it won't be more than a few minutes. . . ." But it was 97° outside and cool in Sonny Robinson's store. And where would a man be going anyway? Half an hour later, his personages assembled, Sonny Robinson pulled out the famous table and brought three Cokes in some old-fashioned 5¢ glasses. I sat in the middle ("the biology professor from Harvard who just happened to walk in," as Robinson had told his callers). On one side sat Ted Mercer, president of Bryan College, the fundamentalist school begun as a legacy to the "Great Commoner's" last battle. On the other side sat Mr. Robinson, son of the man who had started it all around the same table fifty-six years before. The fundamentalist editor of the Dayton *Herald* snapped our pictures and we sipped our Cokes.

Dayton has remained a small and inconspicuous town. If you're coming from Knoxville via Decatur, you still have to cross the Tennessee River on a six-car ferry. The older houses are well kept, with four white pillars in front, the vernacular imitation of plantation style. (As a regional marker of the South, these pillars are architecture's equivalent of the dependable gastronomical

From the publisher of PARROTS OF THE WORLD and AUSTRALIAN PARROTS.

criterion: when the beverage simply labeled "tea" on the menu invariably comes iced.) H. L. Mencken, not known for words of praise, confessed (in surprise) his liking for Dayton:

> I had expected to find a squalid Southern village . . . with pigs rooting under the houses and the inhabitants full of hookworm and malaria. What I found was a country town full of charm and even beauty. . . .The houses are surrounded by pretty gardens, with cool green lawns and stately trees. . . . The stores carry good stocks and have a metropolitan air, especially the drug, book, magazine, sporting goods and soda-water emporium of the estimable Robinson.

Some things have changed, of course. Trailers now rooted to their turf and houses of undressed concrete block reflect the doubling of Dayton's population to nearly 4,000. The older certainties may have eroded somewhat. A banner headline in this week's Dayton *Herald* tells of a $200-million marijuana crop confiscated and destroyed in Rhea and neighboring Bledsoe counties. And a quarter gets you a condom—"sold for the prevention of disease only," of course—at vending machines in restrooms of local service stations. At least they can't blame evolution for this, as one evangelical minister did a few months back when he cited Darwin as primary supporter of the four "p's": prostitution, perversion, pornography, and permissiveness. They taught creationism in Dayton before John Scopes arrived, and they teach it today.

For all these muted changes, Dayton remains a two-street town, dwarfed at the crossroad by the Rhea County courthouse, a Renaissance Revival building of the 1890s seemingly too large by half for a small town in a small county. Yet even this courtroom failed in its moment of glory, as Judge Raulston, noting that the weight of humanity had opened cracks in the ceiling below, reconvened his court on the side lawn, where Darrow grilled Bryan alfresco. (It is a meaningless and tangential irony to be sure, but I thought I'd mention it: I don't know how Rhea County got its name. Rhea was the daughter of Uranus and the mother of Zeus. Her name also applies to the South American "ostrich." On the *Beagle* voyage, Darwin rediscovered a second species, the lesser, or Darwin's, rhea, living in a different part of South America. In one of his first evolutionary speculations, Darwin surmised that the spatial difference between these two rheas might be analogous to the temporal distinction between extinct species and their living relatives.)

The Scopes trial is surrounded by misconceptions, and their exposure provides as good a way as any for recounting the basic story. In the heroic version, John Scopes was persecuted, Darrow rose to Scopes's defense and smote the antediluvian Bryan, and the antievolution movement then dwindled or ground to at least a temporary halt. All three parts of this story are false.

For the first, we have already noted that Austin Peay and the legislators of Tennessee did not intend to enforce their law. In fact, Bryan himself had lobbied the legislature (unsuccessfully) with advice that the act prescribe no penalty at all for noncompliance. It was, after all, only a symbolic statement; any teeth in the act might lead to its upset on constitutional grounds. The ACLU advertised in Tennessee papers for a test case. George Rappelyea read their offer in the Chattanooga *Times* and moseyed on down to Robinsons' with his plan. Later, John Scopes remembered: "It was just a drugstore discussion that got past control." For once, the tale of outside (even Yankee) agitators tells at least a half-truth.

Bryan was vanquished and embarrassed during the trial, but not primarily by Darrow. The trial itself, with its foregone conclusion, was something of a bore. (Scopes *had* violated the law and the defense wanted a quick conviction for an advantageous move to a higher court.) It dragged on in interminable legal wrangling and had only two moments of high drama. The first occurred during a legal argument about the admissibility of expert testimony. The defense had brought to Dayton an impressive array of men prominent both in evolutionary biology and Christian conviction. The prosecution urged that their testimony be excluded. The law plainly forbade the teaching of human evolution, and Scopes just as plainly had violated the law. The potential truth of evolution was not an issue. Judge Raulston agreed with the prosecution, and the assembled experts took to their typewriters instead. With benefit of a weekend recess to hone their statements, the experts produced some formidable documents. They were printed in newspapers throughout the country, and Judge Raulston finally did admit them into the printed record of the trial.

Bryan, who had sat in uncharacteristic silence for several days, used this procedural argument as a springboard for his prepared excoriation of evolu-

tion. In a grandiloquent speech clearly directed to his constituents (witnesses remarked that he stood with his back to the judge), Bryan virtually denied that humans were mammals and argued that the case of Messrs. Leopold and Loeb amply demonstrated that too much learning is a dangerous thing. The defense's rebuttal provided Bryan's first humiliation; for in this rural land, before the advent of television, no art commanded more respect than pure speechifying. And Bryan was just plain outspoken, outgestured, and outshouted—not by Darrow—but by another defense attorney, Dudley Field Malone, a prominent New York divorce lawyer and former subordinate to Bryan in the State Department (where Bryan had been secretary under Woodrow Wilson). H.L. Mencken wrote:

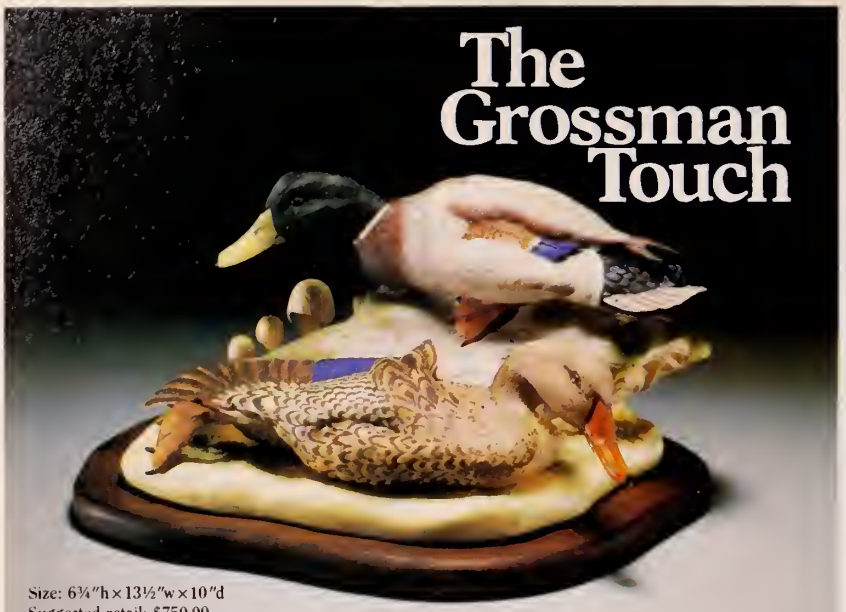
> I doubt that any louder speech has ever been heard in a court of law since the days of Gog and Magog. It roared out of the open windows like the sound of artillery practice, and alarmed the moonshiners and catamounts on distant peaks. . . . In brief, Malone was in good voice. It was a great day for Ireland. And for the defense. For Malone not only out-yelled Bryan, he also plainly out-generaled and out-argued him. . . . It conquered even the fundamentalists. At its end they gave it a tremendous cheer—a cheer at least four times as hearty as that given to Bryan. For these rustics delight in speechifying, and know when it is good. The devil's logic cannot fetch them, but they are not above taking a voluptuous pleasure in his lascivious phrases.

Nonetheless, Judge Raulston ruled against the defense and excluded expert testimony the next morning. It was Friday and all seemed over, including the shouting. Scopes would be convicted summarily on Monday morning; he had violated the law and Raulston's narrow construction of the case had excluded all other issues. Virtually all the journalists, including H.L. Mencken, left town to avoid both the lull of a weekend recess and the expected anticlimax to follow. Thus, when Darrow induced Bryan to take the stand as an expert witness on the Bible, he spoke to a depleted local crowd and a skeleton crew of journalists. The reconstruction of *Inherit the Wind* and other accounts dramatize what was only an afterthought.

It is not even clear why Raulston allowed Bryan to appear (since he had excluded experts of opposite persuasion). The other prosecuting attorneys tried to dissuade Bryan, and Raulston finally expunged the entire exchange from the record. Bryan viewed the occasion as a desperate attempt to recover from Malone's drubbing, but Darrow exposed him as a pompous fool. Still, the most famous moment of the exchange—when Bryan deserted strict fundamentalist tenets by admitting that the days of Genesis might have lasted far longer than twenty-four hours—was not, as legend has it, a reluctant admission drawn forth by Darrow's ruthless logic. Bryan offered this statement freely, as an initial response to a series of questions. He did not seem to appreciate that local fundamentalists would regard it as a betrayal, and the surrounding world as a fatal inconsistency.

Scopes's conviction was eventually quashed on a technicality. Judge Raulston had set the fine of $100 himself, but Tennessee law stated that all fines greater than $50 had to be recommended by the jury. With Bryan humiliated and the conviction quashed, the legend of victory for the defense arose, thus completing the heroic version. But the Scopes trial was a defeat (or a victory so Pyrrhic that it scarcely deserves the name) for several reasons. First, Bryan recouped by involuntarily taking the only option left for an imme-

...And suddenly it was as though I was next to him. I could make out every detail with incredible clarity and brilliance; the moist eyes, each feather stood out in startling detail. It was a moment I would never forget. I was glad I chose Nikons."



It's moments like these that make you glad you didn't settle for anything less than Nikon Binoculars. Their superb optics and uncompromising prism-lock construction are designed to give years of flawless performance even under the toughest conditions.

diate restoration of prestige: he died in Dayton a week after the trial ended. Ted Mercer's Bryan College, a thriving fundamentalist institution in Dayton, is his local legacy. Second, the quashing of Scopes's conviction was a bitter pill for the defense. Suddenly, there was no case left to appeal. All that effort down the tubes of a judge's $50 error.

The Butler Act remained on the books until its repeal in 1967. It was not enforced, but who can tell how many teachers muted or suppressed their views and how many children never learned one of the two or three most exciting and expansive ideas ever developed by scientists. In 1973, a "Genesis Bill" passed the senate of Tennessee 69 to 16. It legislated equal time for evolution and creation and required a disclaimer in all texts that any stated idea about "the origin and creation of man and his world . . . is not represented to be scientific fact." The Bible, however, was declared a reference work, not a text, and therefore exempt from the requirement for a printed disclaimer. This bill was declared unconstitutional a few years later.

Third, and sadly, any hopes that the issues of Scopes's trial had been banished to the region of nostalgic Americana have been swept aside by our current creationist resurgence—the climate that inspired my detour across the Tennessee River in June.

Late in his life, I came to know Kirtley Mather, emeritus professor of geology at Harvard, pillar of the Baptist church, lonely defender of academic freedom during the worst days of McCarthyism, and perhaps the finest man I have ever known. Kirtley was also a defense witness in Dayton. Each year, from the late 1960s to the mid 1970s, Kirtley gave a lecture to my class recalling his experiences at Dayton. It seemed a wonderful echo of times gone by, for Kirtley, in his late eighties, could still weave circles around the finest orators at Harvard. The lecture didn't change much from year to year. I viewed it first as a charming evocation, later as mildly related to current affairs, finally as a vital statement of pressing realities. This year, I will dust off the videotape and show it to my class as a disquisition on immediate dangers.

In 1965, John Scopes permitted himself this hope in retrospect:

> I believe that the Dayton trial marked the beginning of the decline of fundamentalism. . . . I feel that restrictive legislation on academic freedom is forever a thing of the

past, that religion and science may now address one another in an atmosphere of mutual respect and of a common quest for truth. I like to think that the Dayton trial had some part in bringing to birth this new era.

(Scopes, by the way, later went to the University of Chicago and became a geologist. He lived quietly in Shreveport, Louisiana, for most of his life, working, as do so many geologists, for the petroleum industry. This splendid man of quiet integrity refused to capitalize on his transient and accidental fame in any way. His silence betokened no crisis of confidence or any departure from the principles that led to his momentary renown. He simply chose to make his own way on his own merits.)

In 1981, Jerry Falwell has donned Bryan's mantle, and Scopes's hopes for a "new era" have been thwarted. Of course, we will not replay Scopes's drama in exactly the same way; we have advanced somewhere in fifty-six years. Evolution is now too strong to exclude entirely, and current proposals for legislation (including bills already passed in Arkansas and Louisiana) mandate "equal time" for evolution and for old-time religion masquerading under the self-contradictory title of "scientific creationism." But the similarities between 1925 and 1981 are more disconcerting than the differences are comforting.

As in 1925, creationists are not battling for religion. They have been disowned by leading churchmen of all persuasions, for they debase religion even more than they misconstrue science. They are a motley collection to be sure, but their core of practical support lies with the evangelical right, and creationism is a mere stalking horse or subsidiary issue in a political program that would ban abortion, erase the political and social gains of women by reducing the vital concept of the family to an outmoded paternalism, and reinstitute all the jingoism and distrust of learning that prepares a nation for demagoguery.

As in 1925, they use the same methods of willful misquotation to impart a "scientific" patina to creationism. I am now a major victim of these efforts because my views on rapid evolutionary bursts followed by long periods of stasis can be distorted to apparent support for creation by fiat and unchanging persistence of immutable types. (I do, however, take some comfort in the fact that creationists of the last generation were equally skillful and devious in twisting to their own purposes the statements of strict gradualists.) I was therefore amused (or soothed) to read that, in 1925, Bryan and company were exploiting in the same manner the forthright address that William Bateson delivered to the American Association for the Advancement of Science in 1922. Bateson had expressed his confidence in the fact of evolution, but had honestly admitted that, despite reigning pomposity and textbook pap, we knew rather little about the mechanisms of evolutionary change. Scopes's prosecutors had cited Bateson as "proof" that scientists had admitted the tenuousness of evolution itself. In his written affidavit to Judge Raulston, W.C. Curtis, a zoologist from the University of Missouri, submitted a letter from Bateson:

> I have looked through my Toronto address again. I see nothing in it which can be construed as expressing doubt as to the main fact of evolution. . . . I took occasion to call the attention of my colleagues to the loose thinking and unproven assumptions which pass current as to the actual processes of evolution. We do know that the plants and animals, including most certainly man, have been evolved from other and very different forms of life. As to the nature of this process of evolution, we have many conjectures but little positive knowledge.

The Creative Alternative From Soligor

Our 35-70mm Zoom Lens

By replacing the "standard" lens that came with your camera with one that sees wider and longer, you'll put pizazz in your pictures. Which is why you should look into our creative alternative—the Soligor 35-70mm zoom lens.

Use it to zoom in and crop right in the camera to give your portraits added impact. Or, zoom out to make your subject part of a wider scene for added interest, and to get the whole group in when you can't step back. The 35-70 lets you widen your view, or bring your subjects up close, so you can shoot as you've never shot before. Best of all, a surprisingly low price makes this creative lens the affordable alternative.

If you'd like to add excitement and impact to your photography, visit your nearest dealer and try our creative alternative—the Soligor 35-70mm zoom lens—on your Canon, Minolta, Pentax, Olympus, Nikon or other fine 35mm SLR camera. Or, write for full information.

Curtis also submitted a letter from Bryan's old boss Woodrow Wilson: "Of course, like every other man of intelligence and education, I do believe in organic evolution. It surprises me that at this late date such questions should be raised." Ronald Reagan, however, raised them on the stump before a fundamentalist crowd in Dallas.

I learned something in Dayton, or rather, remembered something I should never have forgotten, while sipping that 5¢ Coke around the original table in Robinsons' Drug Store. The enemy is not fundamentalism; it is intolerance. In this case, the intolerance is perverse since it masquerades under the "liberal" rhetoric of "equal time." But mistake it not. Creationists are trying to impose a specific religious view by legislative fiat upon teachers who reject it both by conscience and training. For all their talk about weighing both sides (a mere matter of political expediency), they would also substitute biblical authority for free scientific inquiry as a source of empirical knowledge.

All the commentators at Dayton, including the caustic H.L. Mencken himself, noted that the local people, although secure in their creationist beliefs, showed no intolerance or even discourtesy to the opposition. They feted Bryan when he arrived in town, and they provided a spread of equal size for Darrow. They applauded Malone on the merits of his speech. Mencken wrote:

> Nor is there any evidence in the town of that poisonous spirit which usually shows itself when Christian men gather to defend the great doctrine of their faith. I have heard absolutely no whisper that Scopes is in the pay of the Jesuits, or that the whisky trust is backing him, or that he is egged on by the Jews who manufacture lascivious moving pictures. On the contrary, the Evolutionists and the Anti-Evolutionists seem to be on the best of terms and it is hard in a group to distinguish one from the other.

Dayton has persevered in its geniality. I encountered warm disagreement with my evolutionary views, but I sensed no disrespect for my opinions and no inclination to demote me as a person because I disagreed with a favored belief. Geniality of this sort is widespread but, alas, so fragile. A few seeds of ugliness and intolerance can generate the cover

The twelve-day trial began inside Dayton's Rhea County courthouse but ended on a side lawn.

ORDER FORM

The American Horticultural Society
c/o The Franklin Library
Franklin Center, Pennsylvania 19091

Please send me *Houseplants,* Volume One of The Illustrated Encyclopedia of Gardening, absolutely FREE and without obligation. If you do not hear from me within 14 days, send me subsequent volumes for free examination at the rate of one every six weeks. Any I keep will be billed to me at $9.95* plus $1.45 postage, shipping and handling. There is no minimum number of books for me to purchase, and I am free to cancel my subscription at any time upon giving you thirty days' written notice.

Even if I decide not to continue with the Encyclopedia, *Houseplants* is mine to keep FREE.

B

The American Horticultural Society,
America's leading nonprofit center for gardening information,
invites you to

Take this illustrated, hardbound volume on Houseplants absolutely FREE

with no obligation to buy anything now or ever.

- **Practical information on over 400 different houseplants**
- **Show-how photographs, drawings and diagrams**
- **Step-by-step instructions on every phase of houseplant care**

Now, the experts of the American Horticultural Society will teach you what they've learned over the years about growing healthier and more beautiful houseplants. *And it won't cost you anything to find out.* Because the Society wants you to accept this large, hardbound, 144-page book on HOUSEPLANTS absolutely FREE—just to introduce you to their new Illustrated Encyclopedia of Gardening. But there's no obligation. You need never buy another book if you do not want to.

This authoritative volume gives you a *complete course* in houseplant care. You'll find out how to get the most out of the plants you now have. And when you want to pick a new one, there's a 9-page *Plant Selection Guide* to help you—listing 400 houseplants and how much light, water, humidity, etc., they need. Plus many illustrated charts, diagrams, drawings to show you how.

Now you can solve all your gardening problems

For more than 50 years, the American Horticultural Society has been helping gardeners solve their problems. Now they've put everything they know into this comprehensive Encyclopedia—all in straightforward, nontechnical language plus full-color photographs, step-by-step diagrams and special charts.

Each volume takes a single gardening subject and follows it through from beginning to end. FUNDAMENTALS OF GARDENING tells you what, when and how to plant for best results in *your* area of the country. ANNUALS gives you information on dozens of marigolds, 40 petunias, shows you colors, heights and best growing conditions for all your favorite annuals. ROSES includes a 14-page selection guide to help you choose the *right* roses, protect them in the winter, grow them indoors. PESTS AND DISEASES tells you the best way to control insects that attack your garden. VEGETABLES shows you how to *save money* by growing your family's favorites at a fraction of what they cost in the market.

And you'll learn about PERENNIALS, GROUND COVERS, LAWNS, PRUNING, BULBS and much more. So you'll have the most admired and healthiest garden in the neighborhood.

Start with your first volume Free

The American Horticultural Society is so sure these volumes will help solve your gardening problems that they will send you the first volume absolutely FREE. To obtain it, mail the attached card to The American Horticultural Society, c/o The Franklin Library, Franklin Center, Pa. 19091, which is producing the Encyclopedia for the Society. Please mail your card by October 31, 1981.

Photographs and other memorabilia of the famous trial still cover the walls of Robinsons' Drug Store.

for an entire field. We have nothing to fear from the vast majority of fundamentalists who, like many citizens of Dayton, live by a doctrine that is legitimately indigenous to their area. Rather, we must combat the few yahoos who exploit the fruits of poor education for ready cash and larger political ends.

It was easy to dismiss Bryan because he was such a fool in his political dotage. Mencken wrote in his sharpest prose:

> Once he had one leg in the White House and the nation trembled under his roars. Now he is a tinpot pope in the Coca-Cola belt and a brother to the forlorn pastors who bclabor half-wits in galvanized iron tabernacles behind the railroad yards. . . . It is a tragedy, indeed, to begin life as a hero and to end it as a buffoon.

Many current creationists seem equally pitiable in their pronouncements: can anyone take seriously a link between Darwinism and the four evil p's?

But Mencken also understood the dangers, for he wrote in his final lines:

> Let no one mistake it for comedy, farcical though it may be in all its details. It serves notice on the country that Neanderthal man is organizing in these forlorn backwaters of the land, led by a fanatic, rid of sense and devoid of conscience. Tennessee, challenging him too timorously and too late, now sees its courts converted into camp meetings and its Bill of Rights made a mock of by its sworn officers of the law.

Do movements of intolerance ever start in any other way, given our pervasive tendencies toward geniality? Do they not always begin in comedy and end, when successful, in carnage? Who did not regard Hitler as an object of pitiful derision after the beer hall putsch. And who can read the famous words of Protestant theologian Martin Niemöeller without a shudder:

> First the Nazis went after the Jews, but I wasn't a Jew, so I did not react. Then they went after the Catholics, but I wasn't a Catholic, so I didn't object. Then they went after the workers, so I didn't stand up. Then they went after the Protestant clergy and by then it was too late for anybody to stand up.

Clarence Darrow understood the roots of intolerance only too well when he said in Dayton:

> If today you can take a thing like evolution and make it a crime to teach it in the public schools, tomorrow you can make it a crime to teach it in the private schools and next year you can make it a crime to teach it to the hustings or in the church. At the next session you may ban books and the newspapers. . . . Ignorance and fanaticism are ever busy and need feeding. Always feeding and gloating for more. Today it is the public school teachers; tomorrow the private. The next day the preachers and the lecturers, the magazines, the books, the newspapers. After a while, Your Honor, it is the setting of man against man and creed against creed until with flying banners and beating drums we are marching backward to the glorious ages of the sixteenth century when bigots lighted fagots to burn the men who dared to bring any intelligence and enlightenment and culture to the human mind.

Ever the cynic, H.L. Mencken evaluated this impassioned plea: "The net effect of Clarence Darrow's great speech yesterday seems to be precisely the same as if he had bawled it up a rainspout in the interior of Afghanistan." We had better proclaim the same message today into a downspout that resonates across the nation.

Stephen Jay Gould teaches biology, geology, and the history of science at Harvard University.

THE SCIENCE–AND ART–OF

Keeping Warm

To survive the assaults of cold weather, the organisms that inhabit the earth rely on a wide variety of strategies: plants may drop their leaves; some animals fluff their feathers, while others hibernate; and human beings can choose to stoke the furnace, don a sweater, or even head for the nearest hot tub. This special issue of *Natural History* celebrates the diversity of ways in which life's battle against the cold is won.

Announcing...

The Ten Commandments
Plate Collection

- Important and beautiful original works of art by the distinguished artist, Mary Mayo.
- Lavishly hand-decorated with 240 square inches of pure 24kt gold.
- More gold by far than on any previous Danbury Mint plate collection.

Plates shown smaller than actual size of 9¼" in diameter.

Never in Danbury Mint history has gold been lavished to such an extraordinary degree on collector plates! And never before have collector plates honored a subject of greater grandeur or with more artistic majesty!

Here is a collection unlike any you've ever seen — combining with breathtaking beauty *three* of the treasures of our Western civilization!

For here is *gold* — the king of precious metals, prized for its rarity and universal value.

Here, too, is magnificent *original art in the grand tradition of the "old masters"* — art reminiscent of the masterpieces which adorn the world's great cathedrals, museums and houses of worship.

Finally, here is a majestic tribute to the foundation stone of our great religions and of our civilization itself — *The Ten Commandments*, plus two additional plates in honor of the two greatest teachers of those commandments, Moses and Jesus. (The Moses plate is shown at the bottom of this page.)

In all, the collection is a treasure that belongs in every home, *but only a fortunate few will have the opportunity to possess it!*

Hand-Decorated with a Lavish Border of 24kt Gold!

Each of these twelve collector plates will be richly hand-decorated with gleaming 24kt gold — more gold by far than any other plate collection in the history of the Danbury Mint!

From Biblical times to the present day, gold has been one of mankind's most treasured possessions and the ultimate standard of wealth. It is so prized because it is extraordinarily *beautiful* and exceedingly *rare*. Indeed, it is so scarce that all the gold mined since the beginning of time could fit into a single large room!

What's more, gold is *permanent* — it doesn't tarnish, corrode or deteriorate. A gold coin minted in the days when Moses received The Commandments would gleam as brightly today as it did then. Thus gold is known as the *eternal* metal, the medium artists and craftsmen throughout the ages have used to portray and honor the foremost figures and timeless doctrines of the world's great religions.

And now you can bring such golden artistic splendor into *your* home, where you can admire and enjoy it as often as you wish!

Original Works of Art in the Tradition of the Old Masters

For this exclusive private edition, the Danbury Mint has commissioned the distinguished artist, Mary Mayo, to create twelve original paintings expressly and exclusively for this collection.

As few other artists of our day, Mary Mayo has mastered her craft after years of studying the styles and techniques of the "old masters" — giants of classical art such as Rembrandt, Michelangelo and Raphael. Her canvases inspire a profound respect and admiration for such classic, timeless beauty!

Old World Craftsmanship Involving an Intricate Process

Like the original works of art, the production process to make these plates will respect time-honored traditions, employing the most expensive materials, highest standards of excellence, and patient hand-craftsmanship at every stage.

The plates will undergo a painstaking process of *five separate firings*: one to bake the china . . . a second to glaze it . . . a third to bond the radiant colors of the original art . . . a fourth to apply the beautiful "Old English" lettering along the rim identifying each plate . . . and, finally, a fifth to seal the luxurious gold border, which a skilled artisan has lavishly hand-painted onto each plate using a brush dipped in *pure liquid gold!*

A five firing process is exceptionally *rare* in the production of fine collector plates, and is a measure of the unsurpassed importance of this collection!

A Limited Edition Available only by Advance Reservation

The Ten Commandments Plate Collection will be available exclusively from the Danbury Mint. No plates will be sold separately and none will be made available in stores. The size of the U.S. edition will be forever limited to the exact number of collections reserved by the final deadline, December 31, 1981.

Convenient Acquisition Satisfaction Guaranteed

To reserve your *Ten Commandments Plate Collection*, simply complete the attached reservation application. There is no need to send payment now. Your twelve plates will be issued at the convenient rate of one every two months. You will be billed for each plate in two equal monthly payments of only $27.50 each.

If you receive any plate you are not completely satisfied with, you may return it upon receipt for replacement or refund. And you may discontinue your subscription at any time.

Act Promptly to Avoid Disappointment

This is truly a unique chance to assemble your own private gallery of classical art, richly embellished with an unprecedented *240 square inches of pure, 24kt gold!* To avoid disappointment, return the attached reservation application today!

RESERVATION APPLICATION H57

The Ten Commandments
Plate Collection

The Danbury Mint
47 Richards Avenue
Norwalk, Conn. 06856

Must be postmarked by December 31, 1981
Limit: One set per subscriber

Please accept my reservation application to **The Ten Commandments Plate Collection**. I understand this is a limited edition of twelve original works by artist Mary Mayo lavishly hand-decorated with 24kt gold.

I need send no money now. The collection will be issued at the rate of one plate every two months. I will pay for each plate as billed in two convenient monthly installments of $27.50 each. Any plate I am not completely satisfied with may be returned upon receipt for replacement or refund, and this subscription agreement may be cancelled by either party at any time.

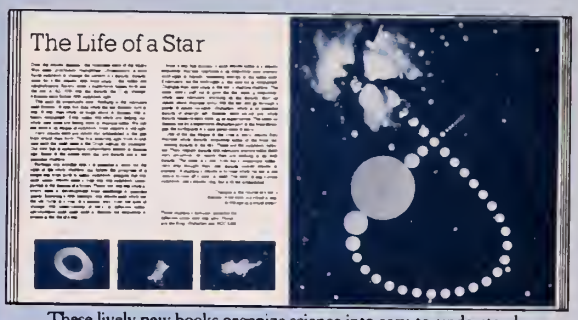
It's not just the kids who ask...we all like knowing more about the world around us. Now DISCOVERING brings you the answers in an exciting new way. Created in association with The American Museum of Natural History, it breaks science into manageable pieces and explains ideas simply, quickly, easily. After all, who knows more about making science fun than The American Museum of Natural History!

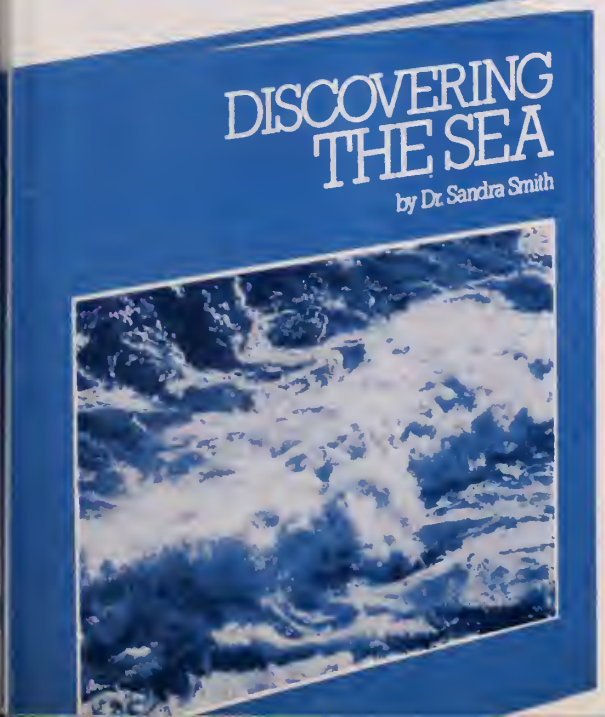
Your first volume DISCOVERING THE SEA takes you to earth's last frontier to explore its awesome geography...to learn how *tsunamis* or tidal waves can hit speeds of 450 mph...to see life flourishing in the lightless depths. You'll meet a creature bigger than any dinosaur, the great blue whale; it feeds on tiny krill—three tons a day! You'll see how beaches and deltas form...even how islands are created by nature's forces.



DISCOVERING THE SEA vividly demonstrates the way this new series can lead you through the wonders of today's science. As the series progresses, you will travel aboard the space shuttle *Columbia* to learn how its liquid- and solid-fuel systems produce its awesome lifting power. You'll explore other fascinating energy systems such as giant wind turbines and solar cells in space. You will venture into prehistory to look for the beginnings of life. You'll gain new understanding of the astonishing, tiny silicon chips that help computers speak...listen...draw pictures and design skyscrapers.

Here is a library for families with a curiosity about the universe and how it works. Books you'll refer to again and again. Colorful reading that will open your eyes to the wonders that surround you.

It's easy to discover the value of this new way of looking at science:



Enjoy DISCOVERING THE SEA for 10 days FREE. Then, if you wish, keep on DISCOVERING with your family. Succeeding volumes such as DISCOVERING ARCHAEOLOGY...ENERGY...ASTRONOMY...COMPUTERS...come one at a time. Each offers a rewarding look at an area of science at a remarkably modest price. See for yourself.

Unique format explains each concept quickly, completely

These lively new books organize science into easy-to-understand two-page units. This sensible approach lets you explore one complete idea at a time. It makes science easier to grasp ...and makes your reading fun and rewarding.

When they ask the tough questions, it's time for DISCOVERING

Explore your first volume DISCOVERING THE SEA for 10 days FREE

Thermal Necessity

Fat, feathers, and the Franklin stove provide the warmth needed to sustain life

by Lisa Heschong

Life exists within a small range of temperatures. It comes to a standstill as water freezes, and even the hardiest of bacteria are destroyed in boiling water. Each species of plant or animal has limits within which it can survive and a narrow range of temperatures within which it can successfully compete with other species. Ecologists studying certain lakes have discovered that a change of as little as two degrees Fahrenheit in the average water temperature will shift the dominant fish species to either bass or catfish, as one species becomes more efficient than the other. Thus, not only extremes but even subtle variations in temperature can be critical to an animal's survival.

The oceans, where early life evolved, provide a particularly stable thermal environment in which organisms can live without much thermal stress. Fish and other coldblooded sea creatures can function perfectly well at the temperature of their watery environment because the temperature of the ocean—and thus of their bodies—varies so little, and then only very gradually. The land, however, experiences great swings of temperature. On a daily and a yearly cycle, the surface of the earth is constantly heating up and cooling down. The ground, in turn, heats the air around it, driving the forces of weather that can so dramatically change thermal conditions over the course of a few hours. The organisms that moved out of the oceans and onto the land were those equipped to survive both climatic extremes and wide daily fluctuations.

The most direct way to cope with an adverse climate is to not be there when it gets too hot or too cold. Many of the simpler forms of life, such as bacteria, fungi, and yeast, suspend metabolism—essentially, stop living—when the temperature becomes inhospitable. Similarly, many plants and insects live only during the most favorable season; when that season ends, they die off, leaving behind seeds or eggs that will sprout or hatch when conditions improve again.

If an organism is to survive through a yearly cycle of seasons, however, it must possess some thermal "strategy" more sophisticated than simply not being there. One way of almost not being there, short of dying, is to be deciduous, an adaptation displayed by plants not only in snowy climates but in desert climates as well. By dropping all of their leaves, deciduous plants reduce their exposure to temperature extremes. Metabolic activity continues—but at a greatly reduced level and only in a protected core or in roots sheltered underground. Coldblooded animals and some mammals deal similarly with extreme cold: they hibernate, retreating to a place sheltered from temperature extremes. As body temperatures drop, metabolic rates are greatly reduced, enabling the animals to conserve energy for survival through the dormant period.

Animals have a great thermal advantage over plants because they can move about. Good travelers, such as birds and large herd mammals, can migrate between entire climatic zones so that they can avoid the worst thermal conditions of any particular region. On a smaller scale, animals can also move about to take advantage of the variations in climate—the "microclimates"—that occur within a given landscape. Snakes, sluggish from the night's cold, will crawl out of their holes to bask in the morning sun. With the sun's heat they can raise their body temperature considerably and begin to function effectively even though the morning air may still be quite cold.

Indeed, coldblooded animals have various techniques to maintain a steady body temperature in spite of swings in the external temperature. Terrestrial coldblooded animals, unlike fish, are not completely at the mercy of their environment. In addition to moving to the best thermal location, they can also vary their muscular activity to generate more heat within their bodies. On a cold day, butterflies vibrate their wings for several minutes to warm their muscles enough so that they can fly. Lizards can maintain a body temperature to within one degree of their optimum by combining two strategies: to warm up, they do "push-ups" on a sunny rock; to cool down, they retreat to a shady crevice and lie still.

It is the genius of the warmblooded animals, the birds and the mammals, that they evolved with a system for regulating their internal body temperature that takes full advantage of the heat naturally generated by their metabolism. In mammals, the muscular heat-generating technique of the coldblooded animals is refined so that a change in muscle tone can produce subtle gradations in the amount of body heat produced. Vibrations of the muscles have become an automatic shivering response—an emergency heat-generating measure. Over longer periods of time, many mammals can actually raise their basal metabolic rate to acclimate to cold.

Even more significant than the ability to change the rate of heat production is the capability of warmblooded animals to regulate the rate of heat flow away from the body. A variety of mechanisms allow these animals to release their excess heat into the environment in order

Some people feel...

"So what if I'm young. I've never had an accident or even gotten a ticket. Why should I pay the highest insurance rates?"

That's why we want you to know...

We understand how you feel. You've got a good driving record, and that's great. And you don't expect to have an accident. No one does. But the fact is that good drivers as well as bad have accidents. That's why insurance protection exists.

No one can predict which individual is going to have an accident. But we can predict the accident potential for groups of drivers who share similar characteristics. This is the only way possible to make auto insurance rates.

Insurance companies set their rates to reflect how often they have to pay claims of insured groups and how much those claims cost. This is done for each state and for each rating territory within the state.

Year after year, without exception, statistics show a consistent pattern: younger drivers have more accidents than older drivers. Young males have more accidents than young females. And young unmarried males have more accidents than young married men.

The fairest way to distribute accident costs is for each driver to pay an insurance rate that reflects as closely as possible the exposure to loss of his or her group. Of course, differences within the groups also are taken into account. Among them are the age and type of car and how the car is used (whether for business, pleasure or commuting).

But take heart. If you have a good driving record, you will pay less than others in your group who have been involved in serious accidents or who have been guilty of major traffic law violations. And, as you get older, the accident potential of your group will decline, and so will your rates.

We're working to keep insurance affordable.

This message presented by the **American Insurance Association,** 85 John Street. NY, NY 10038

to stay cool or to insulate themselves so thoroughly that their body heat is retained even in the coldest of places. For example, by panting or sweating, mammals create evaporative cooling, the dissipation of body heat through the vaporization of moisture. And one of the most important ways warmblooded animals regulate the flow of heat is through the circulation of the blood. In mammals and birds, the amount of blood flowing to the surface of their skin or even to entire extremities is controlled. Flushing the skin with blood serves to pump the heat of the inner body to the surface, where it can readily escape. Conversely, restricting the flow of blood to the surface serves to retain the blood's heat in an animal's inner core. In many species of waterfowl, virtually all blood flow to the legs can be cut off, reducing the heat lost to cold water.

Mammals and birds have also evolved a marvelous variety of ways to insulate their bodies. Fat, which occurs in other animals only as lumps that store food energy, is deployed in many mammals as a special insulating layer under the skin. The thickness of this layer varies in response to seasonal demands for protection against cold. Polar bears and huskies have such an effective layer of fat that they can comfortably sleep on ice. Fur and feathers are other forms of insulation, capable of exquisite variation in quality, quantity, and even color over the course of a year. Smooth and sleek and a bit oily in the summer, an animal's coat protects its skin from the sun's hot rays; in winter the downy undercoat is thicker and can be fluffed up to provide an even more effective insulation. The goose bumps that humans get when they are suddenly chilled is a remnant of response from the time when our ancestors still had fur to fluff. A coat of fur or feathers essentially traps a layer of air with its own climatic conditions: the animal's skin is not exposed to the prevailing climate but to the warmer air contained within the coat.

When, in the course of evolution, human beings lost the thick mammalian fur coat, they also lost its capabilities for thermal control. Our naked skin functions well in the hot, humid tropics but needs some assistance in other climates. The traditional clothing developed by various cultures often has extremely sophisticated thermal functions. The billowing white robes of the Arab reflect away the sun's radiation, while helping to fan air past the body and increase evaporative cooling. At the other extreme, the Eskimo's fur parka keeps in both body heat and water vapor from perspiration so that the Eskimo essentially lives within a semitropical environment.

Human beings, like other animals, also use shelter as a means for thermal control. Nest building is, in a way, an advanced version of choosing the most favorable microclimate. Animals that use a rock crevice or a hole in the earth to escape the cold (or heat) are indeed seeking out a favorable microclimate. Digging the hole a little deeper and adding a bit of shed fur for insulation are simple improvements. All animals start their nests by finding the best location, but only a few of the most talented nest builders—some birds, beavers, and *Homo sapiens*—can completely transform an environment to meet their needs. For example, the Anasazi Indians of the southwestern United States were remarkably clever in choosing sites for their cliff dwellings. They invariably chose locations shaded in the summer by an overhanging ledge of the cliff but exposed to full sun all winter long. With their backs to the cliff, the dwellings were protected from the winter winds and also took advantage of the thermal mass of the earth to moderate the temperature flux.

Buildings, even in the conventional ways they are constructed now, can be viewed as a way to modify a landscape to create more favorable microclimates. As soon as a simple square hut is built, at least six new microclimates are created: the south side warmed by a sunny wall; the north side in shade most of the time; the east side with its morning sun and perhaps protected from the prevailing breeze; the west side warmed in the afternoon but buffeted by the wind; the interior with its shelter from rain, wind, and sun; and the roof, raised above ground level and more exposed to the elements. A building increases the range of available thermal zones so that people can select the microclimate most suited to their thermal needs.

Vernacular building traditions all over the world display remarkably sophisticated adaptations. Primitive builders consistently used forms and materials that effectively moderated prevailing climatic conditions. For example, in the desert the characteristic problem is extremely high daytime temperatures coupled with uncomfortably low temperatures at night. The ideal building material would have a high heat capacity—to absorb solar radiation during the day and slowly radiate it back at night. Thus, buildings of adobe, mud and rubble masonry, and thick clay mortar on twig mesh are found in the American Southwest, the Middle East, and across Africa. A particularly ingenius response to climatic needs is seen in the Eskimo igloo. Using material of very low thermal capacity—dry snow—the Eskimo builds a small dome, a shape both resistant to wind and easily heated by a single oil lamp. A glaze of ice, which automatically forms on the inside surface, seals the structure and acts as extra insulation, along with furs that are draped against the wall. Clever use of the insulating qualities of snow is not unique to the human inhabitants of the Arctic. Many arctic animals bury their nests deep in the snow; protected from winds the animals' body heat can warm the enclosure. But the Eskimo has one transcendent advantage—the use of fire.

Fire offers enormous potential for affecting the thermal environment. Plants and the simpler animals are totally dependent upon the sun and weather to provide the heat necessary for their survival. Coldblooded animals make use of their own body heat to help keep themselves warm, and warmblooded animals are masters at regulating this internal source. Fire allows human beings a third mechanism, one independent of the fluctuations of climate and their own metabolism. With the control of fire, people can generate heat at will to warm themselves and their environment.

The most primitive dwelling was typically just a small round shelter with a fire pit at its center. In Europe, as late as the Middle Ages, it was still common practice to have an open fire in the center of a room with the smoke escaping through a hole in the roof gable. Such fireplaces were extremely inefficient, causing as many heating problems as they solved. Flames were more valued than embers, but large, open fires consumed great quantities of oxygen, pulling the cold outside air in through the cracks of the building as quickly as the heated air escaped through the roof hole. Since the air inside the dwelling would not stay heated, the only way to benefit from the fire's warmth was to sit directly in front of the flames.

About the end of the Middle Ages chimneys began to be used to channel off the smoke of a fire. Early chimneys were made of wood, but people soon

realized that a stone or brick chimney was not only safer but also absorbed heat from the fire and later radiated it back into the room. To take advantage of this form of heat storage, people began to build ever more massive masonry chimneys. In homes in northern Europe, these chimneys evolved into a huge central structure that might incorporate a number of fireplaces, ovens, and flues, with a sleeping loft on top where a bed could be kept deliciously warm.

As firewood became scarce, however, people looked for a heating system that would be more efficient than an open fire. At the end of the eighteenth century, the American-born physicist Count Rumford endeavored to make a science of fireplace efficiency, designing a fireplace that radiated a much greater percentage of its heat into the room. Benjamin Franklin had an even better idea, putting the fire in a metal box installed within the fireplace. His design included a separate air box through which fresh air could be circulated and heated, uncontaminated by the gases of combustion. Later manufacturers simplified the concept, moving the stove out into the middle of the room, where its heat could radiate in all directions. The Franklin stove was the "Model T" of the heating business, mass produced and the pride of households all over the country.

With the Franklin stove came the revolutionary idea that a fire could heat a house indirectly—by heating the air, which could then be circulated to keep people warm anywhere in the house. This idea initiated the changeover from a radiant to a convective system of heating. Improvements were made to extract more and more heat from the firebox, and the stove was transformed into a furnace. For the first time a building was seen as an enclosure for a bubble of warmed air, and attention began to be paid to making the enclosure more airtight. Merely blocking out the rain and wind was not sufficient in an air-heated house, for if a building still leaked air, pressure from the wind could drive all of the heated air to one side of the house and out through the walls.

In the nineteenth century, the new scientific understanding of the processes of convection and radiation brought a flurry of efforts to design the perfect furnace—safe, clean, efficient, and inexpensive. At first, natural convection, which depends on gravity, was most commonly used to move warmed air

Up until now you've been seeing less than what you paid for–30% to 50% less. Here at last is a mini that compensates for the distance between the eye and the eyepiece to give eyeglass wearers full field of view. Wearing glasses, you get 30% greater field of view than with the best of other minis–300 feet at 1,000 yards as against 174 feet at 1,000 yards.

Though a pygmy in size, it performs like a giant. With all the magnification, brilliance, clarity and contrast of its big brothers. Built to last a lifetime, it's guaranteed to last a lifetime.

through a house, but pressure differentials and temperature stratification tended to create a very uneven distribution of heat. Steam heat looked promising for a while because it solved the problem of moving heat from where the fuel burned to where the heat was actually wanted. The steam could be piped under its own pressure and then, on losing its heat, would condense back to water and return by gravity. Steam radiators, however, were noisy and excessively hot. With the development of small electric motors, heat distribution problems were more easily and comfortably solved. Small electric pumps could move warm water noiselessly through baseboard convectors, and electric fans could force warmed air to every corner of a building. In addition, these motors could be controlled with electric signals from thermostats so that a steady temperature could be automatically maintained.

By the early part of this century the technology of heating with mechanical systems had been worked out fairly well. But heating is only half of the climate-control problem and by far the easier half to solve. It is much simpler to generate and retain heat than to dispose of it. In hot, dry climates people have long depended on evaporation to dispose of unwanted heat, using systems of fountains, plants, and even permeable clay pots filled with water to cool and humidify the air. But in humid climates evaporation is greatly inhibited and radiational cooling to the night sky is also reduced. This made it nearly impossible to cool a place in hot, humid weather until the advent of air-conditioning technology—a revolutionary step in climate control.

About the turn of the century, Willis Carrier, an American engineer, hit upon a way to simultaneously dehumidify and cool air. He developed the somewhat paradoxical system of dehumidifying air by passing it through a spray of water. Based on the principle that cold air cannot hold as much absolute humidity as warm air, Carrier's system passed warm humid air through a spray of chilled water. In this way, the air was cooled and forced to lose its excess humidity, which would then condense on the surface of the water droplets in the spray. By choosing how cold to make the water spray, it was possible to control exactly how much humidity would be left in the air. The air could be reheated to a comfortable room temperature,

yielding air at precisely the temperature and relative humidity desired. With Carrier's discovery, for the first time all the elements of thermal control were available.

In recent years, standards for thermal comfort have been incorporated into many municipal and state building codes in the United States. Nowadays, there is an underlying assumption that the best thermal environment is one that need never be noticed, and that once an objectively "comfortable" thermal environment has been provided, all of our thermal needs will have been met. Our extremely sophisticated environmental control systems are all directed to this one end.

To maintain such unnatural uniformity, however, not only requires a great deal of effort and energy but also overlooks an important aspect of the way human beings experience a space. Such thermal qualities as warm, cool, humid, and airy and, in particular, the juxtaposition of these qualities provide a special source of comfort and even delight. We all love having our world full of colors—every color in the rainbow and then some. Even though studies have shown blue to be the most restful color, I doubt that anyone would put forth an argument for a monochromatic world. And yet a steady-state thermal environment is the prevailing standard for office buildings, schools, and homes across the United States.

The steady-state approach to the thermal environment assumes that any degree of thermal stress is undesirable, that people must be spared the effort and the distraction of adjusting to different conditions. And yet, in spite of the extra physiological effort required to adjust to thermal stimuli, people definitely seem to enjoy a range of temperatures. Indeed, they frequently seek out extreme thermal environments for recreation or vacations. This must explain in large part the love of the Finns for their saunas and the Japanese for their scalding hot baths. Americans flock to beaches in the summer to bake in the sun and travel great distances in the winter to ski on frosty mountaintops. People relish the very hotness or coldness of these places. There is far more richness in the thermal environment than just one zone of comfort. The thermal environment has the potential to provide us with sensual delights and cultural associations that should not be designed out of existence. □

Q. What is the new WEBSTER'S DELUXE UNABRIDGED DICTIONARY about?

A. It's about 2,300 pages and more than 4 inches thick!

For more than 40 years Webster's Unabridged Dictionary has served as an invaluable reference for students, teachers, businessmen, secretaries . . . and workers in all trades and professions. The reason is simple. Here is a dictionary that fills the need for accurate and full definitions, correct spellings and pronunciations, full etymologies, synonyms, as well as other general and specific information.

A large staff of lexicographers and linguists has painstakingly edited and updated each definition so that it is clear, accurate, and readily understood in all its senses. Many new entries have been added, including recent additions to the language in the natural and social sciences, the humanities and other specialized branches of human knowledge.

un à bridged′, *a.* not shortened; complete; specifically, designating a dictionary that has not been abridged from a larger work.
un aç cent′ed, *a.* not accented; specifically, in

The large, clear, legible type shown above (actual size) "makes this unabridged dictionary the most readable one in print."

. . . now own one of the finest reference books in the world at less than ⅓ of its originally published price.

DELUXE COLOR EDITION
Includes Thousands of Illustrations Along With a Complete Collection of Full-Color Maps of the World

Plus it contains these important supplements!

1. A Dictionary of Biography
2. A Dictionary of Geography
3. A Dictionary of Noted Names in Fiction, Mythology, Legend
4. A Dictionary of Foreign Words and Phrases
5. A Dictionary of Scripture Proper Names and Foreign Words
6. Abbreviations Commonly Used in Writing and Printing
7. Practical Business Mathematics
8. Forms of Address
9. Tables of Weights and Measures
10. Special Signs and Symbols
11. Presidents of the United States
12. Vice Presidents and Cabinet Officers of the United States
13. Declaration of Independence
14. Constitution of the United States
15. History of Canada
16. Charter of the United Nations
17. Air Distances between Principal Cities

Hearth and Home in the Old Stone Age

Lighting a fire was only one of the ways prehistoric humans kept warm

by Catherine Perlès

Early human populations did not, in most regions and periods, have to withstand a very cold climate, but numerous prehistoric hunter-gatherers did adapt to cold steppe and tundra environments, surviving the periodic onslaughts of the Ice Age glaciers. Archeological knowledge of the means of such adaptation is, however, still largely hypothetical. The remains of fur clothes, skin dwellings, and similar organic materials are rarely preserved, so the existence of such items usually can only be inferred from indirect evidence. And while fire leaves traces of calcination—powder and ash formed by the action of the heat—interpretation of these traces is still difficult. Burned bones or stones, ashes, and charcoal all attest to the use of fire but seldom tell us its purpose: hearths lit for heating or lighting a habitation or for grilling meat leave very similar traces.

Although the earliest stone and bone tools were made by humans living in Africa some 3 million years ago, the oldest evidence discovered of the use of fire comes from Europe (l'Escale and Terra Amata in France, Vertesszölös in Hungary) and Asia (Chou-k'ou-tien in China). The European sites are attributed to the second glacial period (500,000–400,000 years ago) while Chou-k'ou-tien dates from the warm interglacial period that followed. Several other Eurasian examples date from the third glacial period (200,000–100,000 years ago), whereas in Africa, evidence of fire seems to be of a much later date.

That the use of fire should appear first in northern regions and during relatively cold periods has often been taken as proof that fire was a prerequisite to the colonization of what was an inhospitable environment. According to this argument, early hominids (*Australopithecus* and *Homo habilis*) were confined to the ancestral African home because they lacked fire, while at a later stage, more evolved hominids (*Homo erectus*) were able to expand all over the world with the aid of fire. While it is true that all the oldest traces of fire can be attributed to *Homo erectus*, this does not necessarily establish a link between fire and the colonization of Eurasia. Fire, with its many applications, is just as useful in Africa as anywhere else, and it would be premature to conclude that it is not as ancient on that continent. Furthermore, the European climate during the second glaciation was not very cold, and the Vertesszölös hearths actually date from a warm interphase that occurred during the second glacial period. Most important, perhaps, is that an even larger number of Eurasian sites of the same antiquity, and sometimes older, show no trace of fire use, demonstrating that prehistoric humans could adapt to these colder environments without an artificial source of warmth.

In fact, the use of fire seems to have spread rather slowly in Europe and Asia. All throughout the Lower Paleolithic (from 3 million to 100,000 years ago), hearths and other remains of combustion are scarce; not until the Middle Paleolithic (from 100,000 to 35,000 years ago), does the use of fire become the rule rather than the exception. This change has often been interpreted as a major technological shift from the (unreliable) preservation of embers from natural sources to the systematic production of fire. Unfortunately, it is unlikely that we will ever be able to prove this hypothesis because the simplest fire-producing devices leave no specific traces in prehistoric sites.

Many technologically simple means to create fire have been feasible for several hundred thousand years. These primitive methods can be grouped into two categories: percussion between two stones and friction between two pieces of wood. Rapid friction between two sticks of wood will generate sufficient heat to kindle such flammable material as dry moss, tow (plant fibers), or sawdust. Friction can be produced manually by a sawing motion or by placing one stick of wood on another and twirling, or rotating, it between the palms of the hands. One method of speeding up rotation, and thus enhancing the efficiency of the fire drill, is to loop a leather strap or bowstring around the stick and draw it back and forth. Lighting a fire by striking two stones together is generally more difficult. If two pieces of flint are used, the tiny sparks produced must come immediately in contact with very flammable tow. It is easier to produce fire by striking flint against a "fire-stone" of iron mineral such as pyrite or chalcopyrite, both abundant in nature.

All such apparatuses for making fire are light and easy to carry, and their elements are easy to replace; equipped with them, prehistoric people could have produced fire wherever they were. But archeologists have little indication of when these possibilities were first exploited. Except in unusual circumstances, wood disappears when buried in the ground, so there is little hope of finding wooden fire drills or sticks. A few remains, such as a carbonized stick found at Krapina, in Yugoslavia, are not convincing evidence. Flints for starting fires must have been preserved, but we have not been able to distinguish them from other tools made of knapped, or chipped, stone. As for the pyrite fire-stones, the most ancient one recovered dates only from the Upper Paleolithic (35,000 to 12,000 years ago); these tools seem to be more abundant in later sites, such as the Mesolithic settlement of Star Carr in England (9,500 years ago).

We may never know when human beings learned how to produce fire, but this technological achievement may have had fewer implications than the discovery of the use of fire itself. From the very beginning, the acquisition of fire must have meant a new distribution of tasks within the prehistoric group. Some members may have specialized in maintaining the fire—important for symbolic as well as practical reasons—while others collected the necessary

fuel. And the custom of preparing and taking meals in common—a major source of cohesion and exchange in human groups—may date from when food could be cooked. Assuming that the burned bones found discarded in prehistoric dwelling sites are evidence of meat cooking, then cooking goes back to *Homo erectus* of Lower Paleolithic times. (One can also argue that the bones were only used as fuel. For example, in the absence of abundant wood, the mammoth hunters of central Europe and the Russian plain used mammoth bones as a primary fuel.)

An early example of how effectively fire could be used for heating can be found at the Lower Paleolithic site of le Lazaret, at Nice, where a hut was built about 150,000 years ago in a small cave overlooking the sea. The hut was made by leaning wood poles against the cave wall and covering them with animal skins, which were anchored to the ground by stones. Inside were two small hearths, which (if the hut was windproof) could have maintained the 500-cubic-foot interior at a temperature of 60° to 70°F while it was 25° outside. In general, a Paleolithic dwelling several meters in diameter had just one hearth.

In the cold Upper Paleolithic, prehistoric peoples apparently developed a technique for preserving as much heat as possible from the fireplace. Several sites of this period (notably in France, where Paleolithic hearths have recently been examined in detail) have yielded hearths that were either filled or covered with a dense layer of burned pebbles or angular stones (sandstone, granite, limestone, and so on). In some instances, it has been possible to prove that the stones were laid on burning embers and not removed afterward. A likely explanation is that the stones were meant to accumulate heat when the fire was at its maximum and to give it back slowly during the night or conserve it during a temporary absence. At the same time, the system would have allowed for the economizing of fuel, which may already have been a preoccupation in Paleolithic times. Each time such a hearth was used, of course, it had to be cleared of the stones, which could be reused until they became too fragmented by the heat. This interpretation is plausible and has been ethnographically documented, but there is another possible explanation. The idea may have been to heat the stones and then use them for boiling, roasting, or drying food; for drying and heating flint before knapping it; for heating antlers before working them; or for other purposes.

Indeed, the use of fire as a tool is easier to document than its use for warmth because the remains of materials worked in fire are modified in ways that we can still observe. For example, in some rare Lower and Middle Paleolithic sites, exceptional conditions have preserved wooden tools that were pointed and hardened in fire, such as the digging sticks at Kalambo Falls in East Africa and the spear of Lehringen in Germany. By the Upper Paleolithic, fire was used to fracture or treat flint, antlers, ivory, and bone and to reduce and oxidize natural ochers for painting. A first attempt at ceramics appears in fired figurines found in central Europe. And fire probably served as a tool in such activities as forest clearing, tree felling, and game hunting.

Fire's many technical applications, as well as its importance for cooking and lighting, make it hard to determine how important the Paleolithic fireplace was for heating. But what should be emphasized is that fire was neither the first nor the only way that humans discovered to fight cold.

A wind- and moisture-proof dwelling—a hut or tent—would have been one of the most efficient defenses against cold. The covers of tents or huts, which were probably made of organic materials, are not preserved, but the remains of stones, rings of pebbles, or folds of earth that were used to fix a cover to the ground can often be found. There were Paleolithic huts made of reindeer bones and antlers or mammoth bones and tusks that had an intricate dome structure to support and fix a heavy, weatherproof cover. Experiments have shown that a cover sewn together from reindeer skins (reindeer were widely hunted in Upper Paleolithic Europe) would have provided excellent protection against cold, rain, and snow.

The best protection would have been individual clothing, which conserves body heat. Unfortunately, nothing is known about clothing during the Lower Paleolithic, although fur clothes were probably used. Numerous bone and ivory needles from Upper Paleolithic sites indicate that clothes were being sewn some 17,000 years ago. Before that, sewing could have been done with bone or stone borers. To get an idea of the clothes themselves, we have to turn to figurines and burial sites. Most of the

female figurines from the Paleolithic era do not depict clothing, but there is at least one from Buret' in Siberia that is dressed: a slim figure depicted with trousers, a vest, and a hood, not very different from traditional Eskimo garments. In many Paleolithic burial sites, long rows of shells and beads on the head, body, and sometimes feet still show the shape of the cap, clothes, or shoes to which they were attached. And just at the end of Paleolithic times, one small boy was buried with a short-sleeved jacket made of red squirrel tails, whose bones have been preserved in perfect order (in the cave of Arene Candide, in Italy).

Many furry animals are carnivorous and, being dangerous quarry, are not usually appreciated for their meat. Thus, the remains of lynxes, wolves, foxes, and similar animals found at prehistoric sites suggest that they were sought for their fur, which was used for clothing, rather than their meat. Furs could also be spread on the ground and used as blankets. In the two-hearth hut in the cave at le Lazaret, the claws of furry animals were found to have the same spatial distribution as the shells of very small crustaceans that live on algae; it appears that the inhabitants spread beds made of algae and furs around the two small hearths. In most Upper Paleolithic habitations, the ground is heavily colored with ocher. Since ocher is still used by some peoples in the tanning of skins, it is possible that this coloring reflects, not the ritual spreading of ocher on the ground, but the much more prosaic use of furs and skins.

In sum, the traditional image of prehistoric humans in constant struggle against cold rests largely on an overestimation of the harshness of the climate and an underestimation of Paleolithic capabilities and technology. Moreover, the human body itself, helped by an appropriate diet, is able to develop natural defenses against extreme cold. In regions around glaciers, prehistoric hunter-gatherers ate marrow and animal fat in large quantities, and this may have been their most efficient means of resisting the cold. Despite the rather poor archeological data, we can conclude that human adaptation to cold in prehistoric times relied on a variety of factors and techniques. Someday, we may be able to distinguish specific cultural groups that adopted differing strategies of keeping warm. □

Buy 40 beautiful UNICEF note cards. And help a billion beautiful children.

This is the famous UNICEF Super Box Collection — 40 beautiful cards, including 15 note cards with envelopes, 15 minis with envelopes, and 10 multi-lingual inserts (Happy Birthday, Happy Anniversary, Thank You, etc.). Plus 10 petite gift enclosures.

It's a super value at only $9.

And the best part is, the proceeds help support health and education for a billion children in 111 nations. So *every* note you write is a love note to the underprivileged children of the world.

PS: The Super Box makes a super gift — a gift that says you're truly involved.

Famous UNICEF Cards. They say beautiful things about you. Before you ever write a word.

Eskimos Are Warm People

Their vision of hell is that of a cold place, and they have no intention of living it on Earth

Text and photographs by Fred Bruemmer

Since man originated in a warm climate, presumably Africa, this furless relative of the apes was poorly designed by nature to cope with cold. Naked humans today are comfortable at an ambient air temperature of about 75°F. At temperatures lower than this, we begin to feel chilly and respond by shivering, which roughly triples the body's heat production, and by having goose pimples, a pathetic vestigial attempt to fluff out the protective fur our forebears had. When the air temperature is low enough to sap body heat faster than it can be generated, the body's core temperature is lowered, and we are immediately in grave trouble. Our normal body temperature is 98.6°. At 91°, our thermoregulatory system begins to falter.

According to David E. Bass of the U.S. Army Research Institute of Environmental Medicine, "Man becomes incapable of conscious, lifesaving decisions when deep body temperature is lowered by only seven degrees. Furthermore, long before this point is reached, he has become subjectively so uncomfortable that he must spend 100 percent of his effort toward mere survival." A naked human exposed to −40° temperature and winds of thirty miles per hour—conditions common in the Arctic—would die in about fifteen minutes.

Given this hereditary sensitivity to cold, it is not surprising that the ancients living in southern climes contemplated the north with dread and loathing. In 430 B.C., the Greek historian Herodotus wrote about the northern regions of Europe: "The whole of the country . . . has so hard and severe a winter, that there prevails there for eight months an altogether unsupportable cold."

Yet people did live in the north of Europe. And at the same time, precursors of the modern Eskimos inhabited the much harsher North American Arctic, from Alaska to East Greenland and north to the very limit of land, on Ellesmere Island and in Peary Land. Today, in these regions, the mean January temperature is −30°, temperatures can drop to nearly −70°, winter storms are frequent, and the sun sets on October 20 and does not rise above the horizon again until early March. In the Thule region of northwest Greenland, home of the Polar Eskimos, only one month, July, has an average temperature above the freezing point. Yet contemporary Eskimos call this region *Nunassiaq*, "the beautiful land."

This may seem a strange description of the harshest, most hostile, and potentially most lethal environment ever inhabited by humans. But the prehistoric Eskimos, who knew only their land, did not think of it as being extraordinarily harsh or hostile. To them it was simply *nunavut*, their homeland, and until missionaries and explorers told them otherwise, they believed it to be the best of all possible worlds, a land and a sea rich in game. Nor did they necessarily find other lands and other climes more genial and alluring. In 1851, after a fruitless search for the missing Franklin expedition (whose 129 officers and crew all perished on their ill-fated search for the Northwest Passage), Capt. Erasmus Ommanney returned to England, taking with him Kallihiruas, a young Polar Eskimo from northwest Greenland. Kallihiruas lived for four years in Canterbury and, dressed in European clothes, was pitifully cold. In 1855, he wrote a plaintive letter to an English friend: "I been in England long time, none very well. Very bad weather. . . . I very sorry, very bad weather dreadful. Country very different. Another day cold. Another day wet. I miserable. . . ."

For a people whose ancestors have lived in the far north for at least 10,000 years, the Eskimos have few physiological adaptations to the severity of the climate. They can digest and assimilate fat better than Europeans. Their basal metabolic rate is 20 to 40 percent higher than that of people in more southerly regions. Their hands and feet are small, and in cold conditions, the blood flow to the extremities is more intense than in most other human groups. Vasodilation (the widening of blood vessels) permits abundant blood flow to the hands, and as a result, Eskimos have warm hands even in cold weather.

But while such physiological adaptations help protect hands and feet and, equally important for a hunting people, insure manual dexterity even in very cold weather, they are only minor components of the Eskimos' survival kit. To protect themselves from the lethal cold of the arctic climate, the Eskimos' forebears invented, in the words of the explorer Vilhjalmur Stefansson, "a system of living perfectly adapted to a cold climate. . . ." It took millenniums to attain this perfection.

Just when and where the Eskimos originated, and why they chose the Arctic as their home, are subjects of conjecture. People of Arctic Mongoloid stock probably came from Siberia across the Bering Strait to Alaska about 10,000 years ago, at a time when the ancestors of the Indians had already preempted most of North America except the Arctic. Some specialists think that these people are ancestral to both Eskimos and Aleuts and call them Eskaleuts.

For a hunting people, the Arctic had its attractions: millions of caribou, tens of thousands of musk oxen, millions of birds and seals, and plentiful whales and walruses. But for the first humans to colonize this game-rich but climatically

On the Belcher Islands in Hudson Bay, the Eskimos made parkas from the skins of eider ducks when caribou were not available. Eider parkas were light and warm, but more fragile than those of caribou fur.

Caribou skins are spread hair-down on the ground to dry, left. The Eskimo woman, right, is cleaning a caribou skin, preparatory to making it into a parka. Bannock is baking over the seal oil lamp.

daunting realm, life must have been an excruciatingly difficult struggle for mere survival. The people of the Arctic Small Tool Tradition, presumed to be descendants of the Eskaleuts, nevertheless spread eastward from Alaska about 5,000 years ago, and within a span of roughly a thousand years occupied the Arctic all the way north to Ellesmere Island and east to East Greenland. They lived year-round in small tents, which they probably could not heat because they apparently did not have oil lamps. They lacked the toggle harpoon so essential for successful sea mammal hunting. They probably had neither boats nor dog teams. Yet somehow they persisted, a few thousand people scattered across the immensity of the Arctic, leading a life so hard that later Eskimo cultures appear positively luxurious by comparison.

From these people of the Arctic Small Tool Tradition other cultures evolved—the pre-Dorset and, about 800 B.C., the Dorset culture, which spread from its core area in northern Hudson Bay and Foxe Basin, to northern Ellesmere Island, west to Victoria Island, and south to Newfoundland. The culture of the Dorset people was distinctly Eskimoan. They had more elaborate tools and hunting implements and a way of life much better suited to the Arctic than that of their predecessors. But the Eskimos' cold-adapted culture did not reach a state of near perfection until the arrival of the so-called Thule culture people, who moved eastward from Alaska about A.D. 800 and within less than 200 years spread across most of the North American Arctic, displacing or absorbing the Dorset people.

Superb sea mammal hunters, Thule culture Eskimos pursued and killed everything from the small ringed seal to the giant bowhead whale and, according to archeologist Robert McGhee of Canada's National Museum of Man, they had evolved "a technology more complex than that of any other preindustrial society, which allowed not only an economically efficient but also comfortable way of life throughout arctic North America." These Eskimos invented, perfected, and passed on to the Eskimos of historic times such a plethora of specialized tools and hunting equipment that the late James A. Ford of the American Museum of Natural History described them as "gadget burdened."

This is the more amazing because not only was their land exceedingly cold, hostile, and barren, it was also poor in those raw materials most societies have found essential. Metal was rare: meteoritic iron, brittle and hard to work, was found in the Cape York region of northwest Greenland and native copper in a few areas of the central Canadian Arctic. Driftwood was abundant along Alaska's coast and east past the Mackenzie River delta; it was rare in the eastern Arctic and virtually nonexistent in the central Arctic. That left stone, ice, snow, and sod as the most readily available and most widely used materials that the land and sea provided. Infinitely more important to the Eskimos were the materials they obtained from the animals they killed: bone, horn, baleen, antlers, teeth, ivory, furs, skins, sinews, and intestinal tissues. As Dionyse Settle, the Elizabethan chronicler of explorer Martin Frobisher's second expedition to Baffin Island, so shrewdly observed in 1577: "Those beastes, flesh, fishes, and fowles, which they kil, they are meate, drinke, apparel, houses, bedding, hose, shooes, thred, saile for their boates . . . and almost all their riches."

The earliest description of an Eskimo winter home comes from Frobisher's third voyage to Baffin Island in 1578. George Best, one of Frobisher's officers, wrote: "From the ground vpward they builde with whale bones, for lack of timber, which bending one ouer another, are handsomly compacted in the toppe togither, and are couered ouer with seales skinnes. . . ."

The Eskimos inhabited similar winter houses when anthropologist Franz Boas lived with them on Baffin Island in 1883 and 1884. The base of a house was built of stones and whalebones (occasionally incorporating entire whale skulls). The rafters and framework were made of whale ribs and jawbones. These were covered with seal or walrus skins, then came a thick layer of dried heath, and the whole was securely wrapped with a second layer of animal

In summer, Eskimos traditionally lived in caribou-skin tents. These provided ample shelter from rain and storms. The kayak, which was important for hunting, is made of depilated caribou skins.

skins. In winter the entire structure was covered with an ample layer of snow. A window was made by sewing together the translucent, parchmentlike intestines of a bearded seal, and stone slabs were used to pave the entrance: a long, low passageway that sloped upward to the hut. This entrance was the essential and ingenious feature of all Eskimo houses, whatever their design. Since warm air is lighter than cold air, none of it escaped downward through the entrance. Conversely, only enough cold air entered the building to replace the stale, hot air that seeped out of the vent in the top of the house, thus providing gentle ventilation without draft. "This kind of hut," said Boas, "is very warm, light, and comfortable." Such *qagmaqs*, made with wooden frames and canvas covers instead of skins, were still used in a few isolated camps on southern Baffin Island until the early 1970s.

In the western Arctic where driftwood was plentiful, house frames were built of timber and thickly covered with sod and snow. In 1827, Lt. Edward Belcher of the British expedition ship *Blossom* visited a native home at Point Hope, Alaska, and was "much surprised to find so much neatness, cleanliness and comfort in the great apartment." But he found the temperature in the house "very oppressive."

These one-room houses were nearly perfectly insulated and were warm even in the coldest weather. "The typical Eskimo house in the afternoon and evening (when lamps burned high to cook supper)," said Stefansson, "resembled a sweat bath," and the people in it sat stripped to the waist, sweltering. At night all lamps but one were doused to bring the temperature down to 50° or 60° and "both sexes and all ages slept completely naked, under light robes." About half the room was taken up by a raised sleeping platform built of stones and covered with dried heath or moss. On top of this layer, caribou furs were spread—usually the long-haired skins of early winter, the first layer hair-down, the second hair-up—to form a warm, soft, deep-pile mattress. In two or more *kudliks*—shallow, crescent-shaped lamps carved of soapstone with wicks made of a mixture of dried, rubbed moss and the bolls of cotton grass—seal oil or whale oil burned with one- to two-inch-high flames, providing both heat and light. Above these lamps the Eskimos cooked their meals, usually meat and fat and occasionally fish, in "pannes cutte and made of stone very artificially," as George Best in 1578 described the Eskimos' soapstone cooking pots shaped like miniature sarcophagi.

As long as hunting was good, oil for the Eskimos' lamps was never a problem. Since the Eskimos consumed about six parts of meat to one part of fat, seals and whales provided much more fat than the people and their sled dogs could possibly eat, and the surplus fueled the lamps. Fire was not a problem either. The Eskimos had both the fire drill, a device that produced fire by friction, and firestones, iron pyrites which were struck together to create sparks. With either method, they used as tinder the slightly oiled down of willow catkins upon a bed of dry moss. It rarely took more than three to five minutes to kindle a flame.

In those parts of the north where whales and, hence, whalebones were rare and driftwood was equally scarce, the Eskimos built their winter homes of

An Eskimo woman watches over her child in a summer tent. Living in tents and igloos has become uncommon throughout the Arctic as most Eskimos have moved into permanent, year-round housing.

snow. In their language, snow, depending upon its type and consistency, has more than a hundred names, and it once had many uses. Absorbent, though cold, it was used in lieu of toilet paper. Ingenious traps were built with snow and baited with urine to capture caribou. A windscreen of snow blocks protected the fisherman jigging for lake trout or char. And *oqaalugsait*, hard-packed, fine-grained snow deposited unlayered by a single storm, was perfect for building the igloo, that emblem of Eskimo culture and ingenuity, which according to Richard L. Handy of the Engineering Institute of the University of Iowa, has "a structural perfection . . . matched but hardly surpassed by modern engineering."

A long, thin probe of caribou antler with an ovoid ferrule at one end and a handle at the other was used to find suitable igloo snow. Then blocks, each roughly three to four feet long, two feet high, and six inches thick, were cut with a snow knife made of bone, ivory, or native copper. Men built the circular igloo, spiraling the snow blocks upward, with each successive tier canted slightly more inward to achieve a perfect dome so strong it could easily support the weight of an adult person. It took less than an hour to build a small igloo, used as a temporary shelter while traveling, and two to three hours to build the large winter home, fifteen feet in diameter and seven feet high, that would house an entire family. A pane of freshwater ice set into the igloo's south or east wall served as a window, and an upward-sloping entrance tunnel of snow blocks formed the essential cold trap that prevented the escape of warm air from the building.

The myriad air cells within the snow made it an excellent insulator. Just the body warmth of its inhabitants could raise the igloo's temperature by about forty degrees above that of the outside air. The igloo had, however, one major failing: heated with oil lamps to more than 42°, it began to melt and drip. Thus an ordinary igloo, although windproof and reasonably comfortable, was hardly cozy. But many all-winter igloos were lined with sealskins, leaving a cold-air space between the lining and the snow walls, and in such homes the temperature could be kept between 60° and 70°. In late spring, the sun-warmed igloos sagged and became uncomfortably dank, necessitating a move into tents made of seal or caribou skins.

As vital as their winter homes, which permitted them to live in reasonable comfort in an icy land, and just as ingenious, was the Eskimos' winter clothing, so perfect in design and material it made them nearly impervious to any arctic weather. Furless and extremely vulnerable to cold, Eskimos protected their bodies with the skins of the superbly cold adapted animals of the north. Musk oxen, cloaked in dense fur so long it hangs nearly to the ground, can endure, with little heat loss, storms of seventy miles per hour and temperatures of −50°. The long guard hairs and dense fur of arctic foxes protect them so well that they do not have to increase their metabolic rate until the temperature falls below −40°. The fur most important for the Eskimos, virtually the sine qua non of their survival in the Arctic, was that of the caribou. Caribou hairs are club shaped, thicker at the tips than at their base, so that they trap body warmth in tiny air spaces near the skin;

and each hair is filled with air cells. The fur is short but very warm; the skin is light but very strong.

The Eskimos made every effort to kill caribou for winter clothing (and for food) in August and early September when the fur is of optimum quality. Seven skins were required to dress a man, six for a woman, and four for a child. The skins were carefully cleaned of meat and fat, and laid hair-down upon pebbly ground to dry as quickly as possible. Once dry, the skins were scraped with several different types of bone or stone scrapers—a hard and tedious task shared by men and women—until they were as soft as chamois leather. An experienced Eskimo seamstress could take the measure of her man at a glance, cut the required patterns from the skins with her *ulu*, the half-moon-shaped woman's knife, then sew the pieces together with closely spaced, overcast stitches. Dried caribou (or narwhal or beluga whale) sinew was her thread, ideal because it is very strong and molds itself to leather but does not tear it. Her thimble was made of musk ox horn or of depilated bearded seal leather; her needle of the hard wing bone of a gull or goose.

A complete winter outfit consisted of an inner parka worn with the hair against the body, an outer parka worn fur-out, inner and outer pants worn in the same manner, fur stockings, boots, and mittens. Wolverine fur (or that of wolf or dog) was used for the ruff of the loose-fitting parka hood because hoarfrost formed by breath could easily be brushed from it. Stockings were made of caribou fur or the down-soft fur of arctic hare; the boot sole from extremely strong, stiff bearded seal leather; the upper portion of the boot of ringed seal leather. A layer of dried grass, usually replaced each day, was put into the boot to form an insole that provided extra insulation and absorbed moisture. Mittens were made of caribou skin, often with a palm inset of durable seal leather. The entire outfit weighed just above ten pounds. It was loose and airy enough to avoid sweating, yet warm enough to enable a hunter, as the Danish ethnologist Knud Rasmussen observed, to stand "motionless as a statue" above a seal's breathing hole "in a storm and in a temperature of about −50°C." One man, Rasmussen reported, stood thus for two days and two nights, tired but warm in his superlative clothing. "When an Eskimo is well dressed," said Stefansson, "his two layers of fur clothing imprison the body heat so effectively that the air in actual contact with the skin is always at the temperature of a tropical summer."

Aglow from the light of oil lamps, an igloo is a winter haven for its inhabitants. The air cells within the snow are excellent insulation, and the residents' body heat is all that is needed to raise the temperature inside the igloo 40 degrees above that of the outside air.

In a few places, caribou were not available and the Eskimos had to make their winter clothes of other materials. On the Belcher Islands in Hudson Bay, adverse weather killed all the caribou in the 1880s, and the people made their parkas of eider skins—light, warm, but fragile. The Polar Eskimos of northwest Greenland traditionally wore pants of polar bear fur, extremely warm and durable, but somewhat hard and heavy. In this region, too, caribou had died out and the Eskimos made their inner parkas of bird skins (dovekies or murres) and their outer parkas of the skins of arctic foxes.

Whatever the material, one thing was essential: the clothes had to be perfectly dry or they lost their insulating quality. At the entrance to each winter home stood an *anowtaq*, a snow beater of bone or wood, with which Eskimos brushed and beat all snow from their clothes before entering. The outer layers of clothing were left in a cold, dry anteroom igloo, or chamber, and socks, boots, and mittens were carefully dried each night on a webbed drying rack suspended above a seal oil lamp.

The Eskimos did not relish cold. Heaven, they told the explorer Charles Francis Hall on Baffin Island in 1862, was a place of eternal light and warmth. And their vision of hell, as explained to Hall, was even chillier and gloomier than the mist-shrouded Niflheim of the Norse: "Always dark. . . . No sun . . . snow flying all the time, terrible storms; cold, very cold; and a great deal of ice there." Although they did not like the coldness of their land, they did not fear it either. Cold was a nuisance rather than a threat. Their superb cold-adapted culture shielded them from its lethal sting. □

Enduring Cold the Japanese Way

In Japan, people warm themselves, not their drafty houses

by Amanda Mayer Stinchecum

"A house should be built with the summer in mind. In winter it is possible to live anywhere, but a badly made house is unbearable when it gets hot." These words, written by the Buddhist priest Yoshida Kenkō in the fourteenth century, still reflect the feelings of the Japanese people. Lady Lawson, a traveler to Japan in the early twentieth century who, being English, was used to cold, damp winters, wrote of the Japanese house in winter:

> I believe the Japanese love to sit in draughts. On a cold, frosty morning, a paper house does not seem the right thing in the right place, and paper windows are inadequate, as the shivering foreigner feels. On these occasions, I used to recall Pierre Loti's dictum, that Japan was a tropical country which had moved up north by mistake and had never found it out.

It would be risky to state that the Japanese do not feel the cold as keenly as Westerners do, but there is no question that they are more stoic. Edward Sylvester Morse, who went to Japan in the late 1870s as a marine zoologist and became fascinated with Japanese culture, described his experience in Tokyo:

> Occasional snowstorms have occurred this winter but the jinrikisha men do not seem to mind the snow and run in it barefooted, and when standing the steam is seen rising from their bare feet. Curiously enough, the houses appear as open as in the summer. The children are barelegged, just as in the summer, and play in the snow without minding the cold.

In general, instead of seeking to change an uncomfortable or difficult situation, the Japanese accommodate themselves to it or, more often, endure it so as not to make anyone else uncomfortable. They frequently speak of the necessity of putting up with things or being resigned to them. This attitude of accommodation is perhaps at the root of the Japanese approach to dealing with cold: they warm themselves, their individual bodies, rather than their environment. And this, in turn, is tied to the way they think of the space they inhabit.

The traditional Japanese house and garden form an integral unit, separated by a wall from the surrounding community and from raw nature. The garden usually lies on the south side of the house, although its shape varies as part of the overall design. Particularly in smaller towns and in the country, the garden may adjoin rice fields, vegetable gardens, or even uncultivated land, and the wall surrounding it and the house may be simply a living hedge of bamboo or other foliage. Nevertheless, the garden is not part of nature but a reconstruction of it that belongs to the space of the house. It is not a backyard to sit out in on hot summer nights, but a setting for seasonal changes to be viewed in safety from one's living room. In order to appreciate the poignancy of the passing seasons, the Japanese observe the garden, even in winter, not through narrow panes of glass, but with the sliding doors thrown open as wide as possible. In her *Pillow Book*, Sei Shōnagon, the great diarist and wit of Japan's early eleventh-century court, described with delicacy a typical scene at the palace in Kyoto:

> In winter the early mornings [are loveliest]. It is beautiful indeed when snow has fallen during the night, but splendid too when the ground is white with frost; or even when there is no snow or frost, but it is simply very cold and the attendants hurry from room to room stirring up the fires and bringing charcoal, how well this fits the season's mood! But as noon approaches and the cold wears off, no one bothers to keep the braziers alight, and soon nothing remains but piles of white ashes.

As one might guess, the inhabitants of Kyoto do not face winters of extreme cold. The four main islands of the Japanese archipelago extend south to north as far as the United States does from Mobile, Alabama, to Bangor, Maine, but more than two-thirds of Japan's population lives in temperate regions south of the thirty-sixth parallel. Japan's major metropolitan centers are concentrated between 35° and 36° north latitude, the same as the central third of the state of North Carolina. In this zone, temperatures in January average 32° to 39°F, and people who live in such cities as Tokyo, Nagoya, Kyoto, and Osaka may see snow only once or twice a year. Even in the northernmost and more mountainous regions of the main island of Honshu, the January temperatures, warmed by the Japan Current (*Kuroshio*), average from 18° to 32°.

Hokkaido, the most northern of Japan's main islands—and the coldest—is a case apart. Originally inhabited by the Ainu, a racially and culturally distinct people, Hokkaido did not have large numbers of Japanese settlers until the nineteenth century. In general, the architecture follows the European more than the Japanese tradition, and the life style also reflects the strong Western influence that followed the Meiji Restoration in 1868. Faced with snowy winters, the settlers of Hokkaido, by necessity, departed from the original Japanese patterns. A description of traditional attitudes does not apply to Japan's truly cold region, therefore, but to the more characteristic temperate areas, where nevertheless, the dampness of the climate, combined with features of Japanese architecture that preclude efficient heating, contributes to an experience of winter that can be uncomfortably cold for weeks or months on end.

The traditional Japanese house is un-

Bruno Zehnder

suited for heating not only because of its integration with the garden but also because of its construction. Like the modern skyscraper, it is supported by its frame. The exterior walls serve mainly to enclose the space, block the wind, and give a sense of privacy. Sliding doors of paper or glass often constitute one entire side of the house, sometimes more, depending on how extensive the garden is. These provide no insulation from the cold, and the *amado* (storm doors) that are drawn across at night or during heavy storms are only made of a single layer of wood or thin aluminum. Inside, the rooms are small and the ceilings are low, helping somewhat to retain heat. But the walls of the rooms consist of *fusuma* (opaque sliding screens), which are flimsy and light and can be lifted out of their grooves to open up the interior space. Between the top of the *fusuma* and the ceiling there is often a wood or bamboo latticework transom, which is intended to aid ventilation and cannot be closed to conserve heat.

The traditional house is designed for winter in only one way: it is built with maximum southern exposure. Usually the best room in the house faces south, where the garden is located. In a well-designed house, the overhang of the roof is sufficiently long on this side to block the rays of the summer sun. On sunny days in midwinter, the doors are thrown open to let in the sunshine and air the house, and the bedding is hung from an upper balcony railing to air it and warm it up for the cold night ahead.

The Japanese have traditionally used charcoal fires for heat, but these mainly warm individual bodies rather than the space surrounding them. There are three types of arrangements for burning charcoal. The most basic is the *ro* (fire-pit or hearth), a square or rectangular pit framed with heavy timbers and lined with stone or brick, which is built into the tatami-covered floor. The *ro* is not usually seen in city houses, except in the tea room if there is one; it is more prevalent in rural areas, where wood may be burned instead of charcoal. The *ro* is used for heating water for tea, for warming the hands, and for cooking certain one-pot meals, but not for cooking regular meals; for this task, there is a separate cooking stove, often in another area of the house. The fire in the *ro* is kept low, and because the ceiling above it is often left open to the rafters to allow the smoke to escape, its capacity to heat interior space is limited.

The *kotatsu* is the most effective heating device and is still widely used, although not in its charcoal-burning form. It originated as a wooden frame set over the *ro* and covered with a quilt to keep the heat from escaping. Feet and legs were pushed under the quilt, warming the lower half of the body. A more elaborate arrangement is the *hori-kotatsu*, or sunken *kotatsu*, a deep pit in the floor, usually in the main sitting room of the house. A wooden grating is set over the burning coals of the *hori-kotatsu* and over the whole pit is placed a low table covered with a quilt. People sit around the table Western-style, that is, with their legs hanging down into the pit, and cover themselves from the waist down with the quilt. For meals and other activities requiring a hard surface, a separate tabletop is set over the quilt. Some traditional houses, even recently built ones, still have *hori-kotatsu*, but these are usually electrically heated. The common modern adaptation of the *kotatsu* is a low table frame with an electric heating element attached to the underside; the quilt is placed over this, and then a tabletop (usually of Formica, although in an elegant house it may be made of beautifully finished wood).

The third of the charcoal-burning devices is the hibachi, a brazier or firebox, which bears little resemblance to the grill Americans use to cook meat outdoors. Made of pottery or of wood lined with copper, this device is used for burning a few small pieces of charcoal on a bed of finely sifted ashes. The hibachi is designed primarily to warm the hands or to heat water for tea. Old woodblock prints frequently depict its use in a room open to a snowy garden. Before the introduction of electric, gas, and kerosene heating stoves, the hibachi was often the only source of heat in a city dwelling. Morse remarked on his own quarters in Tokyo:

> My only stove is a square wooden box in which is a round earthen vessel filled with ashes. . . . Ice has already formed outside and my room would be very cold without the little charcoal fire. I have become accustomed to the carbonic gas, though most of it settles through the cracks of the floor; when it gets too strong, I open the door. On enquiry I found that the Japanese never suffer any inconvenience from burning charcoal, their sole means of heating. The old woman who . . . brings in a few hot coals from her own hibachi had never heard of the gas being injurious, nor had she an idea that it could kill one.

The cost of charcoal has risen so high, however, that the charcoal-burning hibachi has all but disappeared: it is now a luxury reserved for such gracious pursuits as the tea ceremony. Gradually, kerosene, gas, and electricity have replaced the traditional fuel. Believed to present less danger of conflagration,

electricity and gas were preferred until the recent "oil shock," when the cost rose so dramatically that many Japanese switched to kerosene. Some of the new fixtures—usually small, portable stoves—are space heaters. Because of the unpleasant fumes from both gas and kerosene, however, such stoves are used only intermittently, and not at night, when the house is more tightly closed off by the storm shutters. In general, fires are not left burning unattended, or at least not with sufficient heat to keep a room warm. On a frosty night, bedding remains the primary retreat from the cold.

Japanese bedding, called *futon*, consists of a set of mats and quilts filled with cotton batting or silk floss. An underpad is spread first, then one or more top quilts, depending on the degree of cold. In the West, people often cling together in bed for warmth in the winter, but in Japan most adults sleep in individual beds. The *futon* are likely to be placed immediately adjacent to one another, however, because in Japan sleeping is a social activity. The members of a household and their guests usually sleep together in a few rooms, rather than spreading out one to a room, even where the size of the house permits it. And up to the age of six or seven, children often sleep in their mother's beds. These sleeping customs, however, seem to derive from a need for security rather than warmth.

In addition to the bedding itself, there are a number of devices to warm up a cold bed. One is the hot-water bottle, dear to English hearts, but in Japan it is made of metal or ceramic instead of rubber. Morse also describes "a little wooden box . . . used for the purpose of holding an earthen receptacle for coals, and this is taken to bed as a substitute for the hot stone or brick which is often used at home for a similar purpose." Both of these have now generally been discarded in favor of the electric blanket; the type that is spread under the sleeper seems to be preferred to the kind that is used as a cover. Sometimes the bedding is placed over or around an electric *kotatsu*, the low table with an electric heating element attached to the underside. Sleepers lie with their feet under the table, and the whole bed is warmed. This is considered a dangerous arrangement, however.

As bedding is used at night, so clothing is used by day to conserve body heat and keep the individual warm. One item, the *dotera*, or *tanzen*, is actually a cross between a kimono and a *futon*, that is, between a garment and bedding. A heavily padded, oversized kimono with wide sleeves, it can be drawn around the body or spread over the bedding for extra warmth.

The traditional layers of clothing include, for a woman, a *koshimaki* (wrapped underskirt) or *nagajuban* (underkimono), two or more of which are worn in cold weather. Over these a woman wears a kimono and either a *haori* (jacket) or *hanten* (padded jacket). The *hanten*, which is less formal than the *haori*, is available in a version large enough to cover an infant carried on its mother's back. A man would wear long underwear, and his kimono would be padded or would be covered by a sleeveless vest.

This use of layers of clothing is a practical solution to the problem of cold in a culture in which people do not traditionally wear either furs or fleece. Because Buddhism prohibits the killing of animals, the use of furs never became widespread in Japan, although now they are sought as a Western-style luxury item. And because sheep were not a part of the rural household, wool was not available for winter clothing until relatively recently. Before industrialization, Japan was an agrarian society in which domestic animals did not play a major role. Rice was cultivated by human labor, and meat was rarely eaten until the custom was introduced from the West in the sixteenth century.

Traditionally, farmers and poorer urban classes wore hemp cloth year-round, while the wealthier classes wore clothing padded with silk floss. The cultivation

While watching television, a family keeps warm under the quilt of their kotatsu, *a low table with an electric heating element underneath. Enclosed by opaque* fusuma *and white paper shoji screens, the room itself is unheated.*

John Launois, Black Star

and production of cotton, introduced into Japan by the late sixteenth century, became widespread during the eighteenth. Cotton was found to be much warmer than hemp and soon became the preferred material, thickened in various ways to make it warmer. Both adults and children wore kimonos and jackets padded with cotton batting. To give garments added strength and warmth, a quilting stitch, called *sashiko*, could be used either on a single layer of cloth or to join two or more layers of cotton. In northern Japan, where the climate precluded the cultivation of cotton, the people made cotton cloth from used kimonos or rags. They tore these into strips and wove the strips together into a heavier and more durable cloth. In Japan today, those who wear Japanese-style clothes have the advantage of wool kimonos; they may also wear shawls over their kimonos and, underneath, long underwear and sweaters.

The Japanese once made use of paper clothing, or *kamiko*, which was originally worn by Buddhist priests (since paper garments could be seamed with paste, no woman had to touch them). By the end of the seventeenth century, *kamiko* were also worn by ordinary people, especially to ward off the cold on journeys. The paper was coated with persimmon tannin to make it strong and waterproof. The seventeenth-century haiku poet Matsuo Bashō mentions carrying a *kamiko* when he started off on his journey to the far north: "Setting out with nothing but what I could bear myself, I carried a stout paper raincoat to keep out the chill at night."

Various kinds of rushes and rice straw were once used for raincoats, footwear, and hats. Besides being water-repellent, the hollow straws provided some insulation against the cold. In rural areas, sedge hats are still worn as protection against sun, rain, and snow. In earlier periods the Japanese wore many kinds of hats as signs of rank and for protection in battle or against the elements, and hoods were worn for warmth by women, old men, and priests (who shaved their heads). But today the Japanese rarely wear hats except to shade themselves from the sun or to keep off precipitation. While Westerners concentrate on keeping their extremities warm, donning hats, scarfs, gloves, and warm socks when the weather turns chilly, the Japanese seem unconcerned about such items of clothing.

Japanese tradition places the seat of a person's being—the spirit, the emotions, the breath—in the belly (*hara*): if the belly is kept warm, the person will be warm and healthy. The *haramaki*, or belly band, often a knitted wool tube about six inches wide, keeps the abdomen warm. Once more common, *haramaki* are worn today primarily by workmen who are exposed to the cold, by pregnant women, and by children. In fact, *haramaki* are built into children's pajamas. Another device for heating the belly or chest, used since the beginning of the eighteenth century, is the *kairo*, a small container filled with smoldering ashes, which is worn tucked under the sash or into the folds of the kimono. In earlier periods, a heated pumice stone wrapped in rags was similarly used.

The Japanese warm their insides as well. In winter they drink hot tea, of which there are many types, almost continuously. The tea not only warms the middle, but the handleless teacup warms the hands as well. And while all cultures with cold winters have their own special hot drinks for cold nights,

Paul Chesley, Aspen

In winter, women at a hot spring resort in Beppu, on the island of Kyushu, are comfortable in light clothing and bare feet. The unlined striped cotton kimono, hanten *jacket, and wooden clogs are issued by their inn.*

Family members as well as strangers share the bath at a country inn, soaking in the hot water after washing themselves outside the tub. Often a social occasion, the bath is a favored way to relax and get warm.

John Launois, Black Star

the Japanese heat their rice wine, sake, in all but the hot, summer season. In Japan, drinking liquor is a social activity—pouring one's own drink is considered inappropriate.

Meals also take on a more communal quality in the winter, creating more warmth in a room. A special category of dishes, called *nabemono*, or one-pot meals are prepared at the dining table. Into a pot of boiling broth, the hostess plunges various combinations of vegetables, fish, chicken, and meat. When these are just barely cooked, each diner fishes out a portion and dips it into an individual bowl of sauce. Sukiyaki, an American favorite, is a *nabemono* dish. This type of cooking originated in the rural and the more northern areas of Japan where the open hearth was a common feature of domestic architecture. On a cold night, the heating element—originally the *ro* but now a gas burner or electric ring—and the simmering broth warm the people huddled around the table. Other hot foods prepared in winter include noodles served in steaming broth, and sweetened bean paste, thinned to the consistency of a thick soup and served with pieces of rice cake in it.

The one place where the Japanese can feel totally surrounded by warmth, however, is the bath. It is the best way to relax before going to sleep, and a long soak in the near-scalding water warms the body for hours afterward. For the Japanese, who are more oriented toward the group than are Westerners, the bath is, more often than not, a social activity as well. The public bath provides an occasion for social relaxation and gossip. In cities and small towns, there is always one, often two, within walking distance of most households. Many Japanese who live in apartments or boardinghouses, such as students and unmarried men, do not have their own baths, while in some older houses the large tub must still be heated by building a wood fire under it. Even when a gas flame is used, preparing the bath at home is time-consuming (as well as costly). At the public bath, on the other hand, for a modest fee there are unlimited quantities of hot water and, in Tokyo and Kyoto at least, sometimes whirlpool baths and saunas. Cold beer, milk, and soft drinks are available in the changing rooms, the television is tuned to the most popular melodramas or the evening's baseball game, there is the opportunity to visit with one's neighbors and friends, and someone else cleans up.

An extension of the amenities offered by the public bath can be found at the numerous hot spring resorts scattered throughout Japan. Hot springs are more popular during the warmer seasons, but to spend New Year's at a hot spring is one of the delights of winter travel in Japan. Guests spend hours in the pools, indoors and out, sipping cups of tea or sake while they soak.

The Japanese have turned in recent years to methods of heating the environment rather than warming individual bodies: they are beginning to install central heating in newly built apartment houses and even in single-family homes. Mainly because of the rising cost of fuel, however, this is still the exception rather than the rule. Ingrained attitudes toward enduring the cold and enjoying the natural beauties of the winter season, longstanding architectural customs, and the energy crisis all contribute to the retention in Japan of a traditional approach to keeping warm. □

ACTUAL SIZE OF PLATES IS A FULL 9¼"

The Refanu

The Flying Dutchman

The Pride

Affordable beauty to treasure forever...

Legendary Ships of the Seas

The ten great sailing vessels of history and legend... captured forever on limited-edition porcelain art plates.

Examine the first legendary ship, "The Flying Dutchman," for 15 days without risk.

Strict Edition Limit: 19,500 worldwide
Your Reservation should be mailed by November 30, 1981.

A love of the sea lies deep in the hearts of us all. We often imagine ourselves sailing away on a romantic clipper into a golden sunset... enjoying a life of leisure on a fabled pleasure ship...living out the adventurous tales of the sea.

Now, from the renowned house of Royal Cornwall®, Ltd. and the brush of acclaimed artist Alan D'Estrehan come the *Legendary Ships of the Seas:* 10 magnificent sailing ships captured for eternity on exquisite porcelain.

Relive these ageless stories of the most celebrated sailing ships of fact and fantasy. From the giant paradise vessel "The Refanu," whose towering masts must be lowered for the ship to pass under the sun and moon ... to "The Pride," the romantic brigantine of pirate Jean Laffite, still seen gliding through the waters of Galveston Bay... here are the most vivid portraits of sailing ships ever created on porcelain, a collection of beauty and romance to grace your home and enrich your life forever.

The premier plate series by renowned artist Alan D'Estrehan

The magnificent paintings for this series are the creations of award-winning artist Alan D'Estrehan. A descendant of John Singer Sargent, one of America's most renowned painters, D'Estrehan carries on the same tradition of impeccable artistry that is the hallmark of his famed relative. Widely exhibited and critically praised throughout Europe and America, D'Estrehan debuts in the collector's plate field in brilliant fashion with *Legendary Ships of the Seas*.

With his intense passion for the sea and his rare artistic ability, Alan D'Estrehan was the perfect choice to create the paintings for this series. In order to capture the very essence of these legendary ships, D'Estrehan spent two years studying the log books of ancient ships and poring through the actual eyewitness accounts. The result of his labor and talent is a limited-edition art collection that vividly and accurately captures the lure of the sea and the authentic details of the famous ships of legend.

Affordable beauty for your home

Imagine all 10 *Legendary Ships of the Seas* proudly arranged on your bookshelves, or gracing your walls in an eye-catching array of colors. From the vibrant scarlets of the banners in Queen Anne's flagship "The Gaspé Bay"...to the icy silver and blue of the phantom vessel "The Rescue," every shade and hue glows from the gleaming surface of the fine Royal Cornwall porcelain.

Despite all the care and craftsmanship lavished on each of the plates, *Legendary Ships of the Seas* represents an easily affordable collecting opportunity. The cost for each fine plate in the collection, measuring a full 9¼ inches in diameter and banded in a ring of shimmering 24 karat gold, is only $49.50, to be billed in two equal installments for your convenience. The plates will be sent one every other month.

To be guaranteed acceptance, please reply no later than November 30, 1981

Examine the first plate, "The Flying Dutchman," for 15 days. Relive the haunting tale of the ship's captain, a man fated to sail the seas forever, unless he can find a pure maiden who will love him with all her heart. If "The Flying Dutchman" fails to please, simply return it for a full refund or charge-card credit and you will be under no further obligation.

Included with each plate is a Certificate of Authenticity bearing the plate's registered number within the limited edition. Your number remains the same through all 10 plates, giving your set the highly desirable distinction of a perfectly matched collection.

Legendary Ships of the Seas marks a major collecting opportunity worth your serious consideration, for several reasons:

- The enduring theme of nautical art has traditionally been among the most popular subject matters in the history of limited-edition plates.
- *Legendary Ships of the Seas* brings the illustrious naval artist Alan D'Estrehan into the plate collector's field for the first time. "Firsts" historically spell profitability for collectors.
- The enduring value of this collection is assured by its strict edition limit. Once the limit of 19,500 has been reached, the collection will be closed forever.
- Finally, and perhaps most important, the great art itself is gallery quality. Ten beautiful ships come alive in the masterful artistry of Alan D'Estrehan.

Your *Legendary Ships of the Seas* will make an heirloom collection you can be proud to own and display, and even prouder to pass down to future generations.

The backstamp attests to each plate's authenticity at the time of any future resale.

Shivering Finches

For some small birds that don't fly south for the winter, extra fat and shivering may boost their chances for survival

by Cynthia Carey and Richard L. Marsh

Chilled to the bone by the cold wind as we skiied through the woods one snowy day in Michigan, we were looking forward to a cup of hot chocolate and a warm fireplace. Rounding a bend in the trail, we were surprised to see a flock of small birds noisily foraging in bushes blown free of snow. We knew that most avian species that breed in arctic and temperate climates migrate to warmer areas for the winter and that only a few hardy species remain all year as permanent residents. Migratory birds possess orientational, behavioral, and physiological traits that enable them to migrate successfully, and we wondered what kinds of adaptations enabled resident birds to survive cold winters.

In many respects, the problems associated with staying warm in cold climates are similar for birds and mammals, such as humans. Both birds and humans maintain high body temperatures (104° and 98.6°F, respectively) by internal production of heat. Such heat production is sufficiently great that body temperatures are raised above external air temperatures, somewhat as a furnace heats a house above the outside temperature in winter. The temperature inside the house is maintained at a comfortable and constant level by a thermostat, which turns the furnace on and off. Colder air temperatures increase the rate of heat loss from the house and require the furnace to produce heat for longer periods of time than milder temperatures do.

Animals, however, produce heat, and regulate heat production, by methods different from that of a furnace. All living things produce heat by releasing energy stored in the chemical bonds in their food, specifically in carbohydrates, lipids, and proteins. Some of this energy is temporarily stored in the high-energy bonds of adenosine triphosphate (ATP) molecules, which can then be used as the energy source for all the cellular and physiological functions necessary for life, such as ion transport across membranes, synthesis of cellular components, and contraction of heart and skeletal muscle. The transfer of energy from the chemical bonds in the foodstuffs to ATP is not very efficient: about 60 percent of the energy is lost immediately as heat. Furthermore, as ATP is used for various metabolic functions, all the energy in the original foodstuff ultimately becomes heat energy. Since the production of ATP requires oxygen and produces carbon dioxide, physiologists usually estimate heat production by measuring the amount of oxygen consumed or carbon dioxide released by an organism.

Animals, unlike furnaces, do not periodically turn off their heat-producing mechanisms. Maintenance of living tissue requires continual production of ATP, which constantly generates heat. The minimal level of metabolic processes needed to maintain life, called the basal metabolic rate, produces enough heat to maintain a 98.6° body temperature in a nude human at air temperatures down to about 73.4°. If air temperatures fall below that level, the maintenance of constant body temperature requires additional heat, which both humans and birds produce by shivering. During shivering, antagonistic muscles contract simultaneously, so no external work is done. Thus, all of the energy used in contraction appears as heat inside the body. The principal compounds supplying the energy in the muscles are glycogen (the storage form of glucose) and triglycerides (lipids composed of fatty acids and glycerol). In severe cold, shivering can elevate the metabolic rate as much as five times above the basal level.

Cold-climate birds, the majority of which are diurnal, have a large requirement for food to fuel the costs of shivering. The short periods of daylight in northern latitudes, however, reduce the amount of time for foraging, and inclement weather, snow cover, or ice may further restrict food availability. The problems of staying warm must be particularly intense for small birds weighing less than thirty grams. Because small birds have a large surface area relative to their volume, their problems of heat loss are relatively more severe than those of larger birds. Smaller birds are also relatively less insulated than larger ones since their size limits the thickness of the insulative layer. Finally, calculations by William A. Calder of the University of Arizona suggest that larger birds can endure fasting under cold stress for longer periods of time than smaller ones.

The problems encountered by small birds in cold climates have stimulated considerable research during the past thirty years, most notably by the late J. Stanford Hart of the National Research Council of Canada, George C. West of the University of Alaska, and William R. Dawson of the University of Michigan. Their efforts and the work of others have established that wild birds use a combination of two general means to cope with cold: mechanisms that reduce the amount of heat required to maintain a high body temperature and mechanisms that allow high levels of heat production for long periods of time.

One of the ways birds can reduce the amount of heat they must generate in the cold is by increasing their insulation, an advantage that should be obvious to anyone who has put on a down jacket on a cold winter day. Extra feathers reduce the rate of heat loss and the requirement for additional heat production. Since the thickness of plumage is limited in small birds, larger birds can utilize seasonal variation in plumage insulation more extensively. The plumage of a 550- to 650-gram willow ptarmigan (*Lagopus lagopus*) in Alaska, for example, varies seasonally not only in color—from brown in summer to white in winter—but also in insulative value. Because of the difference in insulation, the heat

To maintain normal body temperatures in the winter, goldfinches and other small birds produce heat by shivering. Some birds also adapt to cold by growing additional feathers or seeking protected roosts.

Larry West; Bruca Colaman

production required for the ptarmigan to maintain a high body temperature is the same at 32° in summer as it is at −13° in winter.

Many small birds wintering in cold climates also appear to reduce their heat-production requirement by seeking protected roosts in dense vegetation, crevices in snow, or cavities in rocks or trees. These roosts protect against direct exposure to precipitation and the chilling effects of wind, and they reduce radiant heat losses to the night sky. S. Charles Kendeigh of the University of Illinois noted that the body heat lost by house sparrows (*Passer domesticus*) in wooden roost boxes warmed the air inside the box and contributed to a substantial energy saving during the night. Observations by Brina Kessel of the University of Alaska of the activity of chickadees (*Parus atricapillus*) in Alaska suggested that these birds remained in their roosts for longer periods during the daylight hours and foraged for shorter periods during cold spells (at temperatures of about −58°) than on milder days. This behavior would reduce the high heat losses incurred by the movement of plumage during flight, thereby conserving energy reserves.

In addition, some small birds, most notably chickadees, may not expend the necessary energy to maintain high body temperatures at night. Susan Chaplin of Cornell University found that body temperatures of chickadees exposed to 32° in the laboratory dropped eighteen to twenty-two degrees during the night. This nocturnal reduction in body temperature—known as hypothermia—is a normal phenomenon from which the birds recover spontaneously the next morning. If it occurs under natural conditions in the field, hypothermia can save the birds up to 23 percent of the estimated energy required to maintain normal temperatures.

Although small birds may use increased insulation, protected roosts, and/or nocturnal hypothermia to reduce the requirements for heat production and husband their energy resources in winter, they must also be able to sustain high levels of heat production for long periods. We believe that they probably shiver continuously all winter except during periods of flight, when muscle contractions associated with flying also produce heat substantially above basal levels. The general question of how small birds produce high levels of heat for long periods has not received much attention, and it was this area that excited our curiosity on our cross-country ski trip.

Our interests coincided with the research of William R. Dawson, who was then our professor at the University of Michigan and who has spent nearly twenty years investigating avian metabolic adaptations to cold climates. Joining forces with him in an attempt to discover more about the heat-generating capacities of birds, we selected the subfamily Carduelinae, which includes goldfinches, house finches, pine siskins, crossbills, redpolls, and pine grosbeaks, for our studies. The cardueline finches are ideal for our purposes since the majority weigh less than 30 grams, the geographical distributions of many species are primarily northern, or boreal, and populations of many species are year-round residents in cold climates.

American goldfinches (*Carduelis tristis*), the first subjects of our study, weigh 12 to 15 grams and are widely distributed throughout North America. The winter distribution of the eastern subspecies extends northward into southern Canada, but some individuals may migrate into the southern states in winter. Banding records accumulated by the U.S. Fish and Wildlife Service indicate that members of the local population in southern Michigan, where we worked extensively, may remain in the area all year. Interestingly, however, individuals may migrate in some years and not in others: a bird banded in Alabama one winter was recovered in Michigan the following January.

Our first goal was to characterize the thermogenic, or heat-generating, capacities of goldfinches. In our experiment, both temperature and time were factors, since the ability to produce large amounts of heat and to sustain this high level of thermogenesis is important for survival in the cold. We devised a chamber in which the temperature of the air surrounding the bird was lowered from approximately 32° to −94° over a period of an hour and a half. Although these birds probably never encounter such severe cold stress in nature, this technique elicited the desired large thermogenic response. We felt that the technique would also prove useful in comparisons of the thermogenic capacities of species or of individuals within the same species captured in various seasons; J.S. Hart had previously established that differences in the ability to withstand severe cold are demonstrably

correlated with differences in survival time at more moderate temperatures.

As the air temperatures in the chamber cooled, the goldfinches elevated their metabolic heat production, measured as oxygen consumption, to offset the progressively higher rate of heat loss. By the time the air temperatures fell to −94°, the birds were producing heat at about 5.5 times the basal level to maintain a gradient of approximately 198 degrees between body and air temperature. Individual birds were retained in the chamber as long as oxygen consumption rose or remained stable, which indicated heat production was adequate for maintenance of body temperature, and were removed from the chamber when oxygen consumption fell, indicating the birds were no longer able to sustain heat production.

When goldfinches captured in summer in southern Michigan were subjected to this test, they were able to withstand only a few minutes at temperatures below −76° before oxygen consumption dropped and they became severely hypothermic. In contrast, we were impressed to learn that the goldfinches trapped in winter could sustain necessary levels of heat production for six to eight hours below −76°. Sampling birds from our area of Michigan every month of the year we found that the seasonal variation in thermogenic ca-

Under experimental conditions, goldfinches captured in winter can endure more cold than those caught in summer. The difference is largely due to seasonal variation in the capacity to store and use metabolic fuels involved in heat production.

Michael J. Kopiak for the Cornell Laboratory of Ornithology

pacity correlated nicely with the prevalent weather conditions. Heat-generating capacities, measured in terms of both the maximum level of heat production and the ability to sustain thermogenesis, increased as ambient temperatures dropped in the late fall, reached their peak in January, and then declined in the early spring. Birds sampled in the warmer months of April through October exhibited only marginal abilities to cope with cold.

To investigate the mechanisms underlying the striking seasonal variation in thermogenic capacities in goldfinches, we looked for three types of physiological adjustments that might enhance these capacities in winter: an increase in the ability of the heat-generating tissues to utilize oxygen and to oxidize metabolic fuels for the production of ATP; an increase in the supply of triglyceride and glycogen to thermogenic tissues; and a seasonal shift in the relative importance of triglyceride and glycogen as fuels for shivering.

The pectoralis muscles of birds serve both as the major flight muscles and as the primary site of shivering thermogenesis. We first investigated whether the mass of these muscles varied seasonally since an increase could indicate a change in the total amount of thermogenic tissue. We found that the pectoralis masses, which make up 20 percent of the body mass, do not vary with the seasons. We then tested the oxidative ability of this muscle, that is, its ability to use oxygen to catabolize fuel. (Catabolism is a metabolic process involving the breakdown of the complex materials of living tissue and the release of energy.) An analysis of the activities of two enzymes in the tricarboxylic acid cycle—a metabolic pathway that requires oxygen and metabolic derivatives of either glycogen or triglyceride to produce ATP—did not show a seasonal change. The oxidative capacity of the goldfinch pectoralis muscles was, however, among the highest found in vertebrate muscle. We believe that the lack of seasonal variation in oxidative capacity or muscle mass in goldfinches can be explained by the basic characteristics of avian flight muscle. In some species, flight may require an elevation of metabolic rate to more than ten times the basal level. Therefore, the evolution of flight may have necessitated the development of pectoralis muscles with oxidative capacities that are not only adequate to sustain long flights but also ample for prolonged thermogenesis.

Our second area of exploration was the possibility that the seasonal change in thermogenic capacity was related to a yearly variation in availability and mobilization of fuels for shivering thermogenesis. We found that body masses of goldfinches fluctuated from 12 or 13 grams in summer to 15 or 16 grams in winter. The body component responsible for most of this variation was triglyceride, which ranged from less than 0.5 grams in summer to nearly 2 grams in winter. Laboratory tests confirmed that triglyceride was mobilized from storage depots and oxidized by the birds during cold stress, and the resultant decline in the triglyceride content of birds tested under conditions of severe cold (−94°) and moderate cold (14°) accounted for most of the heat production. The seasonal variation in the triglyceride content of goldfinches thus closely paralleled the yearly change in thermogenic capacity, evidence that the ability to store triglyceride and to mobilize it rapidly plays an important role in the success of goldfinches in cold climates.

Our studies of substrate utilization by shivering goldfinches clearly indicated, however, that the seasonal shift in triglyceride storage was not the only important factor determining endurance during cold stress. Goldfinches do have significant triglyceride reserves in summer, but in the −94° tests, they fail to use these reserves before going hypothermic. Most important, when goldfinches tested at −94° in winter do finally succumb to the cold, they still have considerable triglyceride reserves remaining in the storage depots. The failure to thermoregulate when triglyceride reserves appear adequate may be related to a complex series of hormonal and biochemical factors that influence mobilization, transport, and oxidation of fatty acids.

To understand further the role of fuels in limiting the thermogenic capacities of goldfinches, we turned to an examination of the use of carbohydrates by shivering muscles. Vertebrates normally store only a fraction of their total energy reserves as the carbohydrate glycogen. Glycogen has about one-half as much energy per gram as does triglyceride and, in addition, must be stored

dissolved in water. Triglyceride, in contrast, is hydrophobic and can be stored in an energy-dense form that minimizes its bulk.

Existing data on mammals (including humans) suggest that carbohydrate, although quantitatively less important than triglyceride, is the limiting fuel in conditions requiring a high rate of energy expenditure, such as exercise or cold stress. Although the exact mechanism causing muscle fatigue is not clearly understood, muscle exhaustion correlates with a depletion of glycogen reserves and/or a reduction in blood glucose, which is either derived from liver stores of glycogen or synthesized in the liver from other compounds, principally amino acids. People who jog or run recognize that fatigue sets in long before triglyceride reserves become exhausted; marathon runners usually attempt to prolong their endurance by "carbohydrate loading" before a race. It is also interesting to note that in humans subjected to cold stress, low blood glucose often leads to hypothermia.

Goldfinches captured in winter store approximately 11 to 25 milligrams of glycogen in the pectoralis muscles and liver, an amount representing only about one-hundredth the mass of triglyceride stores. When these birds were tested at moderately and severely cold temperatures, they removed less glucose from the blood and used less glycogen stored in the pectoralis muscles than summer birds tested under similar conditions. The endurance of these birds during cold stress may depend significantly on the ability to utilize the available carbohydrate at a lower rate in winter than in summer. We believe this ability results from an enhanced capacity to catabolize triglyceride in winter: the activity of the enzymes that break down fatty acids is 50 percent higher in the muscles of winter birds than in those of summer birds. The use of more triglyceride in the muscles may spare the limited carbohydrate for such essential functions as energy supply to the brain, which is principally dependent on blood glucose for energy.

Although the augmented capacity to store and use triglyceride and the decreased rate of carbohydrate breakdown appear to play important roles in the seasonal increase in thermogenic capacity in goldfinches, other metabolic factors may exist that we have not yet documented. It is important to remember, too, that these metabolic changes constitute only some of the methods by which goldfinches cope with cold winters. By slight increases in insulation and the use of protected nocturnal roosts, they also reduce the amount of heat production required to maintain body temperatures. William A. Buttemer, another graduate student working with Dawson, found that goldfinches roost among the branches of conifers during winters in southern Michigan. Measurements of the heat production necessary to maintain a high body temperature in these roosts indicate that the birds may conserve as much as 30 percent of the energy that would be required if they roosted in an unprotected spot. The success of goldfinches in cold climates is clearly due to a suite of metabolic, insulative, and behavioral adaptations.

As some features of the goldfinches seasonal adjustment to cold became apparent to us, we wondered whether this pattern was typical of other cardueline species. To address this question, we turned to house finches (*Carpodacus mexicanus*). These 18- to 21-gram birds have a more southerly distribution than goldfinches and are very common in the southwestern United States. Their distribution extends northward up the Pacific Coast and into the Rocky Mountain states. Before the 1940s, house finches did not occur naturally in the eastern United States. Pet dealers in New York, however, illegally transported some house finches from southern California for sale as cage birds and abruptly released them just prior to raids by the authorities; the descendants of these birds have now successfully colonized most of the eastern coastal states.

We were able to detect only a minor seasonal difference in the thermogenic capacity of house finches subjected to −94°. Birds captured in Boulder, Colorado, during the coldest winter on record tolerated below −76° for an average of ninety-eight minutes, whereas birds captured in summer averaged only nine minutes. These results are interesting because of both the low endurance capacities of house finches, particularly in winter, and the lack of a dramatic seasonal increase in their thermogenic capacity, compared with the goldfinch findings. Other important differences between house finches and goldfinches emerged when body masses and constituents were analyzed. House finches exhibit no seasonal fluctuation in either triglyceride content, which remains constant at about one gram, or body mass. Finally, in winter, house finches do not reduce their reliance on blood glucose during exposure to cold.

These findings indicate that house finches lack the characteristics that we believe contribute importantly to the abilities of goldfinches to stay warm in cold climates. How, then, do house finches survive cold winters? Perhaps the large thermogenic capacity in goldfinches represents an ability for prolonged heat production that they exploit fully only under exceptionally severe weather conditions; the lower thermogenic capacity of house finches may signify a smaller margin of safety and may result in substantial mortality during prolonged, severe winter storms. The success and persistence of house finches in the northeastern United States, however, suggests that alternative methods are employed for coping with cold winters. House finches, more than goldfinches, appear to rely on filling their crops with seeds just prior to retiring to their roosts for the night. Perhaps other behavioral and physiological adaptations will be identified. The survival of house finches in cold climates may be enhanced, for instance, by their association with humans, in terms of their use of buildings and houses as nocturnal roosts and their dependence on seeds from feeders.

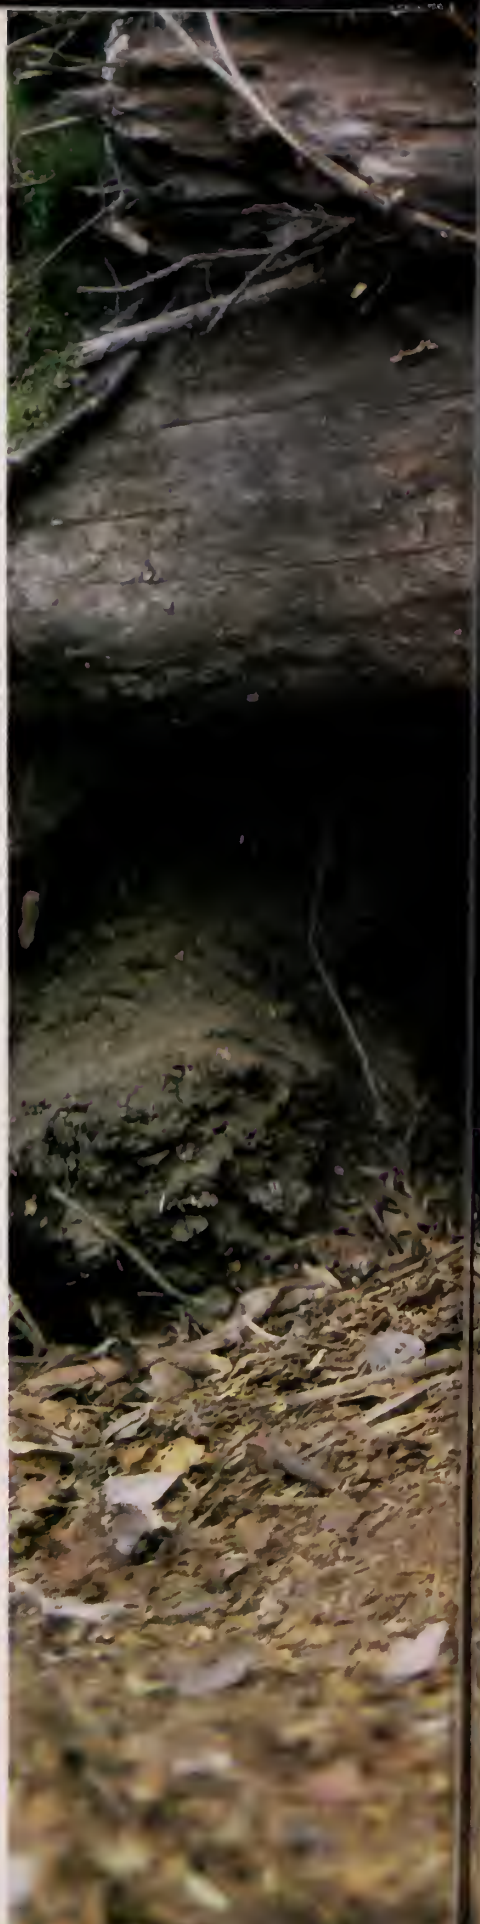
Cold winters provide substantial challenges to small birds, and our research indicates that at least some of the birds respond in ways that make them physiologically and biochemically distinct from their summer counterparts. Further research will undoubtedly uncover additional physiological and behavioral patterns that foster the survival of birds and other organisms in stressful environments. Study of the flight muscles of birds, with their specialization for high oxidative metabolism, can be particularly helpful in understanding the factors that limit the abilities of all animals, including humans, to sustain high rates of metabolism for long periods of time.□

House finches, unlike goldfinches, do not show a marked increase in ability to produce heat in the winter. For them, survival in cold climates may depend partly on seeds from bird feeders.

Laura Riley

A Bear in Its Lair

Although its den provides little protection from the elements of a Minnesota winter, a black bear has a 99 percent chance of seeing spring



by Lynn Rogers

Winter is the season of highest mortality for most northern mammals. But not for black bears, which are masters of winter survival. Their winter death rate of less than one percent is their lowest of the year.

Once considered not true hibernators because of their high body temperatures in winter, black bears are now known to be highly efficient hibernators. They sleep for months without eating, drinking, urinating, or defecating. Hibernators with lower body temperatures, such as chipmunks, woodchucks, and ground squirrels, cannot do this. These other mammals must awaken every few days, raise their temperatures to over 94°F, move around in their burrows, and urinate. Some of them must also eat and defecate during arousals. Black bears, however, develop far more insulative pelts and have lower surface-to-mass ratios than the smaller hibernators. As a result, the bears' body heat is lost very slowly, enabling them to cut their metabolic rate in half and still make it through winter, maintaining temperatures above 88°—within 12 degrees of their normal summer temperature. This, in turn, means that a black bear can react to danger faster than most other hibernators whose body temperatures may be less than 40°. New knowledge of hibernation processes has led biologists to redefine mammalian hibernation as simply a specialized, seasonal reduction of metabolism concurrent with the environmental pressures of food unavailability and low environmental temperatures.

In northeastern Minnesota, where I have studied black bear behavior and ecology since 1969, bears commonly go for seven months without eating—from mid-September until mid-April. To do that and remain in good condition requires changes in physiology, and some of these changes create conditions in bears that would cause problems in people. How bears remain healthy in winter, and how their adaptations may be used to improve human medicine, have recently become subjects of study at some of the leading medical research centers in the country. For example, bears that are living off their fat have cholesterol levels more than twice as high as their summer levels and more than twice as high as the cholesterol levels of most humans. Yet bears have no known problem with hardening of the arteries or with the formation of cholesterol gallstones. Medical studies have shown that bears in winter produce a bile juice, ursodeoxycholic acid, that may help them to avoid problems with gallstones. When given to people, this acid dissolves gallstones, eliminating the need for surgery. Black bears also greatly reduce their kidney function in winter. They do not urinate for months but still do not poison their bodies with waste products such as urea. The urea is somehow broken down and the nitrogen from it is reused to build protein. This ability to build protein while fasting allows the bears to maintain their muscle and organ tissue throughout the winter. They only use up fat. Evidence is accumulating that the physiological changes that occur in hibernating black bears are controlled by hormonelike substances. These substances also produce hibernationlike effects when injected into other species—both other hibernators and nonhibernators, suggesting possible uses in human medicine.

Hibernation for the black bear, as for other mammals, is primarily a mechanism to conserve energy through seasons of no food or water. The process, however, does not work every year. If there is insufficient food in summer, bears lose weight and starve, much as we would. In northeastern Minnesota, summer is practically the only season with enough of the right foods for bears to gain weight. In other seasons, the right foods are either lacking or so scarce that

Lynn Rogers

bears lose weight. Grass, which bears eat in great quantities in the spring, is not easily digestible. Black bears in my study area begin to fatten up for winter in June, with the ripening of carbohydrate-rich berries. The bears' weight gains in summer depend mainly on the availability of good crops of blueberries, cherries, wild sarsaparilla berries, and hazelnuts. When these and other digestible foods disappear in September, energy conservation becomes the rule until the following May or June.

One exception to this rule concerns bears that are miles outside their usual home ranges when food becomes scarce in the fall. They have to expend considerable energy returning home for winter. A 450-pound, eleven-year-old male that was 119 miles from home on October 15 made the trip back in nine nights, going straight to a den. A second way in which black bears expend, rather than conserve, energy in the fall is by preparing a different den each year. Why they do this—often with the den of the previous year still intact—is anybody's guess. In one case, a fifteen-year-old pregnant female with access to two rock caves she had used in previous winters chose in-

Lynn Rogers

stead to build a nest above ground. (In February of the same winter this female and her newborn cubs became the first radio-monitored black bear family to be killed by wolves.)

For their dens, the black bears I observed generally chose burrows, caves, rock crevices, hollow trees, or excavated depressions under fallen trees or brush piles. A few bears simply built nests on the surface of the ground. Hollow trees were uncommon, but seemed to be preferred for dens because they probably provided the best insulation and protection from hunters and predators. Entrances to underground dens or tree cavities faced in all directions—here the bears had no discernible preferences. The entrances usually were just large enough for the occupant to squeeze through, opening into a chamber that was typically two and a half to five feet wide and two to three feet high. The distance from entrance to bear was usually two to five feet, but in some cases as much as fifteen feet.

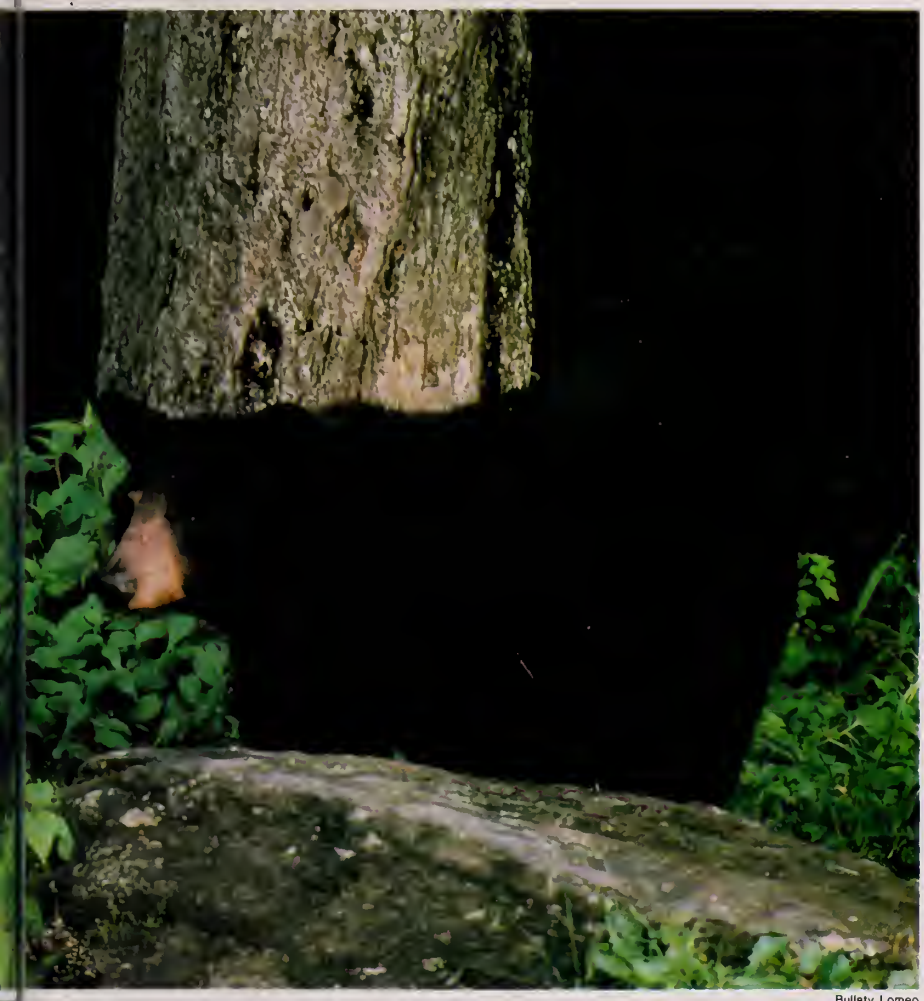
Temperatures in the dens depended on snow cover—the bears, with their low metabolisms, did little to warm the space. In winters with several feet of snow, den entrances were often covered and temperatures inside were only slightly warmer than the soil, a few degrees below freezing. In winters with light snow, den entrances remained open and temperatures in the dens were about the same as that of the outside air, frequently 60° below freezing. Open entrances were more common. Those dens acted as windbreaks, but provided little other insulation.

The main insulation for a bear in winter is its fur, which more than doubles in insulative value during the fall. The fur is thickest on the back, neck, and sides and thinnest on the muzzle, legs, and underside. A hibernating bear sleeps in a curled-up position so that its crown is against the den floor and its nose is near its tail. This position minimizes a bear's surface area and reduces heat loss from the thinly furred areas. For extra insulation, bears sleep on a nest of leaves, grass, and other material that they rake into the den. These nests also insulate cubs from the ground.

Females usually give birth to two or three cubs every two years; cubs are born in January, weigh less than a pound, and have practically no hair at first. After giving birth, the female resumes her deep sleep, waking on occasion to tend to the cubs' needs. She licks them to clean them and to stimulate defecation. She eats their feces and moves into position to facilitate nursing. The cubs do not hibernate. They suckle and sleep snuggled warmly against their mother's sparsely furred underside and reach weights of four to eight pounds by the time they leave the den at three months of age.

Ending her hibernation in mid-April, a black bear emerges from her den with two cubs that were born in January. She will suckle the cubs in the vicinity of the den for a few days, then move to snow-free ground.

Jim Brandenburg



By the time they emerge from their natal dens, black bear cubs weigh from four to eight pounds. As adult females give birth at intervals of two or more years, these cubs, above and right, will remain with their highly protective mothers through the following summer.

The bears under study usually spent considerable time in the fall gathering nest material and arranging it in their dens. Most of them arrived at their den locations well before snow covered the nesting materials, usually in late September or early October. (One arrived on September 2.) After digging a burrow or depression or renovating a rock cave that another bear had used in years past, the bears spent most of their time resting in and around the den or gathering nest material until they entered their dens to stay, usually in late October. Whenever cedar trees were present, bears stripped the fibrous bark from them to use in making nests. The narrow strips of bark, up to several feet long, make a durable bed that does not partially disintegrate and lose insulation value by spring in the way that beds made of finer materials such as leaves, grass, and clubmoss often do. These less sturdy materials were generally the only ones available, however, and so most nests were built with them. A few bears waited until snow covered the ground to start the work of creating a nest, but these were mainly bears that had access to an unusually long-lasting food supply, such as acorns, mountain ash berries, or garbage. They either did not make nests or made them of conifer boughs that they bit from trees.

From September 29 through October 18, 1972, Steve Wilson, Leon Konz, and I worked in shifts around the clock, watching a family of bears settle in for the winter. During the previous week, the animals had completed a burrow under the roots of a fallen pine and with all three cubs (of the previous winter) helping their mother, had begun to rake up bedding from a fifty-foot radius around it. The cubs raked leaves, grass, and forest litter, backing toward the den as they pulled piles of material with their front paws. The five-year-old mother did the same, but in addition, she bit branch tips from willow bushes and pulled up supple Labrador tea plants with her teeth, dropping them on her own piles. She also took charge of arranging all the nest material in the den. The cubs could have done a good job of this, too, as orphaned cubs have demonstrated, but the mother had her own ideas about the nest. Twice she scooped all the material out of the den, sending it flying backward between her hind legs and then putting it back her own way. Except for these vigorous remodeling jobs and instances when the cubs quickly grouped behind their mother after hearing a strange noise, all the actions we saw during this period of den preparation were languid and listless. There was no play. The bears were active only during the day, and during the three weeks of observation the activity decreased from a few hours per day to a few minutes before ceasing altogether.

The activities of these bears followed about the same daily schedule as those of a captive black bear in Alaska whose heart rate Ed Folk of the University of Iowa monitored by telemetry. That bear, too, was active mainly by day as it neared the hibernation period. For most of each day in early fall the bear's heart beat between fifty and ninety times per minute, then for most of each night, while the bear rested, its heart rate slowed to between forty and fifty beats per minute. As fall progressed, the bear began sleeping for more and more of each day. By December, when monitoring ended, its sleeping heart rate had gradually declined to as few as eight beats per minute. This heart rate was as

Bullaty Lomeo

slow or slower than that of most low-temperature hibernators.

Even in hibernation, the captive telemetered bear retained a remnant of its day-active schedule. For a portion of most days, the bear's heart speeded up to more than forty beats per minute, and the animal was wakeful enough to lift its head if the room lights were turned on. Wild bears in northeastern Minnesota also tend to be day active, and most of those I visited in dens were wakeful enough that they lifted their heads and looked at me. Although, in general, they seemed less sensitive to danger than they had been in summer, some were moderately aggressive. A few did not wake up even during several minutes of gentle prodding and jostling, however. In one case, on March 27, 1970, I accidentally fell on a six-year-old female in her den. She didn't wake up for at least eight minutes even though her cub bawled loudly and I began gently prodding her. I wondered if the different receptions I got from the bears reflected differences in their heart rates at the times I happened to visit them. On calm days I could hear the rapid, strong heartbeats of alert bears from the entrances of their dens, but I could not hear the soundly sleeping ones.

On January 8, 1972, I tried to hear the heartbeat of a soundly sleeping five-year-old female by pressing my ear against her chest. I could hear nothing. Either the heart was beating so weakly that I could not hear it or it was beating so slowly I didn't recognize it. After about two minutes, though, I suddenly heard a strong, rapid heartbeat. The bear was waking up. Within a few seconds she lifted her head as I tried to squeeze backward through the den entrance. Outside, I could still hear the heartbeat, which I timed (after checking to make sure it wasn't my own) at approximately 175 beats per minute. This heart rate during arousal is even higher than has been recorded for very active bears.

Research scientists were not the first people to look into a bear den. Indians noted the locations of dens they found in the fall and returned to them in winter to kill the bears for food. They respected bears and had special ceremonies surrounding the killing and eating of them. Members of the Winnebago Bear Clan called the first moon of January the bear moon because it is then that the cubs are born and then that the bears begin to lick their paws. Both observations are accurate. The Indians also believed that mothers washed their newborn cubs with fresh snow. According to a clan saying, snow during the bear moon meant that another cub had been born and that the bears, which had control of the weather, were calling for fresh snow to wash their young. Mothers do lick their newborn cubs, but the use of snow has not been documented in modern times.

Bears commonly lick their paws in late winter and early spring because their calloused foot pads and toe pads flake off during hibernation, and the newly exposed skin is not yet toughened up. Bits of the pads can be found in the feces in spring. Primitive people in northern latitudes around the world believed that bears licked or sucked their paws for sustenance in winter. The Winnebago version of this story is that bears walk on berries all summer, crushing the different kinds into their paws so that in winter they can lick their paws and obtain the essence of the berries.

Another story, which has even been stated as fact in the scientific literature, is that bears eat roughage in the fall to scour the digestive tract and form a plug in the anus. The plug supposedly keeps the bear from eating anything more that fall. Actually, there is an anal plug of feces (along with some bear hairs and bits of nest material), but this forms mainly during, not before, hibernation. Bears continue to make feces during hibernation, even though there is no food intake. Feces are composed not only of indigestible parts of food but also of cells that continually slough off the inside of the digestive tract. By spring, there is quite an accumulation of feces in the colon, and some bears defecate portions of this before emerging. In that case, the feces are deposited in or just outside the entrance to the den, rather than in the nest.

From early fall to late spring most black bears lose between 15 and 30 percent of their body weight. Lactating mothers can lose as much as 40 percent.

Bullaty Lomeo

In northern Minnesota, black bears have from mid-April to mid-September to gain enough weight to carry them through the winter. While hibernating, the bears lose an average of 15 to 30 percent of their body weight; lactating females lose as much as 40 percent.

The mothers that lose the most weight are the ones with the heaviest litters.

Most bears I observed left their dens in mid-April although mothers with undersized cubs sometimes delayed until early May. In years of light snow and early melt, some bears left as early as March 27. In northeastern Minnesota, however, the bears rarely, if ever, came out and wandered around on mild winter days. Somehow the bears were not fooled by springlike conditions before March 27. In one case, during March a fourteen-year-old female had a problem with meltwater running into her den and soaking the nest that she and her two-month-old cubs were sleeping on. She left the den briefly and bit branches off several spruce saplings, bringing them back inside to pile onto the nest and raise the family above water.

For several years Wilson, Konz, and I observed the activities of four family groups day and night as they emerged from their dens in April. They were active only by day, and their activities were much the same in all cases. The mothers began foraging within 150 yards of their dens, leaving their four- to eight-pound cubs in the dens or playing around the entrances. The cubs retreated into the dens at any strange sound, and their mothers returned every ten minutes or less to check on them. The mothers tore apart logs in search of beetles, grubs, and other invertebrates high in protein, climbed aspen trees to eat catkins, ate willow buds and grass, drank meltwater, and in one case consumed a deer carcass we had placed near the den. (Winter-killed carcasses are usually not available to bears in spring because they are cleaned up by wolves, ravens, eagles, and other scavengers before the bears emerge.)

The mothers also spent a lot of time resting in or near their dens. When outside, the cubs were very active, climbing small trees, stumps, or their mothers' backs. Mothers nursed their cubs lying down or sitting up. One mother sometimes sat leaning back against a support, cradling two of her cubs to her chest and licking the tops of their heads as they nursed. After a few days, the mothers moved their families to patches of snow-free ground at the bases of large trees. The ground was still frozen and the surface was wet with meltwater. As all bears do in early spring, the mothers constructed beds to rest on. With trees available for the cubs to escape into, the mothers would leave their cubs for an hour or more.

With all the study of hibernating bears, a basic question remains: How do bears know when to go into or leave their dens? Certainly the bears live by some kind of internal clock, but what sets this clock—day length or some other cue—is unknown. Time of denning and emergence seems to vary to some extent with food supply, weather, and genetics, but how these and other possible factors interrelate is still a puzzle. For the Winnebago Indians the answer was simple: the black bear is a clever and intelligent animal. □

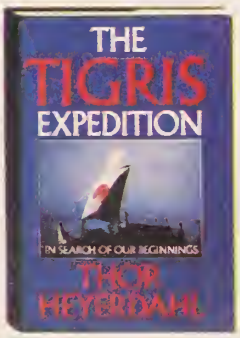
BOOKS THAT ANSWER

Q: Are modern computers as smart as any living animal?

A: Today we have machines with the intelligence of the earwig, a tiny insect. This may not seem much, until you realize it took evolution millions of centuries to make the same leap. (See *The Micro Millennium.*)

Q: Can time speed up and slow down?



A: Yes, by the theory of relativity. Consider two twins. One leaves Earth in a spaceship, travels close to the speed of light, and returns. Although he's only a few weeks older he's astonished to find that Earth has aged hundreds of years. His twin brother, and everyone he knew, is long since gone. (See *Einstein's Universe.*)

Q: Most important brain functions are represented in both the right and left halves. But which vital function is only found on one side?

A: Speech. There are three speech areas in the brain, but in the vast majority of people they are all on the left side. (See *The Origin of Consciousness in the Breakdown of the Bicameral Mind.*)

Q: Is this the only universe?

A: Reasoning from quantum theory, some scientists now believe there may be other universes in addition to our own—perhaps an infinite number of them! All of the universes, including ours, would be embedded in a mind-boggling entity called "superspace." (See *Other Worlds*)

Facts about Membership

You receive the Book-of-the-Month Club/SCIENCE News® 15 times a year (about every 3½ weeks). Each issue reviews a *Main Selection* plus scores of Alternates. If you want the *Main Selection* do nothing. It will be shipped to you automatically. If you want one or more Alternate books—or no book at all—indicate your decision on the reply form always enclosed and return it by the date specified. *Return Privilege:* If the *News* is delayed and you receive the *Main Selection* without having had 10 days to notify us, you may return it for credit at our expense. *Cancellations:* Membership may be discontinued by either you or the Club, at any time after you have purchased 3 additional books.

Black holes twisting space and time like a pretzel—and gobbling down whole planets.

Here on Earth, the stunning adaptability of life: a desert animal that swims through sand the way an eel swims through water. And the ingeniousness of man: a new concept that may generate limitless electricity by duplicating the power of the sun.

And, in each of your cells—a substance called DNA, compressing into an invisibly tiny volume all the information needed to create *you*.

As someone living in an age of unparalleled discovery, you've undoubtedly been curious about things like these.

And you've probably noticed the explosion lately in books about science for people who are not scientists.

But how do you know which are the best?

Let a whole new kind of book club find them for you. Book-of-the-Month Club/SCIENCE.

If you've ever wanted the chance to really explore the wonders of modern science, this is the way. Because now you can be sure you're getting works that are understandable, lively and authoritative.

Book-of-the-Month Club/SCIENCE will lead you to books that indulge your sense of wonder to the fullest, sparkle with discovery, tantalize with new questions.

Books that can change your way of thinking. And the way you and your children live.

We invite you to start by taking any 3 for $1 each.

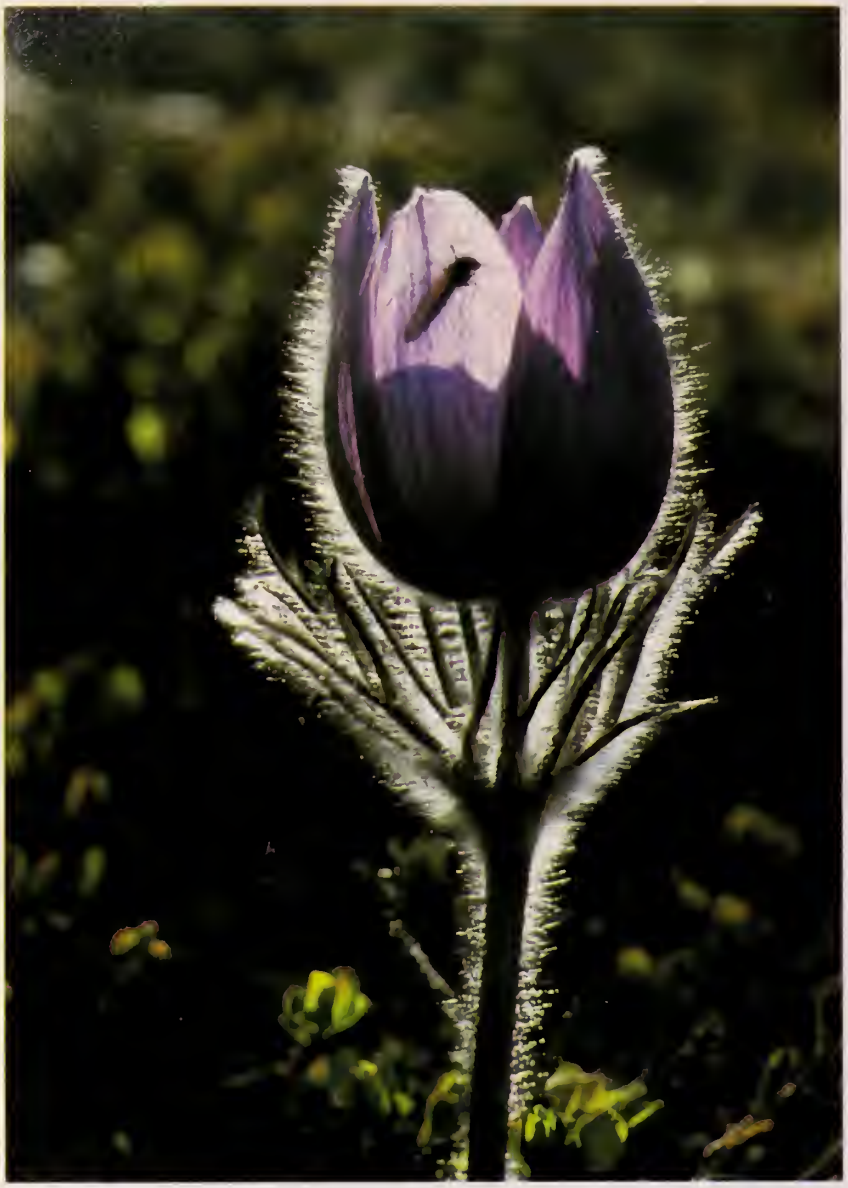
Flowers That Make Heat While the Sun Shines

Some plants that bloom at low temperatures act as solar collectors, hastening the growth of pollen and seeds



by Roger M. Knutson

My first thought at the sight of a bee, fly, beetle, or mosquito scrambling across a sunlit, early spring bloom is that food needs are being met. Therefore, when one of my students on a botany field trip a number of years ago asked me why so many of the early spring flowers in the forests of northeast Iowa were white, I responded that they were easier for potential pollinators to locate. While that may or may not be true, their brilliance certainly makes it easier for people to see them in the low-angled sun that strikes the forest floor before the trees leaf out. The student's question, however, returned to mind in subsequent springs, and as I thought about it, other generalizations about early spring bloomers suggested themselves. Many of the flowers are bowl or saucer shaped; they are often more or less heliotropic, or sun following; they tend to have reflective petals; and they frequently have centers composed of many fuzzy stamens and carpels. I conjectured that many of these flowers might be accumulating heat by behaving like small dish antennas, focusing reflected light and heat on the flower center where reradiation among the stamens and carpels would effectively retain the heat for a time.

That the green leaves of plants use sunlight for photosynthesis has been known since the late eighteenth century, but how flowers might use solar energy for heating is less well understood, possibly because we cannot see the energy that flowers capture. The red and blue colors visible on the edges of every rainbow are essential to the all-important food-making processes in plants, but beyond the blue and red are colors—wavelengths of electromagnetic radiation—

Pasqueflowers Jim Brandenburg

Left: The cup-shaped blossoms of the pasqueflower collect the warmth of the sun. On a sunny morning in early spring, temperatures inside the flowers can be as much as 18 degrees Fahrenheit warmer than the surrounding air.

Rick Furniss, AlaskaPhoto

Below: Poppies in Alaska follow the sun with their highly reflective petals. The heat stored by the flowers' stamens and carpels may accelerate the development of pollen and seeds.

Nancy Simmerman, AlaskaPhoto

that we can detect only by nonvisual means. Ultraviolet wavelengths are shorter than those of blue light and energetic enough to damage living things exposed to them. Fortunately for life on earth, most of the potentially harmful ultraviolet rays are filtered out by a high-altitude layer of ozone. Bees can see some ultraviolet colors that are invisible to us, and some flowers have ultraviolet patterns that are important in pollination relationships.

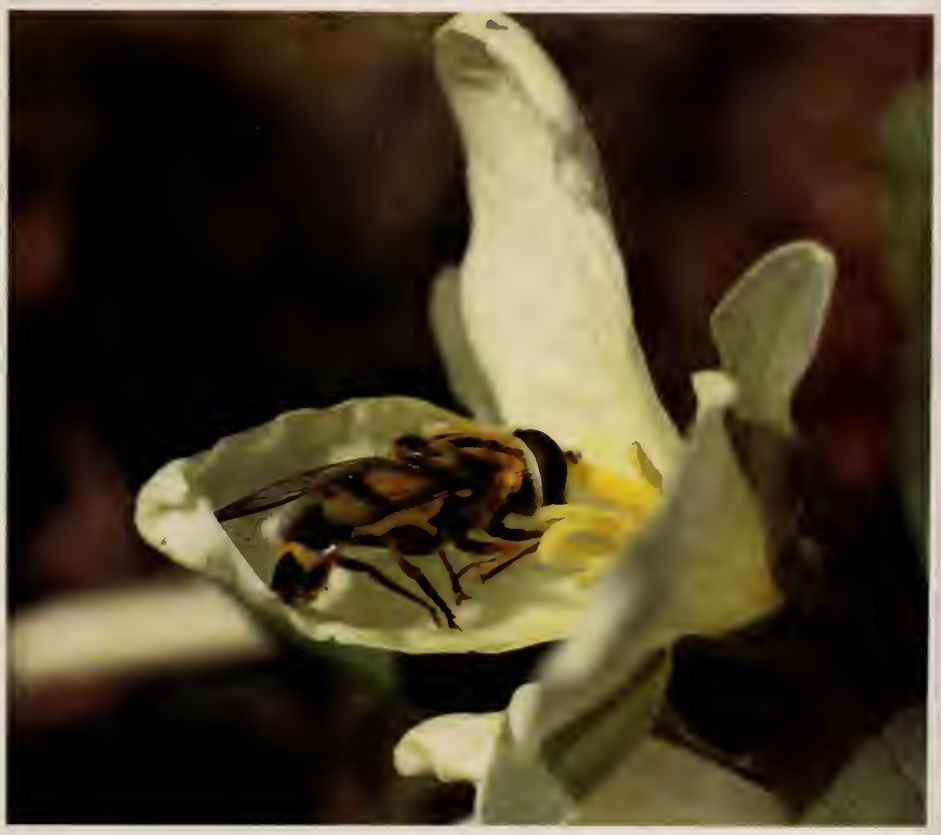
At the other edge of the rainbow, red fades into the long infrared (IR) wavelengths, which we do not see but can feel as heat. Almost half of the total solar energy reaching the surface of the earth is in the IR wavelengths. This energy heats all exposed surfaces, evaporating water and warming plants and animals; although abundantly available to plants, it is not used in photosynthesis. The shorter IR wavelengths are the most energy rich and are received primarily from the sun; longer IR wavelengths, associated with radiant heat of lower temperatures, are radiated from all heated surfaces and are absorbed by nearly all surfaces. A room will feel cold to us if we radiate more heat to the walls than we receive from them.

Much of what is understood about the complex energy environment of plants and animals is due to the work of biophysicist David Gates and his colleagues, who have carefully measured and calculated the amounts of energy of all sorts that enter and leave the earth's

environments and the creatures in them. During daylight hours, about one calorie of energy per square centimeter per minute reaches an exposed leaf at the earth's surface, most of it as short-wavelength IR from the sun. That amount of energy is sufficient to heat objects to a high temperature in a short time. If you have ever touched a piece of metal that has been in the sun or sat down on a car seat that has been illuminated for a while, you are aware of just how much heat can be accumulated.

Leaves and petals are not cooked on the stem because of surface and anatomical properties developed long ago by the earliest land plants. Ninety percent or more of the short-wavelength IR striking the surfaces of leaves and petals is reflected, and if water is available and the microscopic stomatal pores of the leaf are open, nearly all the heat a leaf does absorb is carried away by evaporation, much as a sweating body is cooled by water loss. When evaporation is limited or reduced, a leaf in sunlight can rapidly heat to 18 to 36 degrees Fahrenheit above the air around it. According to Gates, leaves would rapidly heat to fatal temperatures if they did not lose heat by evaporation.

In warm climates or habitats with abundant sunlight the problem faced by land plants was excess heat, but as plants moved into cooler climates, advantages would have accrued to those plants able to warm critical parts with heat-giving IR rays from the sun and to direct this heat to the benefit of reproductive processes. Thinking about my student's question and about Gates's work, I wondered what adaptations for the accumulation of heat might have evolved in arctic, alpine, or cool-season temperate plants.



The earliest plants to bloom in northeast Iowa are the snow trilliums (*Trillium nivale*), which follow the sun well enough to make a brilliant display in late afternoon when the viewer's back is to the sun. Although not particularly circular or dish shaped, the snow trillium does have a deep center and three spreading, bright white petals pointed

Rich Tardiff, amwest

Larry Stone

Above: Snow trillium's bright white petals may make it more visible to pollinators. Some insects seem content to bask in warm flowers without feeding. Left: This marsh marigold is truly an early bloomer. Once the flower is free of the ice, its petals, shaped like a shallow bowl, may help accumulate heat from the low spring sun.

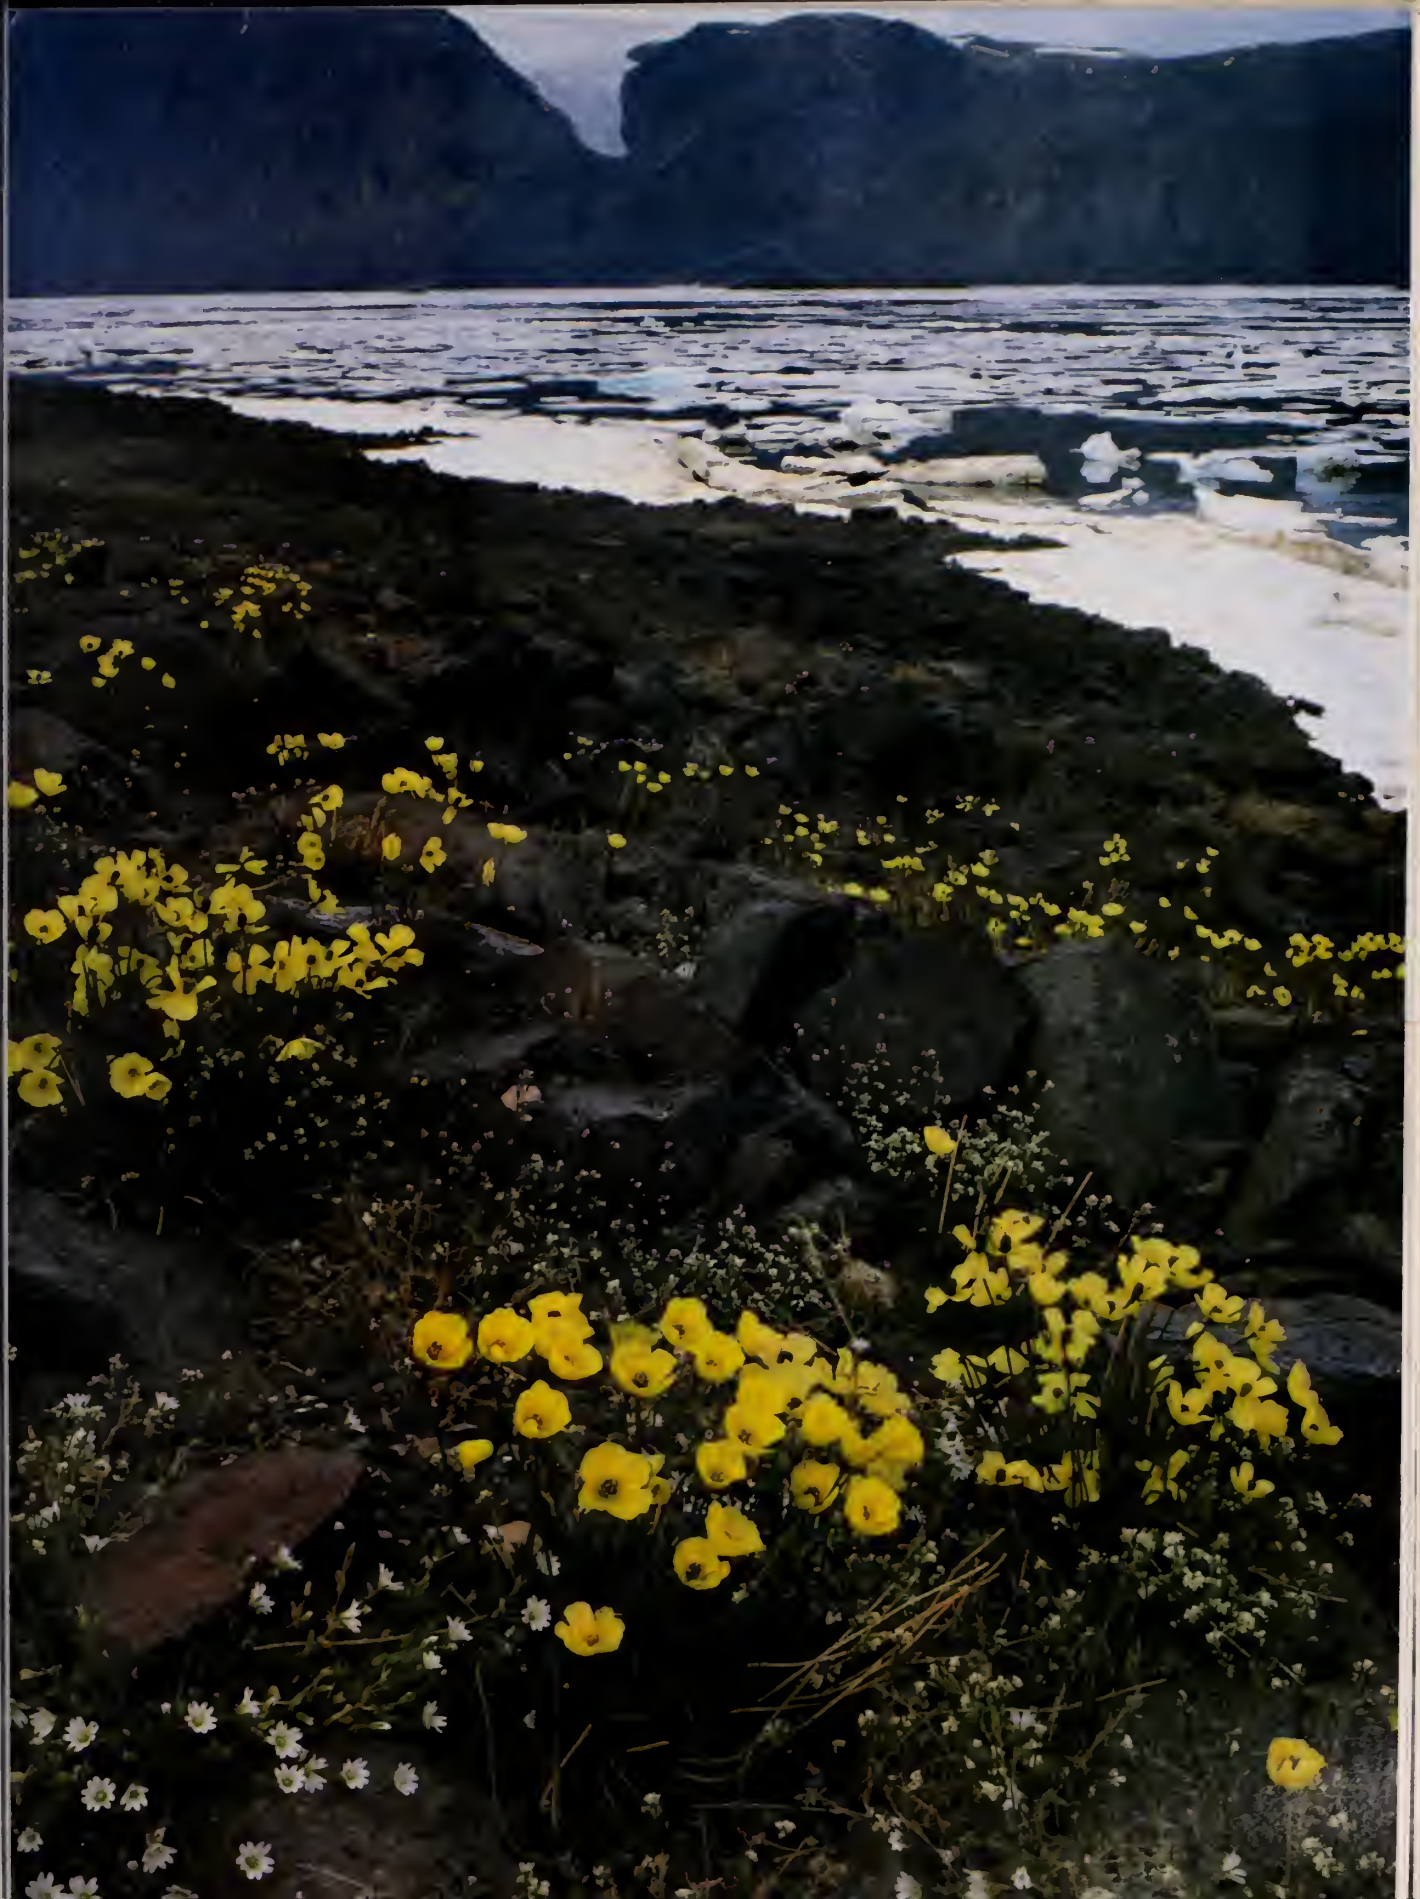
directly at the sun. Using small thermistors, I attempted to measure temperature differences between centers of the trillium flowers and the surrounding air. When the sun was out, the temperature in the flower centers was consistently 4 to 5 degrees warmer than the air; the difference gradually disappeared when the flowers were shaded or when a cloud passed over the sun. Several other early bloomers, such as the hepaticas (*Hepatica* spp.) and the anemones (*Anemone* spp.) are less accurate sun followers, but they have a shallow-dish shape, as well as the extremely shiny upper petal surfaces characteristic of the buttercup family. Unfortunately, the anemones and hepaticas were too small for me to take their temperatures accurately with the equipment I had.

The largest early-blooming flower I was able to examine was, not a forest plant, but the prairie pasqueflower (*Anemone patens*). Its flowers, which have a deep-dish shape, are as much as 1.5 to 2 inches across, follow the sun closely, and contain almost innumerable fuzzy stamens and carpels in their centers. The temperature of the first flower center I examined was an exciting 18 degrees above the near-freezing air of an April morning. When the air was still and the sun constant, most of the pasqueflower blooms I measured were from 14 to 18 degrees warmer than their surroundings, and like the trilliums, these flowers returned to near-ambient temperatures when shaded for a time. Small bees, beetles, or other flying insects were always present in the pasqueflowers. Insects frequently spent the night in the blossoms, which closed with darkness, and even when skies were overcast, many remained completely stationary in the flowers for long periods of time. Very little nectar is present in pasqueflower blooms, and while pollen is abundant, few insects were observed feeding on it or carrying it away with

them. Most of the insects seemed content to bask in the warmth of the sun as magnified by the collection plates of the petals and temporarily stored in the fuzzy center structures. If you are small enough, I thought, Palm Beach is as close as your nearest pasqueflower.

These observations were sufficient stimulus to push me into searching out the published research on flower temperatures, which while most interesting, was very limited. In 1965, Brian Hocking and C.D. Sharplin of the University of Alberta, Canada, had reported on the basking behavior of insects in dryas (*Dryas integrifolia*) and arctic poppy (*Papaver radicatum*) flowers on Ellesmere Island in the Arctic Archipelago. They had measured temperatures of 18 degrees or more above air temperature in the centers of the poppies and suggested that both insect and plant germ-cell development would be accelerated by this solar energy bonus in a climate where small energy advantages might be critical for survival. Following up on Hocking and Sharplin's observations ten years later, Peter Kevan, now of the University of Colorado at Colorado Springs, carefully quantified aspects of flower shape and energy accumulation. He found that both spherical and parabolic shapes would focus heat and light directly on the reproductive parts of the flower. Arctic poppies, Kevan calculated, increase the degree-days available for growth by as much as 25 percent because of their passive solar heating. This means that during the six-week-long growing season in the High Arctic, poppies accumulate the equivalent of seven and a half weeks of heat. To test the hypothesis that insects that stayed in those flowers longer than strictly necessary for feeding would reap similar benefits, he measured the heat that insects accumulated by inserting tiny thermocouples in their thorax. On dryas flowers, insects developed temperatures as much as 32 degrees in excess of air temperature.

If insects can accumulate energy from the heat available in flowers, they may seek out the warm flowers during colder periods. The plants could thus conserve energy by accomplishing pollination while providing less food. Moreover, in cold climates, where heat is more abundant near the ground owing to reradiation of solar input and where selection favors small, low-blooming plants, the evolution of efficient parabolic or spherical solar collectors may make the flowers easier for flying, heat-sensitive insects to locate.



Whether selection in arctic and other cool-to-cold climates has produced collectors or whether those plants already bearing suitable flowers have been more successful in such climates is difficult to determine. The heating of flower centers by radiant energy from the sun may merely be an incidental property of flowers that are bowl shaped for other reasons. If the heating is as important as Kevan suggests, however, then we might expect that selection would operate to produce flowers with deep centers and large, highly reflective petals that are retained for a long time. Petals often have unusual epidermal cells and cutin layers, but whether the reflectivity of arctic or alpine flowers is a result of these characteristics remains to be examined. Meanwhile, as scientists study this little-understood aspect of floral evolution, many flowers of arctic, alpine, and early-spring environments will continue to provide warming ovens that accelerate the development of pollen and seeds and probably also aid the survival and speed the reproduction of visiting insects. □

James N. Skeen

Left: Like many plants that flower in the early spring, these rue anemones begin to develop their fruit while temperatures are still cool. Right: On Ellesmere Island in the Arctic Ocean, arctic poppies bloom next to an ice-strewn fiord. Passive solar heating enables these High Arctic blossoms to accumulate the equivalent of seven and a half weeks of heat in a six-week-long growing season.

Martha Cooper

Plants in High Places

From the high equatorial mountains to the arctic tundra, plants must grow rapidly and reproduce in the cold. How do they do it?

by William Dwight Billings

It is mid-July in the Medicine Bow Mountains of Wyoming, but the temperature is well below freezing and the wind-blasted snow rattles on the back of my parka. One doesn't face into that summer blizzard. Underfoot, the moss campion flowers are pink; snow catches in the cushion of small leaves and is then blown over the 11,000-foot ridge, adding to the snowdrift on the lee side.

It is mid-July at Cape Sparbo, Devon Island, in the High Arctic of Canada. The cold northeast wind is blowing a mixture of snow and cold rain off the sea ice of Jones Sound. The low arctic plants catch the wet snow, but the familiar pink flowers of moss campion at my feet are not yet covered.

These two places are 2,500 miles apart, as the arctic tern flies. The alpine, or mountain, location is at latitude 41°21′ north; the arctic one is at sea level at latitude 75°33′ north, only 950 miles from the North Pole. How can the moss campion (*Silene acaulis*, in the pink family) grow and reproduce so well in two places so far apart in latitude and elevation?

The moss campion, which also grows in Lapland, the Alps, and on Mount Washington, is not the only species that shows a widely disjunct distribution between arctic and alpine places. Of the approximately 1,000 species of flowering plants that live and reproduce in the Arctic, more than half also live on high mountain crests to the south. Are such widely separated places alike in their environments? Were their sites easy for certain kinds of plants to get to? Very few of these species, however, reach the high equatorial mountains and fewer still cross the Equator into the colder parts of the Southern Hemisphere. What are the barriers, in space and time, to the migration of plants?

Estimating the amounts of glacial ice and open land available to plants beyond or above timberline is difficult. At times during the last 25,000 years of the Pleistocene Epoch, glacial ice covered as much as 30 percent of the earth's land area, compared with the present 12 percent; there have also been times when glaciers occupied a much smaller area. At present, of the earth's approximately 57 million square miles of land and glacial ice surface above sea level, about 13 million square miles are too cold for the growth of trees. Of these 13 million square miles, approximately 6.8 million are glacial ice: more than 5.3 million are in Antarctica; about 1.1 million are in Greenland and in smaller arctic icecaps; and alpine glaciers outside the Arctic and Antarctica may occupy 400,000 square miles. The total ice-free land between the glaciers and timberline is about 6.2 million square miles: an estimated 2.3 million square miles are in the Arctic; the remainder consists of about 3.8 million square miles of alpine country in the middle latitudes and less than 100,000 square miles in Antarctica.

Only 0.4 percent of the earth's known vascular plant species occur in the cold 3.9 percent of the earth's land surface that is ice-free in the Arctic. Comparisons of the floristic richness (the number of species per unit of land area) in three areas of approximately the same size (about 24,000 square miles) in arctic, temperate, and tropical latitudes reveal a striking arctic-to-tropics gradient. Peary Land, in northern Greenland, has no more than 100 species of vascular plants; West Virginia has 2,126 species; Costa Rica has at least 9,000. Colder climates clearly support far fewer kinds of plants. In addition, arctic plants belong mainly to families that are not common in Costa Rica, whereas except for such wide-ranging families as the grasses, sedges, and composites, the principal plant families of Costa Rica are absent, or almost so, from the Arctic. The ability to grow and reproduce under the stress of low temperatures is critical to survival in arctic and alpine environments, and in spite of the genetic diversity in large families, there seems to be a tendency for low-temperature metabolism to be either present throughout an entire family or almost completely absent.

But apart from the cold, how similar is the environment in the Arctic to that on high mountains? Certain factors, such as cold nights during the growing season, are more influential in alpine areas than in the Arctic. Other factors important in the Arctic are lacking in alpine areas: continuous daylight for weeks or months, for example, and very cold soils due to permafrost. Furthermore, alpine locations in the tropics have less snow, more ultraviolet irradiation, and a longer (year-round) growing season than those of temperate regions. The relative environmental impacts of many such physical factors vary along latitudinal and elevational arctic-alpine gradients. Only one factor does not change much: the daily mean temperature during the growing season. No matter how cold the winter, how deep the snow, or how brilliant the sun, arctic and alpine plants must metabolize, grow, and reproduce at a consistently cold growing-season air temperature.

Ecologists working to decipher how arctic and alpine species evolve tolerances to such extreme environments

A summer thunderstorm forms over alpine tundra in Wyoming's Beartooth Mountains. Half of the alpine plant species that thrive there, watered by such storms and melting snowdrifts, also grow in the Arctic.

William Dwight Billings

Arctic and alpine ecotypes of the same species are often quite distinct. This alpine sorrel in the Wyoming Rockies cannot photosynthesize as fast at low temperatures as a plant of the same species in the Arctic.

William Dwight Billings

have found the concept of the ecotype to be very useful. In 1922, Swedish botanist Göte Turesson found that within widely distributed plant species, certain local populations evolved tolerances to different kinds of environments. When grown together in his garden under uniform conditions, these populations, which he called ecotypes, maintained their distinctive appearance and flowering characteristics. Genetically distinct entities adapted to a given type of environment within the range of a species, ecotypes may be evolutionary dead ends or, by isolation through time, they may become species in their own right.

In the last twenty-five years, studies of the physiological traits of arctic and alpine species and their ecotypes have produced the greatest advances in efforts to understand plant adaptations to cold-summer climates. For more than twenty years, a number of researchers, including H.A. Mooney of Stanford University, M.M. Caldwell of Utah State University, B.F. Chabot of Cornell University, P.G. Godfrey of the University of Massachusetts, and I have been working with alpine sorrel (*Oxyria digyna*), a widely distributed, but not abundant, arctic-alpine species. In ecotypes of this species, photosynthesis and flowering are closely tied to temperature and to intensity and duration of sunlight. The arctic ecotypes are quite distinct from the alpine ecotypes in form and structure (for example, the usually horizontal underground stems called rhizomes are present in all arctic populations and absent from western American alpine populations), but I shall concentrate here on just a few of the physiological adaptations we have found. These principally involve the ways in which certain plant processes are affected by solar radiation and temperature.

Almost all arctic and alpine plants are perennial and take two or more years after seed germination to reach flowering age. *Oxyria* is no exception. After growing very slowly for two or three years, many of these plants produce, at ground level, a bud containing preformed floral initials that overwinter and bloom very soon after the following summer's thaw. In *Oxyria,* the breaking of dormancy in such flower buds depends primarily on two developments: first, the bud temperature must rise above freezing, and second, day length must have reached the maximum number of hours attainable at the latitude at which the population grows. *Oxyria* plants in the Medicine Bow Mountains of Wyoming won't bloom until day length has reached fifteen hours and those in the Olympic Mountains of Washington (latitude 48° north) must have a sixteen-hour day, while alpine sorrel on the North Slope of Alaska (latitude 71° north) or at the same latitude in Lapland requires the continuous daylight of an arctic summer. At arctic latitudes, however, optimum day length comes before thaw and lasts long after it. Hence *Oxyria* plants there wait until July to bloom, even though by that time the sun has been continuously above the horizon for several weeks.

Another way that sunlight particularly affects alpine plants involves ultraviolet B radiation, the shortest wavelengths of solar ultraviolet light that can penetrate the atmosphere and reach the earth's surface. High mountains have less atmosphere above them, so the amount of such ultraviolet radiation reaching alpine plants is more than that reaching the leaves of plants at sea level. Also, stratospheric ozone, which is somewhat of a shield against ultraviolet B radiation, is much thinner and less dense over equatorial regions than over polar regions; thus, high mountains in the tropic and even in the temperate zones receive much more ultraviolet radiation than does the Arctic. Caldwell found that relatively little ultraviolet radiation gets through the leaf epidermis of alpine *Oxyria* and several other species of alpine plants and that a bit more penetrates the leaf epidermis of arctic *Oxyria* plants. He also measured greater epidermal transmission of ultraviolet radiation in green *Oxyria* leaves than in leaves that the pigment anthocyanin had turned purple or red. The anthocyanin acts as a screen against penetration of ultraviolet to the photosynthetic tissues of the leaf. Caldwell discovered experimentally that ultraviolet injury to the leaves of some alpine plants, including *Oxyria*, can be reversed by exposure to certain wavelengths of visible light. The absence of visible ultraviolet damage in nature probably means that under normal alpine conditions such photorepair mechanisms are constantly at work. Early in the season, for example, when ultraviolet irradiance is high and many kinds of plants emerging from melting snow are whitish due to a lack of chlorophyll, young shoots often develop a bright red color as they synthesize anthocyanin from sugars stored in the roots from the previous summer. Some alpine plants, however, produce little or no anthocyanin in the leaves. In such cases, the ultraviolet is usually absorbed by other, colorless compounds and/or is reflected, as Caldwell and his colleagues found in

the silversword plant (*Argyroxiphium sandwicense*) on the volcano Haleakala in Hawaii.

Each growing season, alpine and arctic plants must quickly produce green leaves capable of fast rates of photosynthesis. We have measured, both in the field and under controlled conditions, net photosynthetic rates of *Oxyria* from many arctic and alpine populations across a wide span of temperatures, from near freezing to as high as 113°F. Almost universally, arctic ecotypes had higher rates of photosynthesis than did alpine ecotypes, and rates were highest in plants grown at the lowest temperatures. *Oxyria* plants grown at the highest temperature, on the other hand, could carry on photosynthesis at higher temperatures than plants of the same ecotypes grown at lower temperatures. Alpine ecotypes can acclimate to temperature changes more quickly and precisely than can arctic ecotypes, which indicates that photosynthetic acclimation is under genetic control. In alpine regions, where temperatures near the ground fluctuate rapidly with changes in sunlight and wind, a plant capable of quickly adjusting its photosynthetic system to fit the moment would be at an advantage. Temperatures in the Arctic are more steady and predictable, so an acclimation mechanism would be of less benefit there.

As plants carry on photosynthesis, starch grains accumulate in the chloroplasts. During the night, this starch is converted to sugar, which is moved out of the leaf chloroplasts into the stem and roots. Chabot found that even during the cold nights characteristic of an alpine summer, chloroplasts in *Oxyria* plants from the Sierra Nevada could make this conversion of starch to sugar. In contrast, chloroplasts in leaves of *Encelia virginensis*, a desert shrub species that grows a bit farther down the east slope of the Sierra, could not convert starch to sugar if subjected to these same cold nights. After only a few days and nights, the accumulated starch broke up the *Encelia* chloroplasts, thereby damaging the photosynthetic system.

All arctic and alpine plants are adapted to metabolizing and reproducing at low temperatures. The local vegetational patterns that are particularly characteristic of alpine regions, however, are caused by other aspects of the environment. These factors could be persistent snowdrifts, rock types, nutrients, or water availability. For example, the upper windward side and ridgetop of a slope lose water because strong winds blow their snow into drifts on the lee side. These snowbanks last well into the summer and supply snow meltwater to moist meadows and wet bogs lower down the slope. The local distribution of alpine species is closely related to this type of soil moisture gradient. Some species are present in all parts of the gradient except under snowbanks that melt very late or that melt completely only in unusually warm and dry summers; those places are bare. Most species, however, exist only in certain parts of the moisture gradients: dry ridgetops, moist meadows, or wet bogs. Thus the use of water by these plants or their resistance to drought is as important to their survival as their ability to grow in a cold environment.

When sufficient water is not available to alpine plants, metabolism slows down markedly in some species but not so much in others that are adapted to getting along with less water during dry periods or in drier sites. Steven Oberbauer and I studied water use by plants along an alpine moisture gradient in the Medicine Bow Mountains of Wyoming and found that each species is unique with regard to water intake, retention or loss of water, and tolerance to water loss from leaves. On the dry ridge, shallow-rooted species tend to be conservative in water use; deep-rooted species, such as moss campion and Parry's clover (*Trifolium parryi*), may use and lose more water by obtaining it from deeper in the soil. Wet-meadow plants, in contrast, tend to lose considerable water.

Oxyria differs from most other plants in its water use, having little or no ability to hold water or withstand drought. In the mountains throughout western North America, the species is confined to rocky places below or near snowbanks. *Oxyria* roots must have a good, reliable source of water because its leaves lose water easily, and it will continue to lose water every day until the water source dries up. Not surprisingly, *Oxyria* never becomes established in drought-susceptible places; on the other hand, it is a poor competitor in the densely vegetated wet meadows. This is one reason *Oxyria* is so site-specific, is not abundant, and seldom grows with other plants along the topographic moisture gradient.

Another factor determining local distribution of plant species in alpine and arctic locations is the ability to obtain and utilize certain mineral nutrients in places where such nutrients are in short supply. Nitrogen and phosphorus, for example, tend to be the nutrients least available in cold soils. More is known about the nutrient requirements of plants in arctic tundra, where the cold soils over permafrost are low in nutrients, than in alpine regions. Most of our knowledge in this regard is due to the work of F. Stuart Chapin III, and his colleagues at the University of Alaska, on the availability and absorption of phosphorus by water sedge (*Carex aquatilis*), a widespread arctic-alpine species that occurs from the High Arctic to the southern Rocky Mountains. Chapin has studied the relation of phosphorus to this species along a latitudinal gradient extending from Point Barrow, Alaska, to the high mountains of central Colorado. In each of five locations, he found that water sedge was restricted to colder soils than those occupied by other sedge species. Under standard laboratory conditions, water sedge ecotypes collected from the coldest, most phosphate-deficient soils demonstrated higher phosphate absorption rates than did ecotypes from more favorable sites. This compensation in absorption rates, Chapin concludes, is primarily a response to phosphate availability rather than to soil temperature.

Many of the factors that influence distribution also affect the different methods of reproduction found in cold-climate plants. In general, there is a latitudinal gradient from alpine regions, where reproduction by seeds is the common method, to cold, wet arctic tundras, where only a few species produce seeds regularly and the dominant plants reproduce vegetatively. This appears to be a reflection of the warmer microclimates and drier conditions in the high mountains of the middle latitudes and tropics. The flat, cold tundras of the north are not favorable—in temperature, length of growing season, or nutrients—to the production of seeds. In the Arctic, even those species that do reproduce by seeds take several years longer to reach the seed-producing stage than the same species farther south.

In the wet tundras, most species of grasses and sedges reproduce vegetatively, by rhizomes. Water sedge, for example, and most of the grasses and sedges associated with it in the tundra near Point Barrow produce seeds only rarely. Some sedges and grasses at Bar-

row do reproduce by seeds, but these are usually successional species that invade the drained basins of shallow lakes. Within twenty-five to fifty years, these pioneers are replaced by other grass and sedge species, which produce seeds only occasionally but which, once established, can reproduce by rhizomes to form round clonal colonies. These single-genotype colonies eventually outcompete the pioneers and meet each other head-on.

Water sedge, the ultimate competitor in cold, nutrient-poor tundras, produces seeds so rarely that it enters lake-bottom succession later than the other species, but its slow-growing, long-lived rhizomes and its phosphate-absorbing ability enable it to dominate eventually. The other species are not eliminated; they simply must live with *Carex aquatilis* and share less of the space and nutrients.

Reproduction by stolons (horizontal stems growing above the ground) and bulbils (small bulbs on flower stalks or in leaf axils) is a form of vegetative reproduction in the tundra confined mostly, but not entirely, to small dicotyledonous plants. Two species of saxifrage, nodding saxifrage (*Saxifraga cernua*) and spider saxifrage (*S. flagellaris*), are good examples. While it can produce flowers and seeds, nodding saxifrage reproduces year after year primarily by bulbils in the axils of the leaves. Spider saxifrage can also produce flowers and seeds—but only once. As it flowers and produces new genotypes with its seeds, this species also sends out stolons, just as a strawberry does, with little plantlets on the ends. Since these plantlets on the ends of the stolons are genetically identical to the mother plant, which then dies, the successful genotype is replicated at the same time that sexual reproduction is producing new genotypes and increasing genetic diversity in the population.

The seeds of sexually reproducing arctic and alpine plants may be dispersed by wind, birds, or mammals. Most of the seeds are small. Some have tufts of hairs, others are hairless and shiny, and still others, such as those of *Oxyria*, have small wings. The wind is capable of pushing the seeds over the hard snow for long distances, and migratory birds may carry them even farther. Peter Raven of the Missouri Botanical Garden has suggested that the New Zealand alpine flora evolved, in part, from seeds carried by the stormy westerly winds from the mountains of Australia and even from Patagonia. Long-distance dispersal by birds is very difficult to prove, but there is abundant evidence from the distribution patterns of certain species of birds and plants to suggest that such dispersal is frequent enough to account for some wide distributions, particularly bipolar ones.

In considerations of the dispersal of arctic and alpine plants, the importance of the comings and goings of the great continental ice sheets cannot be overestimated. When the continental glaciers advanced, arctic species moved slowly southward, forming a band of tundra across the northern plains of North America as their seeds were dispersed in front of the ice. Brainerd Mears, Jr., of the University of Wyoming has recently shown excellent geologic evidence that the present grasslands of Wyoming were tundra during full glacial times.

Long mountain systems, such as the North and South American cordillera (consisting principally of the Rocky Mountains and the Andes), provide excellent pathways between the Arctic and the subantarctic region of Patagonia. During the Pleistocene, the continuing growth in elevation of large mountain ranges was crucial to the evolution and spread of cold-climate plants. When mountains reach sufficient height, they offer the challenge of open lands to those upward-migrating species that have enough genetic diversity to establish successful populations above timberline. Once in an alpine situation, a species can adapt by ecotype formation and, with the aid of wind or birds, "island hop" along a mountain chain, jumping from peak to peak. Along the cordillera in the Northern Hemisphere, alpine species moved southward during glacial periods and northward during interglacials.

The genus *Saxifraga* shows an intriguing distribution of arctic and alpine species. More than 300 species exist in the Northern Hemisphere; only one of these, tufted saxifrage (*Saxifraga cespitosa*), extends into the Southern Hemisphere. Juliana Mulroy of Denison University has studied the ecology of plants of the *S. cespitosa* complex from the High Arctic down the cordillera to Tierra del Fuego. The species extends from the Arctic down the Rocky Mountains to San Francisco Peaks, Arizona. Although not common anywhere along this route, *S. cespitosa* can be found here and there on some isolated peaks and ranges. Then, after a 4,000-mile gap

Fred Bruemmer

Tufted saxifrage grows from the High Arctic down the Rockies to Arizona and along the Andes from Ecuador to Cape Horn. Long ago, migrating birds may have dispersed its seeds from Alaska as far south as Argentina.

PAY TO THE ORDER OF Save the Children 19

Sixteen and no/100 $16.00 DOLLARS

(Signature) _____

MEMO: *U.S. Income Tax Deductible Monthly Sponsorship*

(Your Address) _____

City & State _____ Zip _____

Fill out this check (or use your own) and save the children

For only 52¢ a day (just $16 a month) you can befriend a needy child through Save the Children. Your money, combined with that of other sponsors, can breathe new life into an impoverished village…help hardworking people in their fight for dignity…turn despair into hope for a child who has known only disaster. 52¢ may not buy much where you live. But for the poorest of the poor, where the need is so desperate, it can work miracles.

For your first monthly sponsorship contribution, just fill out and sign the check at the top of this page (yes, as long as you indicate your bank name and account number, it is negotiable). Mail the entire page to Save the Children. Of course, you may use your personal check if you prefer.

TELL US HOW YOU WANT TO HELP BY ANSWERING THESE QUESTIONS.

Your name _____ (please print)

Address _____

City _____ State _____ Zip _____

1 What kind of child would you like to help?
☐ Boy ☐ Girl ☐ Either

2 What geographical area are you interested in?
Urgent need exists in all the areas listed below. Select an area, or let us assign a child where the need is greatest.

☐ **Where the need is greatest**
☐ Africa
☐ American Indian
☐ Bangladesh
☐ Chicano (U.S.)
☐ Colombia
☐ Dominican Republic
☐ Honduras
☐ Indonesia
☐ Inner Cities (U.S.)
☐ Israel
☐ Lebanon
☐ Mediterranean
☐ Mexico
☐ Nepal
☐ Southern States (U.S.)
☐ Sri Lanka (Ceylon)

3 Would you like a picture of your sponsored child?
Shortly after we select a child for you, we can send you a photograph and brief personal history, if you desire.
☐ Yes ☐ No

4 Would you like to correspond with the child you sponsor?
If you wish to write to your sponsored child, Save the Children will deliver your letter and make sure you receive a reply, supplying translations if necessary.
☐ Yes ☐ No

5 Would you like information about the child's community?
When you become a sponsor, your funds are used to help children in the most effective way possible—by helping the entire community with projects and services. For health care, education, food production, and nutrition. Several times a year you can receive detailed reports on these community activities which provide permanent improvements to the child's environment. Would you like to receive such information?
☐ Yes ☐ No

6 Do you wish verification of Save the Children credentials?
Save the Children is indeed proud of the handling of its funds. Based on last year's audit, an exceptionally large percentage (83.5%) of each dollar spent was used for program services and direct aid to children and their communities. Due to volunteered labor and materials, your donation provides your sponsored child with benefits worth many times your total gift. Would you like to receive an informative Annual Report (including a summary financial statement)?
☐ Yes ☐ No
(A complete audit statement is available upon request.)

7 Would you rather make a contribution than become a sponsor at this time?
☐ Yes, enclosed is my contribution of $_____.
☐ Check here for general information about our unique programs for aiding impoverished children.

Moss campion roots get moisture from deep in the soil. Water availability and a plant's ability to obtain it or get along with less are two of the factors that influence vegetation patterns in alpine and arctic areas.

Martin W Grosnick, AlaskaPhoto

in its distribution—from San Francisco Peaks to the high volcanoes of Ecuador—the species extends southward down the Andes to Cape Horn. Mulroy found that the South American form, which has been called *S. magellanica*, differs little from *S. cespitosa* of the Northern Hemisphere. She suggests that some of the species' extension down the Rocky Mountains could have been the result of island-hopping by birds and that other, shorter movements could have taken place during full glacials. But the long gap from Arizona to the equatorial mountains and the presence of *S. cespitosa* throughout the alpine and subantarctic regions of South America south of the Equator make it almost impossible not to accept one or more events of long-distance dispersal by birds. Mulroy suggests that alpine Peru may have been the site of *S. cespitosa*'s original introduction to South America, but since some of the wading birds near Point Barrow, Alaska, fly to Argentina for the Southern Hemisphere summer, there is also the possibility that *Saxifraga* seeds could have been carried there and that the species has since moved northward along the Andes. Since the Southern Hemisphere *S. cespitosa* plants differ in small ways from those of the Northern Hemisphere, any long-distance dispersal probably occurred some time ago, but there is nothing to prevent such an event from taking place now.

Studies of present-day distributions of various arctic and alpine species have led to a greater understanding of general biogeographical patterns for cold-climate plants. Most of the ancestors of today's alpine plants appear to have been desert and grassland species that migrated and evolved "up-mountain," especially during the Pleistocene, a period of mountain-building. There is a tendency for alpine floras to show much endemism, that is, to be unique to a given mountain range or mountain system. Once a species has adapted to its particular kind of fluctuating cold environment, there seems to be little back-migration down the mountain to the drier or more forested environments. For these cold-adapted, light-requiring, but not drought-resistant species, migrating to other high mountain ranges or the Arctic is easier. Once in the Arctic, becoming circumpolar or almost so is also relatively easy. Under the right climatic and topographic situations, some of these circumpolar species migrate southward again on the mountains of entirely different continents. Lack of fossils always makes it difficult to say where a given widespread species originated; finding out, by experiment, why and how the species maintains itself where it is currently found is much simpler. Nevertheless, my feeling is that *Oxyria* originated in the subalpine regions of the mountains of southwestern China, where its only closely related relative occurs.

Certainly, many other arctic-alpine species originated in the same way, by migrating up the mountain ranges of Eurasia or North America. There are some truly arctic species in unique arctic environments, but determining how most of these species originated is difficult. The Arctic has had many changes in climate, and at times parts of it may have had a forest cover. A good portion of the endemic arctic vascular plant flora may have evolved in place as climates changed and forest cover retreated southward, but at this time, we can only hypothesize. □

With Pride and Pleasure the Musical Heritage Society offers

The Finest Violin Concerto Recording of this Generation For Just $1

The Tchaikovsky Concerto in D Major

Igor Oistrakh, Soloist
David Oistrakh, Conductor
The Moscow Philharmonic Orchestra

The Tchaikovsky Violin Concerto might well be called the Crown Jewel of romanticism. Brilliant, moving, demanding, and richly orchestrated, it remains among the most popular concertos to this day and a worthy representative of romantic musical literature.

This interpretation (record MHS 4049, cassette MHC 6049) raises the level of beauty, emotional intensity, virtuosity, invention and taste of this work to never-before-achieved heights. David Oistrakh, the conductor, himself one of the greatest violinists of the 20th century is in this recording surpassed by his son Igor, who plays under his father's direction.

The orchestra, the conductor, and the soloist combine to produce, a sound, a mood and ensemble balance so exquisite as to defy description. IT MUST BE HEARD and when heard generates a pleasure and excitement, emotional, intellectual, and even physical. Society members say it is among their most cherished recordings.

We offer the Tchaikovsky Concerto as a sample of the truly superb quality of our records and cassettes.

FREE-NO OBLIGATION MEMBERSHIP

Now you can have this record for just $1, or cassette for $2, together with an absolutely free no-obligation-to-buy-anything-ever membership in the Musical Heritage Society.

When the Society receives your request for this trial record or cassette, we will activate a membership account in your name, and, along with your introductory recording, will include "Selections from Our Master Catalog" containing records and cassettes covering every musical period, carefully chosen from our collection of almost 3,000 records and cassettes.

•The first issue of your FREE, one-year MUSICAL HERITAGE REVIEW subscription will be mailed to you. Published every 3 weeks, the Review is authoritative, lively, and will inform and enhance your enjoyment of classical music.

•Outstanding selections will be scheduled for shipment to you in record or cassette format, whichever you prefer (see bottom of coupon) from each issue of the Review--but there is NO OBLIGATION to accept them. A special response form is enclosed with each Review...and you may use it to order or reject any selections simply by mailing it by the date specified. If you want only the scheduled selections, you need do nothing--they will be shipped to you automatically. You'll have at least 10 days in which to make your decision--If you ever have less time than that, just return the special selections at our expense, for full credit.

•You can avail yourself of the opportunity to purchase Musical Heritage Society recordings at your special member price of $4.95 per LP or cassette, plus postage and handling (deluxe-boxed editions and digital recordings are slightly higher).

Clothing for Cold Climes

Will synthetics duplicate the insulating properties of natural fibers?

by John V. E. Hansen

Considering the many functions we expect it to perform, the design of the body can hardly be faulted. In one area alone—the regulation of temperature—the body provides engineers and physiologists with a unique system for studying a remarkably successful combination of materials and mechanisms that maintains temperature stability within the limits necessary for human survival. This is all the more impressive given the variation in the amount of energy that must be dissipated by the body. A resting human has a metabolic level, or work rate, on the order of 350 BTUs per hour, which must be dissipated to avoid heat buildup. (BTU stands for British thermal unit; one BTU is equal to the amount of heat required to raise the temperature of one pound of water by one degree Fahrenheit.) When an individual walks, the work rate goes up to approximately 900 BTUs per hour, and a very rapid walk up a slight incline would raise the work rate to approximately 1,200. The work rate of an athlete competing in a long race would be in excess of 5,000 BTUs per hour.

Because the body does not dissipate heat in a uniform fashion, it can accommodate a wide range of heat loads. A closer look at the body reveals an ingenious array of flow controls and heat-transfer mechanisms that accommodate this tremendous range in energy dissipation requirements. These mechanisms are worth examining because they hold the clues to the manner in which we can keep ourselves warm. In other words, if we know how the body controls its heat system, we can probably choose clothing materials and designs that will complement these controls and protect the body beyond its own natural limits.

The extremities play a large role in the several mechanisms by which the body dissipates heat. Human limbs and fingers represent an interesting compromise between carrying out necessary mechanical body functions and at the same time presenting a fairly large area through which heat can be released. Heat is removed from the skin surface by means of four processes: evaporation, convection, conduction, and radiation. Of these, evaporation through the pores of the skin plays a major role when there is a large amount of heat to be removed. The normal evaporation of the body's perspiration can be accelerated by replacing moist air near the skin with drier air. The extent of the resultant evaporative cooling is easily demonstrated. A swimmer leaving the water on a day when there is even a faint breeze will quickly feel chilled.

The evaporation effect, of course, works best when the surrounding air is relatively dry and there is a good deal of body moisture to evaporate. The latter occurs when blood flow increases near the surface and the blood vessels in the body's skin expand, permitting the pores to open. The result of this process, called vasodilation, is to present a warm skin area that offers a maximum amount of perspiration. In order to keep the body warm, the process must be reversed, that is vasoconstriction must take place: the blood vessels in the skin and the pores constrict, and evaporation and blood flow are reduced.

A rich blood flow near the surface and the dilation of blood vessels in the skin not only help the evaporation process but also help to carry heat away from the body by convection—a process whereby heat from the warm body is transmitted to colder air moving around the body. Here again, in order to keep the body warm, the process is reversed by reducing the temperature of the skin, which in turn reduces the heat loss by convection.

The body can also lose heat by conduction—a process in which heat is conveyed from a warm object to a *static* colder object. (The major difference between convection and conduction is that convection involves motion whereas conduction involves static elements.) The higher the skin temperature, the greater the rate at which the body's heat will be reduced by conduction through cooler objects in touch with the skin. Conversely, if the skin's temperature is reduced, the rate of heat loss by conduction will also be reduced.

The last process is radiation, or the emission of energy, which is also influenced by skin temperature because transfer by radiation between two objects is dependent on the temperature difference between the objects. When skin temperature is reduced on a cold day, the skin will radiate less heat, and here again, the constriction of blood vessels helps conserve body heat. The amount of blood flowing from the heart to the hands, for example, is not only reduced as the blood flow to the extremities is restricted but the blood is also cooled through the exchange of heat with the blood returning to the heart from the cold extremities. This is something everyone has experienced on a cold day. As the temperature of and the flow of blood to the hand decrease, the skin of the hand becomes colder and the heat loss to the environment is reduced.

This mechanism applies to the feet as well as the hands. The feet constitute approximately 10 percent of the total body surface, but under hot conditions, approximately 13 percent of the body's heat can be lost through the feet. Under cold conditions, when the heat loss might be expected to increase, it may actually be diminished and amount to only 7 percent of the total. Here again, reduced blood flow and reduced blood temperature are the contributing factors. In some cases the temperature of the arterial blood flowing to the hands or feet may be reduced by as much as 15 to 25 degrees before the blood reaches the extremities. The hands and feet may even attain the same temperature as the surrounding environment.

The manner in which the body regulates temperature by controlling its

Copper man (with electric power leads attached to eye sockets) is used to measure the insulating capability of different systems of cold weather clothing.

Photos by U S Army Natick Research and Development Laboratories

evaporative, convective, conductive, and radiative heat losses through skin changes and the circulatory system is internal. But the body's heat loss can also be controlled by changing the amount of body surface area exposed to the environment.

You may not be aware of the way you unconsciously spread your limbs or raise your arms on a hot day in order to cool off. Cats offer excellent examples of this behavior. On a cold day, a cat will curl up not only to minimize its total exposed surface area to the air but also to shield its stomach from the environment. As the temperature rises, the cat will uncurl, stretch out, and in a truly warm environment, may lie on its back or side to deliberately expose its relatively warm stomach area, all in order to cool off. While there are limits to how humans can copy this feline "presented area" approach to keeping warm, it at least reminds us that the various portions of the body differ in their ability to control the body's heat loss. For example, although the blood flow to the extremities can be clearly demonstrated to vary in volume and temperature and thereby to control the body's heat loss, the same is not true of the head. There is no significant automatic control of blood flow in the head. The amount of heat that can be transferred from the head does not change significantly because the blood flow supplied to the brain is fairly rich, relatively constant, and close to the surface. In addition, the skin on the head does not dilate or perspire as much as the skin on the limbs. Finally, the head is relatively free of the subcutaneous fat layer of other portions of the body; hence there is little insulation between blood in the head and the environment.

Although blood flow to the brain is more or less constant, the rate of blood flow as well as the blood pressure can rise in the cold. When this happens, heat is conserved in the head and torso at the expense of the extremities. The cold body has an interesting effect on the bladder. As blood accumulates in the torso, the additional fluid pressure generates the signal to urinate. This is caused by the constriction of blood vessels when the body is cold, although being cold is not usually thought of as the cause of increased excretion of urine.

All of the foregoing suggests that in attempting to protect ourselves from the cold, we might profit from taking a different approach to protecting our limbs and extremities from that used to protect the head. One might be tempted to concentrate on insulating the extremities because they are the areas through which considerable heat loss can occur. If the body's trunk is amply protected, however, heat loss in lightly protected hands and feet may be tolerable. Some individuals feel quite comfortable working with their bare hands even at moderately cold temperatures because they have a greater blood flow to their extremities than other people have. The head, however, is another matter. Even though it represents only about 5 percent of the body area, the head can "dump" from 7 to as much as 50 percent of the body heat, depending on the conditions involved. This strongly suggests that no attempt to protect the body from cold should omit the head. A full head of natural hair is an indisputable asset in a cold environment, but at least for many males, a head covering would seem to be in order. Equally important, the ears represent prime areas through which body heat can escape.

Looking at the clothing we wear to keep warm reveals our limited choices: we can select clothing on the basis of materials or design or some combination of the two. Clothing materials depend on trapped air to provide insulation. The insulation value of trapped air is considerable, since in the absence of turbulence—the replacement of the warmed air by the cooler air—the heat loss is significantly reduced. Clearly, any material that has the capacity to trap air or that can in some other way provide a still-air layer is a candidate for insulation in clothing.

The principle of creating a still-air layer for insulation can be applied to any article of clothing, which seems to suggest that a single insulated garment would be sufficient to maintain the body at a comfortable temperature. Unfortunately, this is not the case. A single garment would not accommodate the tremendous range of human metabolic activity. It might keep the body warm under moderate working conditions but would overheat it during strenuous activity. This problem has led clothing designers to the concept of layered clothing. Individual layers can be opened to permit a greater flow of air between the layers, or the layers can be removed, as needed, to control body temperature.

As people become overheated in a cold environment, they usually begin to open, loosen, or remove their torso clothing while keeping their headgear on. Given the body's ability to remove heat through the head, a more logical heat-regulation mechanism would be to first remove the hat. A multilayered hat system might also provide enhanced control over the body's heat-regulation mechanism in a cold environment.

In attempting to create the best balance between materials and design, we confront the premise that to be useful, clothing materials must be compressible, flexible, and bendable. And they must be able to "breathe" in order to relieve some of the body's moisture. At the knees, elbows, and in the shoulder area, however, the insulation material will be under compression, reducing the volume of trapped air. When the clothing is fully compressed, much of the still air will be forced out and the thermal conductivity of the compressed insulation material will be the factor governing heat loss, along with such radiation as can occur through the material. Body movement is another factor that must be considered in clothing design. The motion of the body and its garments can set up a "pumping" action that introduces some of the ambient air in between the layers of insulation. In many tropical countries, men wear their shirts outside their trouser tops instead of tucked in, as a way of increasing the convective airflow over their torsos by means of the pumping action.

Many new clothing materials that may keep us warmer in the future have emerged in the marketplace. Advances have also been made in the scientific tools to help the engineers, physiologists, and designers working on clothing. Flat-plate calorimeters, which measure the resistance to heat transfer, are available to determine the insulation value of materials both in compressed and uncompressed states. When moisture is added to the plate calorimeter a more realistic simulation of the body is achieved, at least insofar as temperature and moisture are concerned. Researchers, recognizing that the distribution of clothing on the body and the convective currents set up by the body's own heat will influence the heat and moisture absorbed by the clothing, also utilize conductive replicas of the body, usually made of copper. Precise amounts of heat can be sent through these copper bodies, and by measuring the amount of energy required to maintain them at a given tem-

Prime Down—Nature's Finest Insulator!

Pampers you with warmth Keeps fuel costs down

Wrap yourself in the weightless, cozy warmth of soft prime down . . . and turn the thermostat down (as low as 55° F). It's the comfortable way to beat the high cost of energy. And how marvelous that you can treat yourself to the luxury of Mountainside Concepts' prime down coordinated comforters, robes and slippers at prices you can afford!

We're available for toll-free credit card purchases 24 hours a day, 7 days a week **CALL (1) 800-835-2246.** extension 223 In Kansas call **(1) 800-362-2421,** extension 223. For further general information call **201-465-0200.**

PRIME DOWN COMFORTERS . . . plumply filled from corner to corner with soft, fluffy prime down. Luxuriously warm and so light in weight, you'll sleep lots more comfortably without the oppressive weight of layers of blankets. Made to our meticulous tailoring standards—with smooth, tightly woven 100% cotton cambric covers, channel stitched with hidden innerstitching to prevent down leakage and excessive shifting (Sewn-through stitching is never used). They'll stay plump, soft and warm for years of comfortable sleeping. Machine washable, too. Available in 3 sizes and 3 colors: light blue, camel and navy.

Twin Size 66" x 85" **$100.00***
Full/Queen Size 86" x 85" **$150.00***
King Size 98" x 85" **$185.00***

WOMEN'S PRIME DOWN ROBES . . . wrap you in a cloud of soft, cozy warmth. Perfect gift for the gal who likes to snuggle up with a good book on a cold, blustery night! Robes are contour-cut and tailored of down-proof poly/cotton/nylon, generously filled with fluffy prime down. Machine washable. 3 beautiful colors: royal blue, burgundy and chocolate. 3 sizes: Small (8-10), Medium (12-14) and Large (16-18).

All Sizes **$75.00***

WOMEN'S PRIME DOWN SLIPPERS . . . what luxury to slip your feet into the wonderful warmth of cushiony slippers plumply filled with soft prime down. Marvelous to come home to on a cold, snowy night! Fabric is a down-proof blend of poly/cotton/nylon. Machine washable. A perfect complement to our prime down robe . . . in royal blue, burgundy or chocolate. Sizes: Small (5-6½") Medium (7-8½") and Large (9-10½").

All Sizes **$15.00***

***All prices include postage and handling.**

GUARANTEE

We're so sure you'll cherish the prime down products from Mountainside Concepts that we make you this unconditional guarantee: after 30 days, if for any reason you aren't fully satisfied with any of our products, return them for a full refund (including postage). Additionally, we will replace any product we sell if any defects in workmanship or materials appear within five years. We challenge anyone to equal this guarantee

PLEASE NOTE: Mountainside Concepts is a division of MOUNTAINSIDE MARKETING ASSOCIATES INC. Products are made to our demanding standards and are available by mail only.

Thermographs recorded changes in heat distribution as a pair of chilled human hands, above, regained nearly normal warmth, right. Color changes occurred at intervals of about four degrees Fahrenheit, and darker colors indicate lower temperatures.

perature in a room where the ambient air temperature is also precisely controlled, scientists can measure the insulation capability of the clothing put on the "copper man."

Improvements in infrared scanning cameras also make it possible to take photographs of the "heat leaks" in various items of clothing. These cameras create ten-color images, with each color representing a specific temperature range. Such photographs may reveal significant differences in the protection offered by two seemingly similar items of clothing. With a computer coupled to such a camera, a quantitative assessment can be made of the total heat leak shown in the various areas (at various temperatures) in the photographs.

Yet another tool that is becoming more and more useful in the evaluation of clothing materials is the scanning electron microscope, which examines the textures of fiber surfaces in precise detail. That, in turn, provides clues to the ways in which two apparently similar materials may vary considerably in their ability to trap air and thus in their insulation properties.

Given two insulation materials having fibers with the same surface features, the one with the finer fibers provides more surface area and hence a greater proportion of still air. With two materials of the same fiber diameter, the one possessing small surface discontinuities on the fiber will present the greater surface area and thus a higher proportion of still air.

One way to examine the effect of surface area is to look at some comparative dimensions. Fiber length (or, in the case of feathers, vane length) per gram is the pertinent measure. Synthetic fibers in modern insulation materials may contain as much as a mile of fiber length per gram. By contrast, feathers might yield eight miles of fiber length per gram and high-quality down thirty-two miles per gram.

A comparison of feathers with down demonstrates the insulation limitations imposed by the feather's quill. A quill can represent 25 percent of the feather's total weight and provide very little surface area. In eiderdown, on the other hand, the comparable portion of the structure that contributes little to its insulation is only 8 percent of the total weight. Feathers and down also differ markedly in structure. Feathers are two-dimensional, with vanes emerging on opposite sides of each shaft. Down, on the other hand, is three dimensional. Small wonder, then, that feathers are more apt to pack and compress, while down can be fluffed and tends to remain fluffed up.

Among the natural fibers used in clothing, particularly for warmth, wool offers many desirable characteristics. Fine wools, with a fiber width of 17 microns (about 0.0007 inch), present a large surface area, and wool fibers possess a wavy structure, or crimp, that serves several useful purposes. Crimped fibers interlock more readily, so that they hold together when twisted into yarns. More important, the crimp yields a strong, not easily matted yarn without much twist—just what is needed to produce a porous, low-density structure for insulation.

In designing clothes for warmth, the synthetic-fiber industry cannot be overlooked. Considerable progress has been made in developing materials that begin to duplicate some of the desirable characteristics of natural fibers. Polyester filaments—fibers made of a long-chain synthetic polymer—can be produced with fine diameters, and can also be crimped to provide lofty yarns. Yet another refinement is hollow polyester fibers, which offer significantly greater surface area per unit of length or weight than solid fibers because they are hollow. For example, DuPont's Hollofil (also marketed under the name Hollobond) is an insulation material consisting of hollow polyester fibers that are staple, or short cut (as opposed to the continuous-filament synthetic materials), and have an average length of 2.5 inches and a diameter on the order of 23 microns (about 0.0009 inch). With such short cut fibers, the batting must be quilted to keep the fibers from migrating.

Although quilting has the disadvantage of producing areas of reduced insulation because of compression, it has the advantage of assuring that the fibers will be kept in proper distribution during laundering. Maintaining a uniform distribution of insulation material within a garment is important. Even the best and most expensive insulation materials, such as high-quality down, become relatively useless if they become matted (as

down does, when wet) or if they migrate, leaving areas of reduced insulation. On this score, synthetic fiber insulation materials have a distinct advantage over down in that they take up relatively small amounts of water.

Polarguard, patented by the Celanese Corporation, is another example of a relatively new insulation material. It consists of crimped continuous filaments of polyester, with fiber diameters also on the order of 23 microns. An acrylic resin binder is applied to the surface of the polyester for fiber stabilization and, in conjunction with the crimped fiber form, yields an insulation material that does not easily migrate and shift, thereby eliminating the need for quilting. The fiber crimp also allows the material to simulate the lofty characteristics of such natural materials as wool.

One of the newest insulation materials is the 3M Company's Thinsulate Type C system, which consists of 60 percent polyolefin fibers and 40 percent polyester fibers—two different types of synthetic compounds. While the polyester fibers are on the order of 38 microns (0.0015 inch) in diameter, the polyolefin fibers are of far smaller diameter, with most of them ranging from 1 to 3 microns (0.00004 inch to 0.0001 inch). The term *microfiber* is probably more correct for describing materials of such fine filaments.

The microfibers in Thinsulate C contribute a significantly greater surface area than thicker fibers, thereby trapping more air; as a result, the material has greater insulation value per unit of thickness. On a weight basis, however, both of the previously mentioned all-polyester synthetic materials provide equal insulation per unit weight. (And in terms of weight and thickness, down surpasses all three of the synthetics.) Undoubtedly, future developments in synthetic fibers will yield insulation materials with reduced weight and bulk. The latter is a critical part of the clothing problem because when a person is moving around in cold weather, a small amount of bulk can result in an excessive expenditure of energy.

Much of the work in evaluating synthetic insulation materials under demanding environmental conditions has been done at the U.S. Army's laboratories at Natick, Massachusetts. Unlike the civilian sector of society, which can buy an array of products priced to fit the budgets of a variety of customers, the Army must pay primary attention to

UNSPOILED.

There are few places left on earth that are unspoiled. Sri Lanka is one of them. Once known as Ceylon, Sri Lanka has Asia's best game preserves. 200 species of animals, 425 kinds of birds and hundreds of square miles of leopard, elephant and sambur.

The wild flowers of Sri Lanka include a dazzling display of orchids. And where else could you find 600,000 acres of tea gardens on misty mountains?

There are 75 ways you can tour Sri Lanka. Ranging from 3 to 21 days. Accommodations begin at $5. Deluxe sells for $45. Never has your dollar worked harder. From shopping to sightseeing.

In our ancient cities, you can enjoy frenetic festivals that reflect the unspoiled nature of a culture which dates back 3,000 years.

Whether your visit is pleasure, business or a convention, our unspoiled country will spoil you. Just one hour from India, three hours from Katmandu, Bangkok and Singapore. Write for a color flyer and tour digest that includes special airfare.

CODE OF THE QUIPU

A Study in Media, Mathematics, and Culture

At the height of their civilization the Incas had no system of writing, but instead used quipus — colored cords, knotted in a special manner — to record and transmit information. Based on a study of quipus found in Inca graves during 19th- and 20th-century excavations, *Code of the Quipu* presents a fascinating anthropological and mathematical study of the problem of interpreting artifacts from a distant culture.

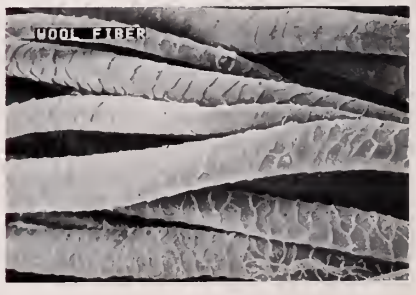
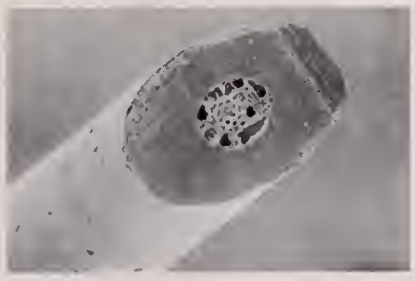
cost. As the price of down has escalated, the newly developed synthetic materials have become of greater interest to the military. The Army also routinely expects to conduct field operations at temperatures of −40°F, and in the evaluation of its extreme cold weather sleeping bag, stringent test requirements were set: the bag would not be considered acceptable unless a soldier could get at least six hours of uninterrupted sleep at −40°. The sleeping bag that passed this test and is now in the Army's inventory contains polyester as well as some strategically placed down. (It should also be noted that synthetic insulation materials are nonallergenic, they do not usually develop any noticeable odors, and they are resistant to attack by microorganisms. These features, along with the materials low moisture pickup, are of considerable importance to the Army.)

For a number of years, efforts have been made to supplement the insulation of clothing by creating a reflecting layer that would reduce the body's heat loss through radiation. Even under ordinary indoor conditions, about 50 percent of the total heat loss through the skin takes place through radiation. Ideally, to keep us warm, our clothing should incorporate a reflective layer that would return to the body some of the heat lost through radiation. This concept has been explored for a number of years but without success. Part of the reason is that the infrared characteristics required in a reflective layer can usually be achieved only by means of a continuous bright metallic surface. If that surface becomes broken or coated with a foreign substance (such as dirt or a body excretion), its reflectance characteristics would be significantly reduced. In addition, for a reflective layer to work, a finite distance must be maintained between the emitting and reflecting surfaces. This would require a spacer material that would keep the two surfaces apart and not allow any significant heat conduction. To date, no such material has been found.



Perhaps the most adventuresome new concept in cold weather clothing derives from recent information concerning polar bears and harp seals. A few years ago, an attempt to photograph these animals from the air to obtain a population count proved difficult because white bears and white harp seals do not show up against white ice. The photographers then experimented with infrared film on the reasonable assumption that creatures containing warm blood might emit radiation in the infrared range that could be recorded on infrared film. To the photographers' surprise, the infrared exposures were equally disappointing and did not differentiate significantly between the harp seals and polar bears and the ice on which they



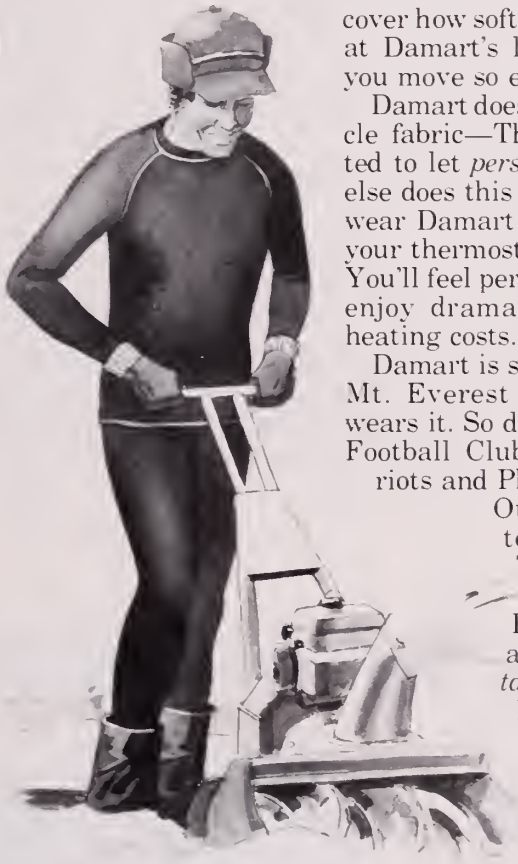
Scanning electron micrographs reveal the structure of natural and synthetic insulation materials. The insulating properties of the materials depend on their ability to trap still air.

The structure of a polar bear hair, magnified hundreds of times in this scanning electron micrograph, may hold the key to new ways of designing protective clothing.

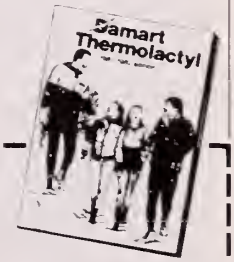
were lying. But when the photographers used ultraviolet film, the results were startlingly successful. The bears and harp seals showed up as black objects on the white ice, indicating that the animals were thoroughly absorbent in the ultraviolet range. This phenomenon was intriguing enough to prompt a study of polar bear skin and hair.

Analysis showed that the tapered bear hair is not really white but is a pigmentless structure with a core of such low density that it is nearly hollow. In simple terms, the polar bear's white appearance is caused in large part by internal reflections in the polar bear hairs. This is analogous to the way in which the whitish appearance associated with ice derives from light reflection off of many internal surfaces. With photographic evidence showing that the polar bear was absorbing energy in the ultraviolet range, there was another question to be answered: Was the low-density core of the bear's hair acting as a "light pipe," permitting the absorbed ultraviolet energy (perhaps now transformed into another form of energy) to be transmitted into the bear's hide through internal reflections? A mathematical model of polar bear hair showed that this was entirely possible. That may mean that in addition to providing useful insulation, polar bear hair may be even more valuable in energy gathering, functioning as a special kind of solar cell. Perhaps tomorrow's cold weather clothing will be made of materials that go far beyond today's "trapped air" insulation techniques and emulate instead the hair of the polar bear. It's something to think about. □

COLD ALL WINTER LONG?



Wherever the winters are cold, with temperatures in the "teens" and "wind-chill factors" even lower, people are talking about Damart Underwear.



And no wonder! Damart is the unique underwear that keeps you amazingly *warm, dry and comfortable* no matter how cold it gets, no matter how hard the wind blows. No matter how long you stay out! You'll have to run your fingers over Damart Thermolactyl to discover how soft it is! You'll be thrilled at Damart's light weight that lets you move so easily.

Damart does this with a new miracle fabric—Thermolactyl. It's knitted to let *perspiration out!* Nothing else does this like Damart! You can wear Damart indoors too, and turn your thermostat down into the 60's. You'll feel perfectly comfortable and enjoy dramatic savings in home heating costs.

Damart is so comfortable that the Mt. Everest climbing expedition wears it. So does the Chicago Bears Football Club, New England Patriots and Philadelphia Eagles.

Our free color catalog tells the full Damart Thermolactyl story and displays the whole Damart line for men and women, *including tall sizes.* Send for your FREE copy now!

Come, Gather Round the Chimney

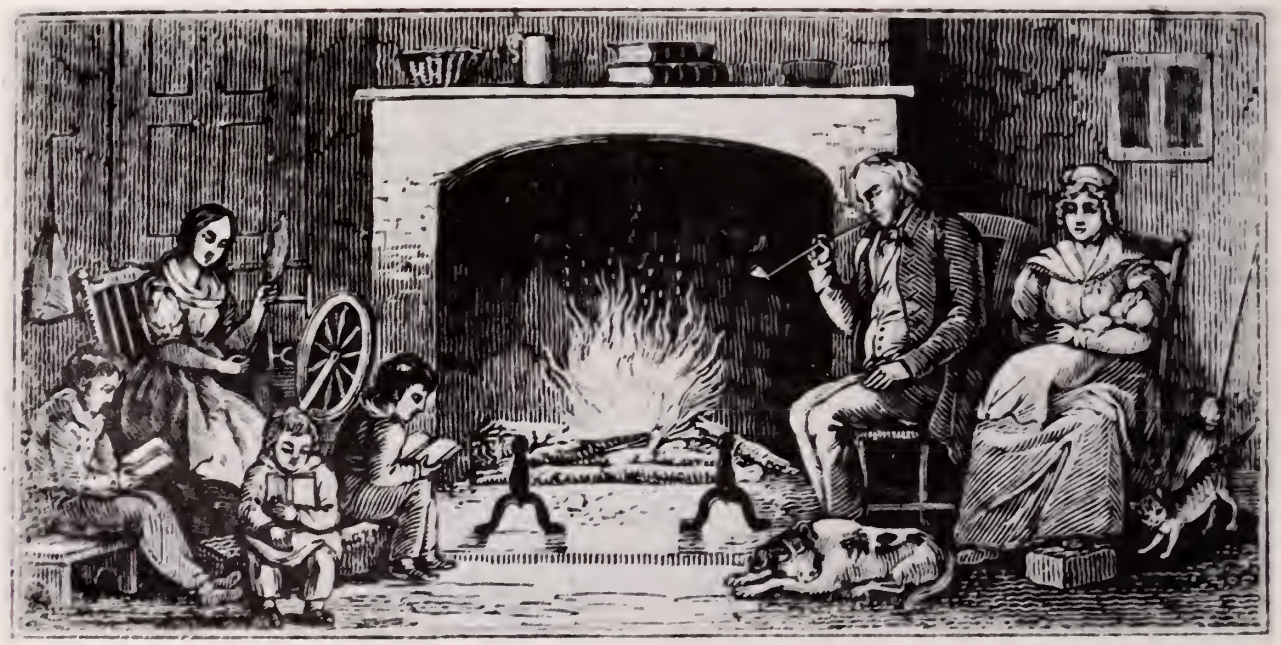
Staying close to the hearth provided only relative comfort during New England winters

by Jane C. Nylander

In January of 1810, the Reverend William Bentley of Salem, Massachusetts, commented in his diary: "The severest cold I ever knew. . . . Several Old Persons perished within doors. In my own Chamber on Saturday, with a brisk fire, I found the Therm. on the southern side of the Chamber at the greatest distance from the fire at 3 P.M. 16 Far[enheit]. below freezing."

Modern Americans who complain about presidentially mandated daytime temperatures of 68° might learn something about stamina and endurance from a close examination of the life styles of Bentley's early New England contemporaries. Those who have mastered the technology of solar panels or the servicing of an airtight stove, however, can take comfort in the advantages of modern methods of keeping warm that use the same fuels that were available to the good Doctor. These people are involved in an ongoing process of experimentation with improved heating methods and more efficient use of materials that was beginning even in early-nineteenth-century New England.

Coping with winter's chill in the days before there was any kind of central heating required considerable labor and forethought. No one could hope for even a degree of comfort without careful preparation and significant expenditure of money, personal energy, or both. Yet even for those who could afford all the fuel they wanted, it was almost impossible to keep a house warm by relying exclusively on open fireplaces. Anne Jean Lyman wrote of her girlhood home in Milton, Massachusetts:



> The winters were long and cold; the appliances for heat not what they are now, the large open chimneys and wood fires being cheerful to the eye, but with their ample draughts not warming to the body. We wore our great coats in the house half the time, Sally and I, and even then could not have been warm without the active employments that kept us constantly busy.

One family recorded "the coldest day we have had" on which the thermometer outside stood at twenty below zero. Upon arising, the family found that the thermometer in the bed chamber stood at three degrees, and with a good fire throughout the morning they were only able to raise it to eight degrees by noon. Apparently, other rooms in the house were somewhat warmer, and some members of the family descended to the parlor to dress beside the fire there. One suspects that the chamber thermometer was not hung near the fireplace, but the actual spot is not recorded.

The winters of New England are often reputed to have once been colder, longer, and snowier than those of modern times. Harriet Beecher Stowe wrote in her novel *Old Town Folks:*

> One of my most vivid childish remembrances is the length of our winters, the depth of our snows, the raging fury of the storms that used to rage over the farmhouse, shrieking and piping round each

N Y Public Library/Coxe-Goldberg Photography

Chairs were pulled as close to the open fire as possible.

angle and corner, and thundering down the chimney in a way that used to threaten to topple all down before it.

In the works of Emerson and Longfellow such storms are depicted in vivid imagery intended to set the scene for an intimate moment forced on people by the power of nature. Despite the dramatic images of depth of snow and intense cold conveyed by poets, novelists, and diarists, careful study of actual winter conditions by historians and meteorologists indicates that these accounts describe extremes. Just as the great eastern blizzard of 1978 will live in the memory of all who experienced it, unusually cold or snowy seasons and severe storms made a vivid impression on people's minds, providing the foundation for these dramatic descriptions.

It is true that there were drifts of snow as high as fourteen feet in late winter of 1717, when Cotton Mather described "as mighty a snow, as perhaps has been known in the memory of man." The year 1816 is frequently referred to as the "year without a summer" for there were frosts every few weeks from May to September. Even Dr. Bentley's January 1810 morning was widely known as "cold Friday"; for generations New Englanders recounted the effects of the spectacular overnight temperature drop of more than fifty degrees and its accompanying severe wind chill. We should remember, though, that diarists and tellers of tales alike have a tendency to record the unusual rather than the commonplace, so it is not surprising that one finds an occasional notation of water in a washbasin or ink in an inkstand freezing in March or October. Such things certainly happened often during the coldest months, but because they were expected at that time of year, they did not provoke comment and were dealt with on a day-to-day basis.

By the end of the eighteenth century, many people realized that large, open fireplaces were not efficient sources of heat. Fireplaces in seventeenth-century New England houses were aptly described as cavernous. We can easily believe the descriptions of people moving a small group of chairs right into one corner of the hearth, since most of the heat of any fire would have gone directly upward through the wide, damperless flues. Even a huge fire built with "a very forest of logs" was not enough to warm much of a room, although some warmth was gained near the fire itself. Eventually, the fireplace would begin to

If you'd like to know some other unusual things about Lynchburg, drop us a line

WHEN GOOD FRIENDS GET TOGETHER in downtown Lynchburg, you'll never see a glass of Jack Daniel's.

The county where we make our whiskey is dry. (It voted that way in 1909.) So when folks have a friendly chat, it's usually over ice cream or soda. Of course, we hope the law isn't as binding in your hometown. And that, at your next friendly get-together, a glass of Jack Daniel's will be somewhere in the picture.

radiate heat directly into the room, driving the cold back into the corners. The process juxtaposed radical extremes of heat and cold, a confrontation made vivid by John Greenleaf Whittier in his poem "Snowbound": ". . . the red logs before us beat/The frost-line back with tropic heat."

Masons and housewrights gradually realized that smaller fireplaces would be more efficient. By the early nineteenth century, most New England fireplaces, with the possible exception of those in kitchens, were much smaller and shallower than those that had been built a hundred years earlier. The newly constructed fireplaces had smaller throats and sharply angled sides designed to reduce the amount of heat lost up the chimney and to increase the amount radiated into the room. The published works of Massachusetts natives Benjamin Franklin and Benjamin Thompson, Count Rumford, explained new methods of building fireplaces that were at once more efficient and less smoky. In many of the earliest houses, the smaller fireplaces were built right inside the old ones. Sometimes this process was repeated more than once with an even smaller fireplace being constructed inside the preceding ones in a continuing attempt to increase heating efficiency. Kitchen fireplaces remained larger as long as they were used for cooking because space was needed to accommodate not only a main fire with its large pots and kettles suspended from a crane or a lugpole and trammel (a device for hanging a pothook) but also several small piles of coals and the gridirons, trivets, toasters, and spiders being used to cook over them. A huge roaring fire was not advantageous for cooking since there was no way to control its heat, but maintaining a useful pile of glowing coals for cooking often resulted in a chilly room. Thus Harriet Beecher Stowe could describe how "Aunt Lois, standing with her back so near the blaze as to be uncomfortably warm, yet found her dish-towel freezing in her hand, while she wiped the teacup drawn from the almost boiling water."

To conserve heat provided by a kitchen fire many New Englanders hung blankets from a wooden "blanket crane" or from a series of iron ceiling hooks in front of the fireplace. High-backed wooden settees drawn up to the hearth served the same purpose. By enclosing a small space, it was possible to maintain a more even level of warmth. The daughter of the Knight family of Hancock, New Hampshire, recalled that her mother built a sort of tent near the fireplace on the coldest days, suspending blankets around the children to protect them from the bitter drafts of air that blew in around the windows and through the cracks in the walls of their house.

Many early New England houses were constructed with central chimneys, which even when only one fire was actually lighted always kept some warmth radiating through the building. Against such a chimney, grapes ripened, eggs hatched, motherless infant lambs and calves warmed, and geraniums kept from freezing. In a chimney cupboard, wines and fruitcakes were left to ripen.

Herman Melville saw a purpose to the chimney's warmth in developing "cordials, to a choice mysterious flavor, made so by the constant nurturing of the chimney's gentle heat, distilled through that warm mass of masonry. Better for wines is it than a voyage to the Indies; my chimney itself a tropic." This seems somewhat romanticized when we consider ink bottles frozen on the mantlepiece and washbasins frozen and cracked upon the hearth! But Melville saw the central chimney in his house as a source of family unity, and in "I and My Chimney," he praised the fireplaces that

> all congregate in the middle—in one grand central chimney, upon all four sides of which are hearths—so that when, in the various chambers, my family and guests are warming themselves of a winter's night, just before retiring. Then, though at the time they may not be thinking so, all their faces mutually point to one center; and when they go to sleep in their beds, they all sleep round one warm chimney, like so many Iroquois Indians.

Houses, such as Melville's, with a central chimney, had no hallways. The rooms opened on to one another, depriving the occupants of privacy but encouraging in them a sense of interdependence—a feeling of community that Melville saw as another virtue of central chimneys.

Although most center-chimney houses were built with three or more fireplaces per floor, fires were not kept burning in many rooms at one time, especially when there were rooms that were not occupied. The danger from flying sparks and coals was enormous, and the amount of wood or other fuel required to maintain constant fires was

tremendous. Harriet Beecher Stowe describes a rural house as follows:

> The one great central kitchen fire was the only means of warming known in the house, and duly at nine o'clock every night, that was raked up and all the family took their way to bed chambers that never knew a fire, where the very sheets and blankets seemed so full of stinging cold air that they made one's fingers tingle: and where, after getting into bed there was a prolonged shiver, until one's own internal heat-giving economy had warmed through the whole icy mass. Delicate people had these horrors ameliorated by the means of a brass warming-pan—an article of high respect in those days.

In many homes, heated bricks or stones were used as foot warmers in beds, but the real luxury was a bed warmed by a long-handled metal warming pan filled with hot coals and then rubbed smartly between the cold sheets, thereby imparting a freshly ironed surface to the linen and a bit of temporary warmth to the entire bed. Some staunch New Englanders regarded the use of warming pans as a luxury to be reserved for the sick or the elderly, but for those who yielded, the warmth was real.

Faced with the difficulty and danger of heating a large number of rooms during the coldest months, many people reduced their actual living space within their homes, closing off unneeded rooms and rearranging furnishings. Jonathan Sayward of York, Maine, wrote in his diary of the seasonal ritual of taking down and setting up his high post bed in different chambers. During the extended absence of her husband during one Vermont winter, Mrs. Royall Tyler moved her bed into the north parlor, her two younger children slept in the bed with her, and the older ones slept in a trundle bed in the same room. Anne Lyman wrote to a friend, "Our house is warm enough, that part which we use." Household furnishings of this era were usually light and, with the exception of high post beds, they could be moved fairly easily within a household in order to take advantage of a steady source of heat, adequate light, or a change in circumstances. Arrangements of room furnishings were not maintained for months or years at a time as they are today. Drop-leaf or folding tables, lightweight side chairs, small stands, and sewing tables could easily be assembled—for an activity or a meal—near a window with bright sunlight streaming through it or near a warm fireplace. Upholstered furniture was rare before the end of the eighteenth century, the most common form being side chairs. Comfortable easy chairs were expensive, yet those who could afford them used them functionally, drawn near the fireplace in a bed chamber where their broad wings offered added protection from drafts of cold air.

During this period, spaces within houses were normally defined by their location or function. Historians find references to southeast and northwest parlors or chambers, kitchens and keeping rooms, sitting rooms and dining rooms. There were best rooms and family par-

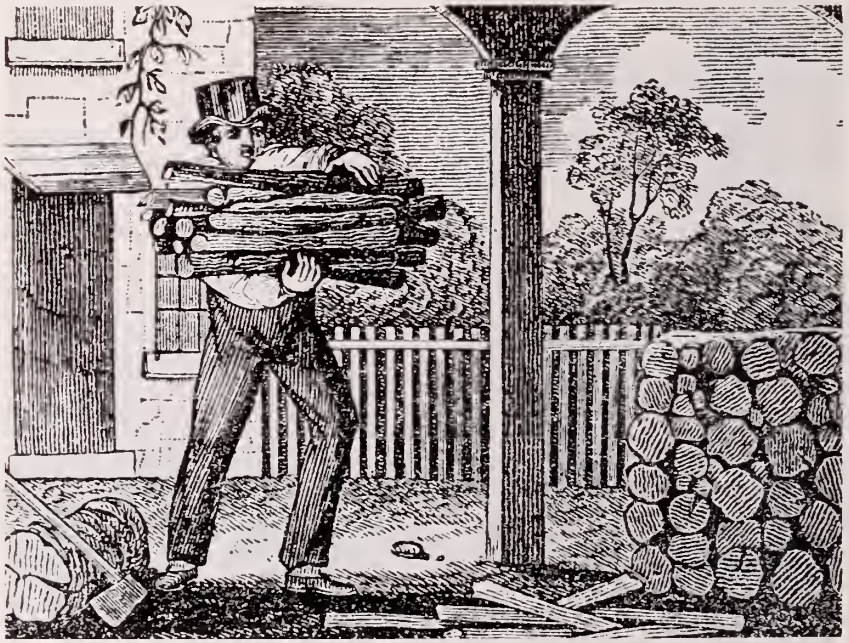
lors, but rooms were not designated by the names or sexes of the occupants. There seems to have been no concept of personally defined space in the twentieth-century sense. Melville's concept of interdependence is reinforced by more than the image of a house without hallways. Sleeping arrangements were apt to be far more informal than they are in our post-Victorian period. Studies of the inventories of early houses show that beds were set up almost anyplace. In the seventeenth century, the best bed, normally occupied by the parents of a family, was usually set up in the hall, a multipurpose room that was at once the most used and the most expensively furnished room in the house. In later times, the best bedroom moved to the second floor although, as we have seen, the bedstead itself might be moved when the coldest months arrived.

Children and servants might sleep in rooms that were furnished with an assortment of tools, storage containers, and miscellaneous objects such as saddles, fishing equipment, or old spinning wheels. They might also find themselves sleeping in spaces that were not even finished rooms: for example, attics, second-floor lean-tos, and the spaces at the top of back staircases. Harriet Beecher Stowe described the experience of two boys sleeping in such a space in winter in her novel *Old Town Folks*. Waking in the morning to find that a lighted candle had been placed on a large chest by an early-rising relative, one confessed that "one of my sinful amusements consisted in lying and admiring the forest of glittering frostwork which had been made by our breath freezing upon the threads of the blanket" in a room where "the snow, drifting through the loosely framed window, often lay in long wreaths on the floor."



Frugal housewives were not unaware of the advantages to be gained by freezing food in such spaces. Some early cookbooks recommended quantity cooking in the late fall when ingredients were abundant. One suggested that as many as one hundred pies be baked at Thanksgiving time and then stored in blanket chests in cold bedchambers. Mrs. Stowe described

> a great cold northern chamber, where the sun never shone, and where in winter the snow sifted in at the window cracks, and ice and frost reigned in undisputed sway ... fitted up to be the storehouse of ... surplus treasures. There, frozen solid, and thus well preserved in their icy fetters, they formed a great repository for all the winter months, and the pies baked at Thanksgiving often came out fresh and good with the violets of April.

Unless, that is, there was a January thaw!

Despite its advantages in food preservation, extreme cold in kitchens was an inconvenience as well as a source of personal discomfort. In 1793, Anna Palmer described a problem of provid-

Old Sturbridge Village, photo by Henry E. Peach

A good supply of winter firewood required considerable labor.

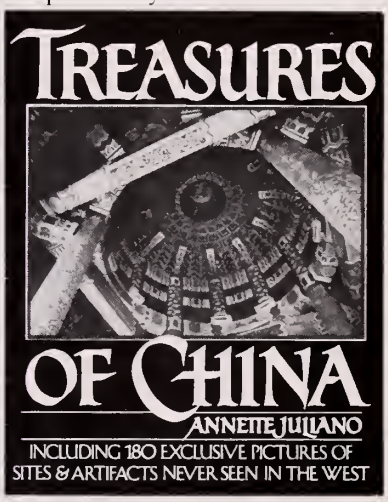
ing hospitality when a guest arrived late one cold winter evening. "It was very inconvenient," she wrote, "the fire in the kitchen had been out for hours and everything was frozen." She was obliged to start another fire, and to thaw cheese, water, and bread before she was able to serve her guest a simple meal of tea, toast, and cheese. Even daily kitchen chores were rendered difficult by severe cold. One housekeeper noted in her diary, "Hard frost is very inconvenient in one's larder. You cannot lay by a little broth or gravy without its becoming as hard as stone, sometimes breaking the vessel that contains it, and not available on short notice."

The cold drafts of which the early diarists and letter writers complained were difficult to prevent, for cracks opened up in even the most well built houses as wood and putty shrank or glass cracked. In areas of new settlement, houses were quickly constructed of green wood, and it was particularly difficult to keep out drafts during the first few heating seasons. A variety of measures were used to seal up cracks or prevent drafts. Banking the house foundation with leaves, straw, and other vegetative debris appears to have been a common practice in rural areas. Noah Blake of Deerfield, Massachusetts, used cornstalks and pumpkin vines for this purpose in December of 1802; many other New England diarists describe the practice without specifying the material used.

By the 1830s there was a growing number of domestic advice books, directed primarily at women and offering suggestions for every aspect of housekeeping. One author, Miss Leslie, published a very practical volume, *The House Book,* with a number of suggestions for coping with cold drafts indoors. Thick strips of wood covered with baize (a green woolen cloth) might be nailed to the outside of doors to serve as a sort of weatherstripping. Leslie also described seeing in "old fashioned houses" of the wealthy, "gilt or morocco leather, pinked or scalloped at the edge, tacked with gilt or brass nails round the crack of a door, and as it was considered ornamental as well as useful, it was left there all summer." She also described much simpler and more economical methods of forestalling drafts, such as "keeping the key always in the lock" and making long narrow bags of carpet or other thick cloth and filling them with hard sand before placing them against the threshold of a closed door.

Although the use of storm windows was not widespread before the late nineteenth century, several authors of domestic advice books in the 1830s, including Miss Leslie, point out such "double sashes" could be used in northern climates to increase efficiency in domestic heating. Others suggest pasting thick paper over cracks in window glass and frames or covering small pieces of wood with wool and placing them against the sides and bottoms of loosely fitting windows. Cracks were more commonly stuffed with wool or cotton batting or small pieces of cloth, but in the spring or during a temporary mild spell the wedges of wood were certainly easier to remove than were the sodden clumps of cloth or batting.

Heating and cooking stoves were known and available in New England in the last half of the eighteenth century, but few were used until the decades after 1820. It is not altogether clear why stoves began to be more widely manufactured and accepted after this date, but we know that from that time they were used in rural areas as well as in cities. Newspaper editors and stove manufacturers and dealers urged the adoption of stoves for their increased efficiency and more reliable heat. Many small foundries started casting stoves and a flood of new designs with technological improvements and decorative variations began to revolutionize domestic heating. Mrs. Royall Tyler may have summed up the feelings of many when she wrote that she felt "disposed to vote for a monument to the memory of the first inventor of family stoves; truly the people of this age know little of the horrors of winter."



For all the hardships and inconveniences of a New England winter, it was a time when the rigor and tempo of agricultural work slackened somewhat and people of all ages could look forward to the pleasures of sociability, reading, and indoor recreation. Ample snow meant good sleighing, coasting, and skating. Many agreed with the author who, looking beyond the cold, saw that winter was a season "capable of being so passed, as to give a great deal of instruction, health and pleasure. It is a good season for social visiting and particularly favorable for reading, study and needlework. Then, too, it has our venerable Thanksgiving holyday." Winter has never been easy, but it is much more than shivering and hard work. □

Masterworks no Westerner has seen before.

This book is a rare event. More than 300 specially commissioned full-color photographs capture the splendor of China's finest palaces, temples, gardens and museums. Provided exclusively for this book by the government of the People's Republic of China, well over half of them are shown here for the first and *only* time. In no other book is the abundance, the glory, the *scope* of Chinese art presented with such variety from so many dynasties and places.

Supported by an illuminating text that explains the history as well as the significance of each artifact and site, TREASURES OF CHINA is a unique introduction to the wonders of the vast and largely unknown culture that is perhaps the greatest in the world.

House Warming

How an old farmhouse was insulated and heated to stay warm in cold weather

by Edwin Kessler

Eight years ago, my wife and I decided to leave the small city of Norman, Oklahoma, where I work, and move to the country, where we could be close to the land. In September 1973 we bought a farm in Purcell, about sixteen miles southwest of Norman. Situated on 215 acres, the original house, built in 1904, was uninsulated, had no central heating system, and consisted of three rooms—a bedroom, a kitchen, and a dining-living room. Successive owners had added kitchen plumbing, a bathroom, a laundry area adjacent to the kitchen, a small room that served as a bedroom, and a porch. When we moved in in 1974, the dining room, kitchen, and bathroom had propane stoves.

Siding of composition board and asphalt tile had been added to the outside over the years and the interior walls had been finished with Sheetrock and wallpaper. Nevertheless, there were many openings through which winter winds made their presence known. To maintain a comfortable temperature on cold, windy days, it was necessary to turn all three stoves up high.

During the early summer of 1974, Herbert Prater, a local Baptist preacher and carpenter, examined the house at my request and pronounced it basically sound. I then asked him to renovate the interior and insulate the house. The original ceilings were more than eight and a half feet high, one-half to one foot higher than is standard in modern construction. Their height allowed us to make alterations with unusual insulation qualities.

Prater placed studs around the room perimeters and laid ceiling joists, as is customary with new construction, but below the old ceiling. Fiberglass insulation was then installed in the walls and ceilings. The result was double walls and double ceilings with insulation exceeding that common in new construction. During the remodeling, most of the original window dimensions, 2½′ by 4′, were retained, but the traditional window sashes were replaced with storm windows, and storm doors were installed at the front and rear entrances.

We moved in when the remodeling was finished and found during the following winter of 1974–75 that sufficient heat was provided by just one propane stove—the one in the dining room. Accordingly, we removed the other two stoves, thereby gaining additional floor space, saving some money, and enhancing our safety and convenience.

In 1975, we contracted with Prater to make further changes. Six hundred and fifty additional square feet were added to the house, to include a second bathroom, a study, and a living room, all insulated, of course, and equipped with storm windows. A beautiful brick corner fireplace was built in the new living room with a fan-driven Heatilator to circulate room air around the firebox and back into the room again.

Storm windows bear directly on energy efficiency, costs, and comfort.

Edwin Kessler

A wood-burning cast-iron stove, which replaced the brick fireplace in the living room, uses less wood and is more heat efficient.

More than half the total heat loss in a house in winter can come from closed but ill-fitting windows. Tight construction with a double window sash can cut this heat loss by 50 percent or more and thus reduce overall heat loss by 25 percent or more, while decreasing the temperature differences between windows, floors, and ceilings. In addition, storm windows help maintain significantly higher humidity inside the house in winter. This is desirable because extremely dry interiors can cause respiratory discomfort and aggravate such illnesses as head colds and influenza.

The inner surface of a single window acquires a temperature only a little higher than that of the outside air and transmits that temperature to the interior air. Interior air cooled by contact with the window then deposits most of its moisture on the inside of the window in the form of water drops or even ice. When the cooled room air circulates away from the window area, it is warmed by mixing with other room air, but there is rarely a moisture source elsewhere in the room comparable to the "sink" at the window. This condition is largely alleviated by installing a double window because the inner glass surface presents a higher temperature than the outer glass, and condensation on the inner window is correspondingly reduced.

We installed electric resistance heaters (akin to the burners of an electric stove but containing fans) in the walls, for use as an emergency heating backup. In the new, approximately 420-square-foot living room, there is now a 4-kilowatt electric heater, but this alone is not large enough to maintain a comfortable temperature on cold and windy days, and it costs twenty to twenty-five cents per hour to operate. The fireplace could heat nearly the whole house above 72°F under practically any conditions of outside cold; but wood-burning rates on cold days were about ten pounds of wood per hour. While there is plenty of wood on our farm, it has to be cut, hauled, and stacked. Also, fires have to be fed and ashes have to be removed. In view of the time and effort involved with so much wood, we usually hung a blanket in the hallway joining the old and new parts of the house to prevent circulation of air, and during the winter we used the new living room and fireplace only when we had guests.

A fireplace radiates heat and a Heatilator makes an additional contribution

RAIN-SHEDDING RAGG WOOL

Ragg Wool Balaclava is styled like headgear worn by the British in the Crimean War. Today, it's the choice of backpackers, sailors and cross-country skiers. Undyed Ragg yarn is spun of 85% lanolin-rich wool for warmth and water repellency plus 15% nylon for strength. Balaclava folds up like a watch cap or turns down to cover your ears, chin and neck. Eye-shading visor. One size fits all. **Color:** Salt & Pepper. **Ragg Wool Balaclava $7.50** ppd.

Ragg Wool Slouch Hat takes its shape from the "bucket crown" Irish field hat. It hugs your head and shields your eyes from drizzle or sun. Knit of 85% wool with natural lanolin for warmth and water repellency, 15% long-life nylon. Folds for tucking in pocket or glove box, unpacks wrinkle-free. One size fits all. **Color:** Salt & Pepper. **Ragg Wool Slouch Hat $13.95** ppd.

Telescopes from Celestron®

Will Take You To Places You've Never Been To Before
• Versatile • World's Largest Selection • Supremely Affordable

With a Celestron, the modern standard of high quality, affordable telescope performance, you can explore the craters of the Moon, the rings of Saturn, twirling galaxies and glowing nebulae. You can easily use a Celestron to photograph and view terrestrial subjects.

All Celestron telescopes have laser-tested, diffraction limited optical systems with hand-figured optics made in the U.S.A.

Celestrons® are available from 1.2- to 14-inches in diameter including the world's most popular modern telescope, the versatile Celestron 8. And, remember, most 35mm cameras easily attach to the Celestron for photography.

Free 8-page brochure or send $3.00 for 52-page full-color catalog on how to select and use a Celestron telescope/telephoto lens.

ARCHEOLOGY TOUR TO MEXICO **January 11-29, 1982**
ANCIENT MAYA ARCHEOLOGY **February 1-18, 1982**

Discover the ancient civilizations and archeology of pre-Columbian Mexico and the Maya world with the American Museum's C. Bruce Hunter. Sites on the Mexican tour include Mexico City, Cuicuilco, El Tajin, Jalápa, Cholula, Teotihuacan, Tula, Oaxaca, Mitla, Monte Alban, Cuernavaca, Xochicalco and Taxco. The Maya tour includes visits to Merida, Dzibilchaltun, Chichen Itza, Tulum, La Venta, Palenque, Edzna, Uxmal, Sayil, Xlapak and Labna. Tours include colonial towns, museums and the finest accommodations, and are limited to 18 participants. C. Bruce Hunter is Lecturer in Archeology at the American Museum, and author of A Guide to Ancient Mexican Ruins and a Guide to Ancient Maya Ruins. For further information write to DISCOVERY TOURS, American Museum of Natural History, Central Park West at 79 St., NY NY 10024, or call (212) 873-1440.

to the warming of room air. (Our Heatilator was a metal firebox in lieu of a traditional brick lining. Openings faced the room on each side at floor level and above the fireplace. Fans installed behind the lower openings sucked cold air in from the floor and blew warmed air back into the room from the top openings.) The contributions to heat gain from a fireplace, however, are more or less offset by the loss of room air that is drawn up the flue. The warmed air is replaced by cold outside air that enters through cracks anywhere in the house. This effect cannot be prevented—a house that is airtight except for its flue cannot support a functional fireplace and will fill with smoke. Thus some fireplaces actually cause the average house temperature to fall when they are in operation. To alleviate this, at least in part, it is good practice to provide a source of outside air at a point near the fireplace.

Fireplaces are most efficient when the damper is as nearly closed as it can be without creating a pall of smoke, but even then they are not remarkably efficient. Some improvement can be achieved by covering the front of the fireplace. Glass doors with control vents are available for this purpose.

In an effort to improve the efficiency of our fireplace, I hung steel plates over the front from pegs welded to the top. Similar to glass doors but much less costly, these noticeably reduced the draft and provided a measure of safety at night when the fire was left burning but unattended. Nevertheless, the burning rate required to maintain a comfortable temperature was reduced only about 25 percent. Furthermore, the plates were inconvenient because one of them had to be removed in order to add wood, and I was apprehensive that a malfunction in the Heatilator fans might allow the firebox temperatures to rise to dangerous levels. So the plates were used with caution.

Finally I decided to remove the entire fireplace and replace it with an airtight, cast-iron, wood-burning stove. This entailed a great deal of work, considerable additional cost, and made a mess in the living room. Our beautiful corner fireplace and chimney were dismantled brick by brick, but we now have approximately 1,000 clean bricks awaiting another use.

We think we did the right thing. With less than half as much wood, our cast-iron stove provides more effective heat

than the corner fireplace. This is mainly because the infiltration of cold outside air is vastly reduced. Also, a larger part of the stove heat comes from radiation, rather than from forced ejection of hot air, which tended to produce a concentration of warm air on the ceiling. Since no fans are involved, the stove uses no electricity and is silent. In addition, its operation is not subject to power failures. Less than half as much wood as before needs to be cut, hauled, stacked, and fed to the fire, and less than half the quantity of ashes needs to be removed. During winter, the stove fire is typically kept burning continuously for several days or even a week between mild spells, and is stoked only three times a day—in the morning before I leave for work, in the evening when I return, and just before retiring. The blanket that formerly hung in the hallway is now only rarely used. Our use of the propane stove in the old part of the house has been reduced by virtue of the wood stove because cold air does not enter that part of the house around the edges of the blanket. Except on a few rare occasions, we turn off the one propane stove in the dining room before retiring, and a slow fire in the wood stove maintains a comfortable sleeping temperature throughout the night.

When our corner fireplace was in use, we found that substantial temperature differences developed between floor and ceiling. Therefore, with the advice and assistance of a neighbor, I installed a six-inch-diameter duct that ran from just under the living room ceiling, down a closet wall, and then horizontally under the floor. A fan below the living room ceiling drew warm air off the ceiling and blew it through the duct to a vent in the living room floor. The living room was thereby made much more comfortable. Temperature differences are not as great with the cast-iron stove, but after the stove was installed I modified and extended the duct to transfer heated air from the living room to the old part of the house. By this means, the wood stove can be used more effectively to heat several rooms. Since the duct runs under the house, it is heavily insulated to preserve the warmth of the room air. If the duct had been placed in a paneled enclosure along the ceiling next to a wall, it would not have required insulation and would have been even more efficient than our under-the-house duct.

Heat loss through a floor can be large or small, depending on house construc-

The 1982 Program

Stimulate your mind on a Questers nature tour. We search out the plants and animals, birds and flowers...and explore rain forests, mountains and tundra, seashores, lakes and swamps. There is ample time to photograph, absorb, reflect. Naturalist guides, small tour parties, first-class accommodations.

New York, NY 10010 • (212) 673-3120

I'm right here in America– and I need you for a friend.

Annie is typical of many American Indian children who may not stay in school without the help you can give.

She's bright as a button. But her father can't find permanent work and her mother must care for brothers and sisters who live with her on an Arizona reservation.

Her family and tribe are proud of Annie's progress in school and they want her to finish. And now, happily, she has a Futures sponsor—someone like yourself—who will help make it happen.

But there are many other Annies: school-age girls and boys on reservations who need your help.

Through Futures for Children you can sponsor one or more of them. Your contribution of $20 a month will buy new jeans, shoes, a warm coat for cold winters, personal items, school supplies, and much more. *And you'll enrich your own life in coming to understand a different culture—right here in the United States.*

So you don't have to look far to find a child who needs your help. You'll receive a picture of your Indian child, a personal history, and lots of information about life in Indian America. What a thrill to get that first letter from your Indian child! Write your check to Futures today. Please send it with the coupon below.

_____ I want to sponsor an American Indian child ☐ boy ☐ girl ☐ either
Enclosed is a check for $_____ ($20 monthly, $60 quarterly, $120 semi-annually, $240 annually)
_____ Can't be a sponsor now, but I'd like to help your program. Enclosed is my tax-deductible donation of $_____ NH1081
_____ Send me more information about sponsoring an American Indian child
_____ Let me help your community program for Indian parents. Here is my contribution of $_____ and please send me more information.

THE FAMOUS ENGLISH BOBBY WHISTLE NOW AVAILABLE IN AMERICA!

Scotland Yard uses it to blow the whistle on crime you'll use it for safety to hail cabs even as a fashionable pendant! Hang on your keychain, too!

This is the very same whistle issued to Scotland Yard and the English police. In many instances, it is the only weapon they carry. Yet the whistle's shrill warning is enough to send shivers down a criminal's spine. Carry it to and from work for safety's sake. Keep one in the glove compartment of your car. And there are other practical reasons for owning one. It's a great way to hail a taxi, keep track of kids at the beach or hiking. And it even makes a fashionable pendant! Nickle-plated brass. At only $4.98 can you afford not to own one?

One for $4.98 plus 65¢ postage & handling. Two for $8.88 plus $1.10 postage and handling.
(NY residents add sales tax)

tion. Floor losses are small in Oklahoma in homes built on slabs because the ground here is warm, even in winter. (The average annual ground temperature in central Oklahoma is 60°F, compared to the average of 50° near New York City.) When a house is built on fieldstone, as ours is, and has a crawl space under the floor, as ours has, heat loss through the floor depends on insulation and on the temperature in the crawl space. Since the fieldstones of our house foundation are only loosely cemented, there was a strong draft of cold air under the house on windy winter days. Previous owners had reduced the draft by placing bales of hay along the foundation on the north side of the house. I discontinued this practice because I considered it a fire hazard. Instead, I went to some effort with sheet metal and plywood to seal the exterior of the foundation, and our new siding, which extended over most of the foundation, also helped.

The floor area of a one-story house is about one-half to three-fourths the wall area from floor to ceiling, and after the improvements, I estimated the heat loss through the uninsulated floor to be about a third of that through the original uninsulated walls, excluding windows. Finally, I insulated the floors by stapling lengths of fiberglass between the floor joists. Owing to restricted crawl space, the task was difficult, but the results were gratifying. The floor temperature inside the house rose noticeably, and temperature differences and drafts from room to room within the house were further reduced. Insulating the floor substantially increased our comfort while further reducing the energy required to heat the house.

I have made several solar energy devices that contribute to our comfort while reducing our energy bills. The south-facing wall of our small TV room-guest bedroom-daytime lounge is only slightly obstructed in winter by leafless black locust trees, and so is used as the collector surface for a solar heater. This heater is little more than a frame of 2″ by 4″ lumber attached to the exterior wall and covered with a fiberglass reinforced panel that transmits nearly all of the light incident upon it. At the lower east end of the collector is a four-inch-diameter hole through which a 14-watt fan blows air from the floor of our dining room. The air returns to the guest bedroom through a four-inch hole in the wall at the upper west end of the collector. The vertical orientation of the col-

lector provides for automatic cutoff in the warm season when the sun rises and sets toward the north and passes nearly through the zenith. On a clear winter midday, this heater typically produces a temperature rise of 60 degrees (from 60° to 120°) in air flowing at a rate of seventy-five cubic feet per minute; this represents more heat than is delivered by a one-kilowatt electric heater. On practically all sunny winter days the solar heater alone assures comfort in the 8′ by 10′ room it serves, and while it is in operation, the propane stove in the adjoining dining room is either turned down very low or turned off. With the use of some recycled components, this solar heater was built for less than $100.

The economic effects of our conservation efforts are illustrated by data on our use of propane and electricity, especially in relation to the expansion of facilities on my farm. When my wife and I moved into our farmhouse in September 1974, it comprised 850 square feet. We added 650 square feet during 1975. In 1976, we built a 720-square-foot guest cottage and we have also installed new irrigation and refrigeration units. Propane deliveries were 905 gallons in 1975, partly a result of heavy usage during 1974. In 1979, following the coldest winter on record in central Oklahoma, when temperatures from December 1978 through February 1979 averaged about 31°, as compared with the usual 39°, 736 gallons of propane were delivered; in 1980, only 330 gallons. Annual usage of electricity was 8,070 kilowatt hours in 1975, and peaked at 9,515 kilowatt hours in 1977. During 1980, usage was only 7,509 kilowatt hours, in spite of a summer even hotter than the hottest of dustbowl days, with temperatures averaging near 88° instead of about 82° and requiring heavy use of fans, refrigerators, and water pumps. Our use of electricity and propane in 1981 up to this writing has continued at satisfactorily low levels. And since we installed the woodburning stove, we have, of course, used wood—about two cords per year. (Summer usage of electricity has been kept low by means of evaporative coolers and solar devices.)

With electric bills of approximately $30 per month and expenditures of about $200 per year for propane, our energy costs are substantially below those of less energy efficient houses; at the same time we are living in as much, or perhaps even more, comfort than most people. □

What your home could have in common with the Met, the Tate, and the Louvre.

Helen Rundell's *Shelter Island*, original lithograph. Signed limited edition of 175.

Beautiful, original works by artists who are represented in the world's great museums and galleries can be yours for very reasonable prices.

We offer original etchings, lithographs and serigraphs signed by Calder, Chagall, Dali, Miró, Renoir, Vasarely and other important artists.

Helen Rundell's serene lithograph, *Shelter Island*, is one of the many fine prints we've made available.

Our expert advice and full money-back guarantee are your assurances that the art you buy will have lasting value and beauty.

Save Your Fireplace!

Those crackling flames can lift your spirits, but your open fireplace actually *wastes* more heat than it delivers. Perhaps you've discovered that tubular grates, glass doors and ordinary fireplace inserts offer only a partial solution at best. Yet a black metal woodstove on your hearth would be an affront to your room decor.

Efficiency on wheels

The Shelburne can transform your fireplace into a super-efficient heat producer without compromising the visual and soul-warming pleasures it provides. You enjoy a visible fire behind safe Corning Pyroceram glass. Downdraft combustion, 2000°F space-capsule insulation and a 40" baffle system help account for its amazing performance. And the Shelburne *rolls out* on your hearth for easy chimney cleaning.

The Shelburne Fireplace-Stove

(A) Doors may be opened to view the fire (B) Air is preheated as it enters downdraft and secondary air tubes (C) Firebrick-lined ¼" steel firebox (D) Automatic thermostat (E) Pullout ash pan (F) Fan with speed control (G) 40" baffling system (H) Flanges in choice of 3 widths permit installation in over 80% of all fireplaces.

Indoor Air Pollution

Your cozy fireplace may involve risks you do not know about

by Colin High

If you live in a cold climate, where frigid night winds blow in one side of your house and out the other and your heating bills make you think you must be heating the whole outdoors, you probably realize a wise move would be to fill in the cracks and cut down on the drafts in the house. There is no doubt that for the average older home, reducing the air-infiltration rate, by caulking, weather-stripping, and installing storm doors and windows, is the most cost-effective way of reducing winter heating bills. In areas of high heat costs in the northern states, many kinds of weatherproofing repay their expense in one or two heating seasons.

But as more and more homeowners wisely save energy by sealing up the cracks in their houses, another problem is giving them cause for concern, namely, indoor air pollution. A house may contain numerous potential sources of gaseous and particulate air pollution, such as smoke and/or particles from cigarettes, a working fireplace, a wood-burning stove, or a gas cooking stove. As the rate of air exchange between the inside and the outside of the house is reduced, the possibility that some or all of these pollutants will accumulate is increased.

Indoor air pollution is not a new phenomenon. On the contrary, today's houses are probably far more healthful than those of a century ago, when open fires and poorly ventilated coal- and wood-burning cookstoves created high levels of indoor air pollution. In particular, housewives working in the kitchen may have been exposed to more than their fair share of pollution. The quality of the air in pioneers' huts, Indian tepees, and sod houses, which were often built without chimneys, was certainly far worse than the quality of the air found in modern houses. Fortunately, the inhabitants of the earlier structures spent a good deal of their time outdoors. Today, however, much more time is spent indoors, especially in the winter, and young children may spend most of their time inside the house.

The problem of indoor air pollution has only recently been recognized. That recognition began when skyrocketing fuel prices drove homeowners to employ energy conservation measures that, in turn, often reduced the air-exchange rates in the houses. The open fireplace, the traditional heat source and symbol of warmth, comfort, and hospitality, is probably the most serious cause of indoor air pollution. Wood and coal fires release high concentrations of very small particles, including ash and unburned hydrocarbons. The most worrisome of these particles are the small polycyclic organic materials, known as POMs, whose molecules are arranged in rings. The general class of POMs includes more than a thousand identifiable organic compounds found in wood, coal, and cigarette smoke, and in auto and truck emissions. Many of these POMs, such as those from wood, coal, and cigarette smoke, have been found to be carcinogenic and therefore a serious cause for concern. Tests in some typical American homes with working open fireplaces show that concentrations of particulates, which include POMs, may be four or five times higher than they are outdoors. Wood stoves of the airtight variety, with controlled airflow and properly installed chimneys, release fewer particles into the house than fireplaces and, in consequence, are a less serious source of harmful indoor pollution. Considering that most Americans view an open fireplace as a desirable feature, it is ironic that this symbol of coziness has so little to recommend it from the point of view of health. Not only are fireplaces a serious source of indoor air pollution but they may also be

An airtight wood-burning stove, equipped with a properly installed chimney, releases fewer particulate pollutants into the interior of a house than an open fireplace does.

Robert Perron

a fire risk and burn hazard for children. In addition, the efficiency of open fireplaces is only one-third that of woodstoves. In very cold weather, an open fireplace operating at the same time as a conventional central heating system may actually draw more hot air up through the chimney and out of the house than the amount of heat it replaces by radiation.

Cooking on a gas stove produces both gaseous and particulate air pollutants. The good smells that emanate from the kitchen stove and draw the family around the dining table may be accompanied by other, less desirable vapors. There are two potential sources of pollution at the kitchen stove: the cooking or burning of food and the gas flames used for cooking. The process of cooking food releases gases and particles that include small quantities of POMs. Only occasionally, however, are the POM concentrations high enough to cause alarm, as when the burning of food creates a pall of blue smoke hanging below the ceiling. Of greater concern are the emissions of carbon monoxide and nitrogen oxides from gas cooking. Tests show that in some kitchens equipped with gas stoves, the level of nitrogen oxides may be five times higher than the level outdoors, and carbon monoxide levels are also higher. Both nitrogen oxides and carbon monoxide—caused outdoors primarily by motor vehicles—are recognized by the Environmental Protection Agency as serious pollutants that give rise to both acute and chronic health problems. There are, however, no national air quality standards for private homes. In houses where tests have been made, the federal ambient air quality standards for outdoor air are sometimes exceeded for particulates, nitrogen oxides, and carbon monoxide, even though the outdoor air quality has met the federal standards. These increased indoor air-pollution levels are largely attributed to open fireplaces, gas cooking, and cigarette and cigar smoking.

Air pollution from smoking is highly variable, and the subject is, of course, controversial. Cigarette smoke produces particulates, such as hydrocarbons and POMs, and is responsible for increased particulate levels inside private houses, offices, and public buildings. Due to the absence of open fires and cooking facilities, however, the air quality in offices and public buildings is usually better than that in homes and sometimes even better than that in the streets. Furthermore, most offices and public buildings have better ventilation and air-filtration systems than the average privately owned house.

Although particulates, carbon monoxide, and nitrogen oxides are the most common home pollutants, there are others that may also be a cause for concern. Painting, cleaning, and the projects carried out in home workshops often involve the use of volatile organic solvents that are components of paints, thinning agents, cleansers, and glues. The con-

Installing storm windows and siding serves to cut home heating costs, but as the rate of exchange between inside and outside air is reduced, indoor air pollution can become a real problem.

tainers for these products warn users about the need for adequate ventilation, but that may be hard to provide in winter. Because many of these solvents are toxic and carcinogenic, they represent some degree of health hazard even though we do not yet know how serious occasional exposure to them may be.

Gaseous and particulate pollutants from gas stoves, cigarette smoke, cooking food, and other sources can accumulate in houses where caulking and weather-stripping prevent the leakage of indoor air.

Exposure to the fumes of various solvents is infrequent and the incipient pollution can be recognized by the smell; the problem presented by radon gas in the home, however, cannot be so easily dismissed. Radon, which is released by radioactive minerals, can enter private homes in very small quantities from rock basements and masonry materials used in construction. Odorless and colorless, radon cannot be detected by the occupants. The long-term health effects of exposure to trace quantities of radon gas are not known with certainty; nevertheless, there is reason to believe that exposure to this radioactive gas increases the risk of cancers. Most at risk are occupants of poorly ventilated homes with exposed rock or masonry

A Gift for Health

NordicTrack

Jarless Total Body Cardiovascular Exerciser

Duplicates X-C Skiing for the Best Motion in Fitness

Highly Effective and Pleasant To Use
The enjoyable sport of cross-country skiing is often cited as the most perfect form of C-V exercise. Its smooth, fluid, total body motion uniformly exercises more muscles and higher heart rates seem easier to attain than when jogging or cycling. NordicTrack closely simulates the same pleasant motion and provides the same cardiovascular endurance-building benefits — right in the convenience of your home. Makes a year round, consistent exercise program easily attainable. Eliminates the usual barriers of time, weather, chance of injury, etc. Also highly effective for weight control.

Better Than Running
NordicTrack gives you a more complete work out — conditions both upper body and lower body muscles at the same time. Fluid, jarless motion will not cause joint or back pains as jogging or running often does.

Better Than Exercise Bikes
NordicTracks stand-up skiing motion more uniformly exercises large leg muscles and also adds important upper body exercise. Higher pulse rates, necessary for building fitness, seem easier to attain because the work is shared by more muscle mass. The NordicTrack also keeps more muscles in tone.

Even Better Than Swimming
NordicTrack more effectively exercises the largest muscles in the body, those located in the legs and buttocks. These muscles main function is to lift and propel the body in the standing position. When swimming, the water supports the body thus preventing these muscles from being exercised as effectively as when they support the body in a standing position.

A Proven, high Quality Durable Product
Ruggedly constructed, NordicTrack is quiet, motorless and folds compactly for storage. Separate arm and leg resistances. NordicTrack is in its 5th year of production and is used in thousands of homes and many companies. We manufacture and sell direct. Our No-Risk 15 day trial guarantee shows our confidence in your being pleased with the performance and quality of the NordicTrack.

This year, give someone you love a gift for better health.

basements built in areas of granitic or other igneous and metamorphic rocks.

Solutions to the problem of indoor air pollution are not difficult and are generally not unduly expensive. Proper ventilation is essential in all houses, even in winter. Specific sources of pollution can be dealt with individually. The solution to smoking is clear. Even if nobody in the household smokes, dealing with guests who do—and especially with large parties—requires tact and diplomacy. Perhaps the easiest solution is just to open the windows wide when smokers are present and hope your hospitality will keep everyone warm. The use of solvents really does require adequate ventilation. Painting and cleaning that depend on solvents should be reserved for warm weather, when windows and doors can be opened. Because radon gas is difficult to detect, preventive action is the best cure. Good ventilation and basement walls made of sealed or painted concrete should reduce or eliminate the buildup of radon gas within the home.

Eliminating pollution derived from cooking and from open fires presents harder choices. Giving up an open fireplace may be difficult for some people. Installation of a fireplace insert, which is like a stove fitted snugly into a fireplace opening and closed with metal or heavy glass doors, would enhance the heat from the burning firewood and reduce the amount of indoor air pollution. Wood or gas cooking stoves need adequate hoods and forced draft ventilation to the outside to prevent the buildup of pollutants, especially during the winter when most homes are sealed up against the cold. Other gas- or oil-burning appliances, such as furnaces and hot-water heaters, must also be adequately vented to comply with building codes. As energy costs rise, however, the need to conserve heat in the house and

As buildings of all kinds become better insulated and more airtight, effective ventilation systems will be required to control the quality of indoor air.

maintain good ventilation will probably mean increased home use of air–heat exchangers similar to those now used in some offices and public buildings.

Air–heat exchangers operate by blowing hot air out of, and sucking cold air into, a building. The exchanger is a box, about the size of an average window air conditioner, that is installed in a ventilation system. One motor in the exchanger drives a fan that blows hot air out over a partition made of treated paper or plastic; a second motor drives another fan that blows cold air in from the outside over the same partition. The partition separates the two airflows in such a fashion that heat from the indoor, used air is transferred to the incoming, cold air. The trick is to design the exchanger so that the heat can be transferred without transferring the indoor pollutants to the incoming air.

A number of air–heat exchange units for home use are now on the market. Some of these units are imported from Japan and Europe where high-cost energy has made home heat conservation as essential as it is fast becoming here. □

Exotic cinnabar egg makes extraordinary accent piece.

Exquisitely crafted cinnabar egg from Willoughby & Taylor's collection of world treasures makes an extraordinary accent piece or special gift. Created by careful layering of Chinese cinnabar lacquer, and accentuated by masterful carvings of Oriental characters and delicate flowers, it conveys a most exotic quality. Speak French like a diplomat!

What sort of people need to learn a foreign language as quickly and effectively as possible? *Foreign service personnel*, that's who. Members of America's diplomatic corps are assigned to U.S. embassies abroad, where they must be able to converse fluently in every situation.

Now *you* can make a start on learning to speak French just as these diplomatic personnel do—with the Foreign Service Institute's Basic French Course.

The U.S. Department of State has spent tens of thousands of dollars developing this course. It's by far *the most effective way* to learn French at your convenience and at your own pace.

The Basic French Course consists of a series of audio cassettes and an accompanying textbook. You simply follow the spoken and written instructions, listening and repeating. By the end of the course you'll find yourself learning and speaking entirely in French!

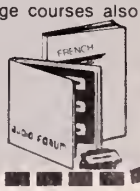
This course turns your cassette player into a "teaching machine." With its unique "pattern drill" learning method, you set your own pace—testing yourself, correcting errors, reinforcing accurate responses.

The FSI's Introductory Basic French Course comes in two parts. Part A provides an introduction to the simpler forms of the language plus a basic vocabulary. Part B introduces more complex structures and additional vocabulary.

You may order one or both parts of the Basic French Course:

☐ Basic French, Part A. 12 cassettes (17 hours) and 200-page text, $115.

☐ Basic French, Part B. 18 cassettes (25½ hours) and 300-page text, $149.



(New York State residents add sales tax)

Your cassettes are shipped to you in handsome library binders.

TO ORDER, JUST CLIP THIS AD and mail it with your name and address and a check or money order. Or, charge to your credit card (American Express, VISA, Master Charge, Diners Club) by enclosing card number, expiration date, and your signature.

The Foreign Service Institute's French course is *unconditionally guaranteed*. Try it for three weeks. If you're not convinced it's *the fastest, easiest, most painless way to learn French*, return it and we'll refund every penny you paid! Order today!

Many other FSI language courses also available. Write us.

Transparent Solutions

by J. Max Bond, Jr.

THE GLASS HOUSE, by John Hix. *The MIT Press, $9.95 (paperback); 208 pp., illus.*

During the eighteenth and nineteenth centuries, as the needs of plants came to be better understood, systems for heating and ventilating structures used for growing plants evolved rapidly. Concomitantly, plant houses, derived from the "wintering sheds" equipped with braziers to provide a little extra heat for plants grown inside in winter, gradually became more transparent. In the nineteenth century, in particular, the skills required to make glass enclosures developed enormously, to the point that by mid-century the technical skill existed to create such masterpieces as Joseph Paxton's London Crystal Palace (1851), Richard Turner's Palm House at Kew (1845–48), and the Crystal Art Palace in Queen's Park, Glasgow (1873). By 1889, the huge Galerie des Machines, built for the second Paris Universal Exhibition, had been completed.

Their very names suggest the aura that surrounded these tremendously popular structures. The London Crystal Palace was huge, yet it was executed in less than a year—a feat, notes author John Hix in *The Glass House*, of "mass-production, prefabrication, standardization, modular construction, systems-integration ... and ingenuity."

Hix strongly believes that the great technical achievements of the nineteenth-century building industry, which fostered creativity and original solutions to new building problems, can be replicated in our own time, and beyond, in addressing such problems as the reclamation of arid lands, feeding the world's poor, and the energy crisis. Thus, each of the two sections of his book ends with a scheme for the future. The first section, generally about the control of internal climates, concludes with a description of an integrated desert plant house that, while growing vegetables, produces fresh water from salt water. The second section ends with illustrations of a covered arctic city—a finale that reveals quite a bit about the author's purposes and orientation. For despite his obvious appreciation of the beauty of the great glass conservatories, which are amply documented here, Hix's primary concerns are with utility and the solving of problems.

The Glass House focuses on a particular type of glass building: not the church, not the commercial galleria, not the alienating glass tower, but instead the useful (for growing plants), delightful (on a dreary winter day), popular conservatory or exhibition hall favored by the nineteenth-century positivist Western society. The structures featured in the book resulted from increased world trade and the Industrial Revolution. They were created at a time when, as Hix says in his introduction, European society was concerned with "man's growing ability to use the forces of nature." It was a time, too, when technology was still mechanical, visible, and tactile.

The book's themes are developed through both the text and the extensive and fascinating illustrations. One problem with this arrangement, however, is that the text and illustrations often compete for the reader's attention. Still, to some degree, they work together suggestively in that the text is all technology and logic while the buildings shown are often quite sensual in form. At one point, the author tells us that in designing the Crystal Palace, Joseph Paxton developed a floor-cleaning machine that turned out to be unnecessary because the long skirts worn by Victorian ladies swept the floors. As a counterpoint, the pictures convey an image of "properly" dressed and mannered people promenading through an Eden of lush and exotic vegetation.

While the material presented in *The Glass House* is fascinating, the style of its presentation is less than vivid. This seems to stem not only from the conflict between the text and illustrations but also from the organization. The treatment is not chronological: one part of the book deals with environmental-con-

Fern House at Ashridge, by Matthew Digby Wyatt

trol systems and horticulture; another covers the making of the enclosures; and yet other sections describe various types of glass buildings. Consequently, the relationships between people who figured prominently in the unfolding glass drama are difficult to grasp and the cross-fertilization of ideas is difficult to follow. In reading the book, one recalls other works on building, such as *The Great Bridge*, about the construction of the Brooklyn Bridge. That work, although deliberately aimed at a lay audience, also manages to engage the informed reader. Hix's work does not.

There are various subthemes, almost asides, which might have made his effort more compelling had they been developed. Readers learn that at one time the purchase of glass was taxed, and that when the tax was rescinded, glass became much cheaper and, so, more popular. Well, this reader would have liked to know more about this and other aspects of the *context* in which glass buildings evolved. We are told that

there was intense competition to secure the commission to build the Crystal Palace; although a few details about the maneuvering that went on are given, we learn nothing about the people involved. Various powerful figures are mentioned, but too little is said about them and their intentions, as in the case of Richard Turner, one of the era's foremost engineers. He constructed the beautiful Palm House at Kew, sometimes competing, and at other times cooperating, with the architect, Decimus Burton. More detailed examination of their interaction could have told us something about the attitudes and dynamics that generated some quite marvelous building designs.

On the other hand, Hix covers a lot of ground in his attention to the development of productive greenhouses, the mastery of climate control, the industrialization of building, the conservation of energy through the use of solar power, and the creativity associated with an orientation toward solving problems through technology. And he addresses a few of the many architectural issues that are germane to the evolution of glass buildings. The private conservatory, he observes, gained popularity, in part, because of changes in the uses of the middle-class house, which had once combined the functions of both home and workplace. As the house became increasingly a place for leisure and entertainment, the conservatory was conceived to enhance those new functions. In 1850, W. Bridges Adam, in describing the criteria that should govern the building of the Crystal Palace, virtually coined what became, a half century later, the slogan of functionalism: "form follows function." (Some of the early glass buildings described in the book are prophetic, foretelling such futuristic designs as Buckminster Fuller's Dymaxion House or James Stirling's marvelous work at Leicester.) Later, the author hints at the current critique of the functionalist position by quoting John Ruskin, who in discussing the Crystal Palace questions whether the solving of technical problems is enough to constitute meaningful architecture. Hix also touches on the dilemma arising out of a technocratic position. While the conservatories and exhibition halls of the nineteenth century were beautiful and were built to promote nature, their ultimate extensions—as expressed in Buckminster Fuller's plan to cover part of New York City with a glass dome and later proposals for plastic-covered arctic cities—suggest, rather, an alienation from nature. We may enjoy visiting the rebuilt Enid D. Haupt Conservatory at

UNIQUE TURNER OFFER

A First Rate taking in Stores
Signed "J M W Turner 1818" (19 x 17 in.)

Superb quality print of a very beautiful Turner watercolour. Art historian B.L. Binyon wrote in 1909 "This is Turner at the peak of his powers, his palette is positively translucent." The original is in a private collection in England, and has rarely been seen since 1819, when it was exhibited at Grosvenor Palace.

A few hundred copies were printed to commemorate Turner's bicentenary. We have every one of them. There will be no more available once these few are gone.

The Victoria Regia house in Leyden

the New York Botanical Garden, but would we really want to live in a domed New York or under a bubble on the banks of the Mississippi, as Fuller has also proposed? Does it make sense to create a technologically advanced structure just because it can be done or should other principles guide us? The nature of the ground covered lends to Hix's book the character of an illustrated history, a primer on solar energy and the virtues of integrating greenhouses with urban life, and a functionalist's commentary on the evolution of architectural style.

Is it contradictory to say that a book seeks to be too many things, while also saying that the author should have attempted more? I think not—if certain additions would have clarified the format and provided a more solid basis for the reader to assimilate the material, thus enriching the reading experience. Hix's range of concerns is broad, and admirably, he acknowledges the relationship of building as a practical art to economic and social factors, but in the final analysis one wonders whether his strong emphasis on the practical aspects of glass building is not a limitation. This preoccupation perhaps explains his neglect of two of the most significant aspects of glass construction. Yet light is discussed here in regard to its practical qualities rather than its architectural ones—light for warmth and as illumination for the nurturing of plants, not light as an organic and evocative element of architecture. Thus, the Gothic cathedrals, in which light was used to aid in the conjuring of a mystical environment, are not mentioned.

Leyden University Library Collection

Second, the transparency of glass has the effect of integrating man with nature (as exemplified in, say, Mies van der Rohe's Farnsworth House), but this dimension of glass construction receives only passing mention. Moreover, the gridded, abstract exteriors, which the discipline of making a glass skin achieves in its repetition of many relatively small pieces and joints, have led architects to explore minimalist notions about building and form. The short shrift given these aspects of glass construction tends to rob readers of some potentially enlightening discussion.

During the mid- to late-nineteenth century, there were significant developments in several of the artistic disciplines. In painting, the Impressionists were experimenting with light and solidity—the same elements, in a sense, that were commanding the interest of architects in designing the buildings cited by Hix. Certain visual discoveries led to changes in the way the world was perceived, thereby altering the course of modern art and architecture. A discussion of the architecture of light and transparency in *The Glass House* would not only have been in order but would also have been especially rewarding in the context of what was happening in other art media at the time. By merely touching on the potential of glass and its corollary, light, in a rather brief discussion of the Expressionist architecture of the twentieth century, Hix appears to grant the glass building, with its wonderfully intricate space and light interplays, less than its full status in the history of architectural expression.

Had he chosen a larger frame of reference, relating economic, social, personal, and aesthetic issues to his investigation of one building type, Hix might have made of his excellent documentation a more profoundly enlightening work.

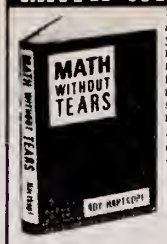
The Science—and Art—of Keeping Warm



Historical Perspective

Some books dealing with the relationship of climate to design are: R. Banham's *The Architecture of the Well-tempered Environment* (Chicago: University of Chicago Press, 1969); J.M. Fitch's *American Building* (Boston: Houghton Mifflin, 1972); B. Givoni's *Man, Climate and Architecture* (Amsterdam: Elsevier, 1969); and V. Olgyay's *Design with Climate* (Princeton: Princeton University Press, 1963). W. Hough's *Fire as an Agent in Human Culture* (Washington, D.C.: Smithsonian Institution, Bulletin No. 139, 1926) is a fundamental work on the making, conservation, and application of fire in nonindustrialized populations. K.P. Oakley wrote several important articles on the prehistory of fire, including "Possible Origins of the Use of Fire" (*Man*, 1961, p. 207) and "Fire as a Palaeolithic Tool and Weapon" (*Proceedings of the Prehistory Society*, vol. 21, pp. 36–47).

People

In his sensitively written *Japanese Homes and Their Surroundings* (New York: Dover Books, 1961), E.S. Morse describes the structural and cultural aspects of the Japanese home at a time when Japan had experienced little Westernization. See also T. Yoshida's *The Japanese House and Garden* (New York: Praeger, 1955) and B. Rudofsky's *The Kimono Mind* (Garden City: Doubleday, 1965). S. Shōnagon served as a lady-in-waiting at the royal court during the last decade of the tenth century. Her vast collection of notes detailing her life during this time forms *The Pillow Book of Sei Shōnagon*, translated and edited by I. Morris (New York: Columbia University Press, 1967, two volumes), a rich source of information about traditional Japanese upper-class life. The earliest accounts of the Eskimos, their houses, clothing, tools, and weapons are by G. Best and D. Settle. Works by these authors are reprinted in V. Stefansson's two-volume *The Three Voyages of Martin Frobisher* (London: Argonaut Press, 1938). Stefansson wrote in great detail about the Eskimos' adaptation to cold, most notably in *The Friendly Arctic* (New York: Macmillan, 1921), *My Life With the Eskimo* (New York: Macmillan, 1913, reprinted in paperback by Collier Books, New York, in 1962), and *The Fat of the Land* (New York: Macmillan, 1956). *The Central Eskimo*, by F. Boas, published in 1888 and reprinted in paperback by the University of Nebraska Press, Lincoln, in 1964, is a classic and comprehensive account of Eskimo life during the 1880s. A more modern account of one of the most isolated Eskimo groups, containing precise information about Eskimo technology, is A. Balikci's *The Netsilik Eskimo* (Garden City: Natural History Press, 1970). A recent, excellent summary of Eskimo prehistory, dealing also with Eskimo prehistory in Alaska and Greenland, although only briefly, is R. McGhee's *Canadian Arctic Prehistory* (Ottawa: National Museum of Man, 1978). Cold, its effects upon humans, and how humans have tried to cope with it are the subjects of L. Kevaler's very readable *Freezing Point* (New York: John Day Co., 1970). Similarly specialized is R. Kirk's *Snow*, an easy to read, well-researched book with an excellent and extensive bibliography that deals in detail with the Eskimos' use and knowledge of snow as an insulating material. For a scholarly treatment of the Eskimos' physiological and cultural adaptations to the rigors of their homeland, see E.F. Morani's *Human Adaptability*

MATH WITHOUT TEARS

Using non-technical language and a light touch Roy Hartkopf gives you a basic understanding of many everyday applications of mathematics. He takes the reader from simple counting to trigonometry and calculus, emphasizing the practical aspects of math. Humorously written.
Learn math in the comfort of your own home at minimum cost.

(North Scituate: Duxbury Press, 1979). Two books by F. Bruemmer are *The Arctic* (New York: Quadrangle/The New York Times Book Co., 1973), which covers the adaptation to cold by arctic plants, animals, and northern people, and *Seasons of the Eskimo* (New York: New York Graphic Society, 1971), which records the seasonal cycle of Eskimo life and cultural adaptations to the severe climate.

Animals

S.C. Kendeigh's "Energy of Birds Conserved by Roosting in Cavities" (*Wilson Bulletin*, vol. 73, pp. 140–47) discusses how birds use this strategy to save energy and maintain higher temperatures during periods of extreme weather. Articles on energy-saving techniques of black-capped chickadees include B. Kessel's "Winter Activity Patterns of Black-capped Chickadee" (*Wilson Bulletin*, vol. 88, pp. 36–61) and S.B. Chaplin's "Daily Energetics of the Black-capped Chickadee" (*Journal of Comparative Physiology*, vol. 89, pp. 321–30). L. Irving's *Arctic Life of Birds and Mammals, Including Man* (New York: Springer-Verlag, 1972) includes chapters on arctic environment, land birds and their migration, maintenance of arctic bird populations, and warm temperatures of birds and mammals. In "Physiology of Hibernating Bears," G.E. Folk, A. Larson, and M.A. Folk consider whether the term *hibernation* is justified, and review all the conspicuous papers on the subject (*Bears: Their Biology and Management*, edited by M.R. Pelton, J.W. Lentfer, and G.E. Folk. New York: Unipub, New Series Publications no. 40, 1976). R.A. Nelson reviews the physiological and metabolic processes involved in hibernation in "Winter Sleep in the Black Bear" (Rochester: Mayo Clinic Proceedings 48, pp. 733–37). L. Rogers summarizes in six nontechnical pages his knowledge of bears, including how they relate to people, denning, and cub behavior, in "The Ubiquitous Black Bear" (*North American Big Game*, edited by W.H. Nesbitt and J.S. Parker. Washington, D.C.: The Boone and Crockett Club and the National Rifle Association of America, 1977). B. Ford's *Black Bear: Spirit of Wilderness* (Boston: Houghton Mifflin, 1981) is a scholarly, up-to-date general book with a good section on hibernation. P.D. Watts et al. propose a new definition of hibernation in "Mammalian Hibernation and the Oxygen Consumption of a Denning Black Bear" (*Comparative Biochemistry and Physi-*

Have More Fun With
HANDGUIDE TO THE CORAL REEF FISHES

. . . the most comprehensive, beautifully illustrated and accurate guide available for snorklers, divers and fish hobbyists. Shows 460 species in full color, along with 50 different corals, invertebrates and plants. For the beginner as well as the advanced student. Has easily-understood descriptions, useful hints on fishwatching, and unique checklists for quick identification.

Plants

Coevolution of Animals and Plants, edited by L.E. Gilbert and P.H. Raven (Austin: University of Texas Press, 1975), is a collection of ten papers, emphasizing the importance of coevolution as a dynamic process. The volume attempts to cover, as broadly as possible, all of the ways plants interact with animals. D.M. Gates's "The Energy Environment in Which We Live" (*American Scientist*, vol. 51, pp. 327–58) describes the radiant heat loads of plants and animals and the mechanisms for dissipating a heat load, and analyzes the energy budget and its diurnal temperature cycle. P.K. Kevan's "Sun-tracking Solar Furnaces in High Arctic Flowers" (*Science*, vol. 189, pp. 723–26) explains how the flowers of two common High Arctic plants, which occur widely in arctic and alpine regions, maximize their small heat budgets by sun tracking and how insects that bask in them also gain heat. *Arctic and Alpine Environments*, a 999-page text edited by J.D. Ives and R.G. Barry (London: Methuen, 1974), provides a comprehensive summary of our present knowledge of alpine and arctic environments and identifies the gaps in our understanding. On a more popular level is *The Mountains*, edited by L.J. Milne and M. Milne (New York: Time Inc., 1962), which has an informative text and many color photographs, but contains some factual errors. Treatises on specific ecosystems discussed in this issue include: *An Arctic Ecosystem: The Coastal Tundra at Barrow, Alaska*, edited by J. Brown et al. (Stroudsburg: Dowden, Hutchinson and Ross, 1980); *Truelove Lowland, Devon Island, Canada: A High Arctic Ecosystem*, edited by L.C. Bliss (Edmonton: University of Alberta Press, 1977); *Geoecology of the Colorado Front Range: A Study of Alpine and Subalpine Environments*, edited by J.D. Ives (Boulder: Westview Press, 1980). See also K. Scherman's *Spring on an Arctic Island* (Boston: Little, Brown and Co., 1956), her popular account of her expedition to an island north of the Arctic Circle.

Clothing

A. C. Guyton's *Textbook of Medical Physiology* (Philadelphia: W.B. Saunders Co., 1976) is a standard reference that gives some information on the physiological problems experienced at high altitudes. For more information on clothing designed to protect from the cold, see L.H. Newburgh's classic

Physiology of Heat Regulation and the Science of Clothing (Philadelphia: W.B. Saunders Co., 1949), a technical but readable treatise. *Materials and Clothing in Health and Disease*, by E.T. Renbourn (London: H.K. Lewis and Co., 1972), treats a wide range of subjects from the anatomy and physiology of clothing to its history, psychology, and function. E.E. Stout's illustrated *Introduction to Textiles* (New York: John Wiley and Sons, 1970), often used as a college text, explains differences between various materials. The last chapter of L. Irving's *Arctic Life of Birds and Mammals, Including Man* (New York: Springer-Verlag, 1972) covers the historical use of clothing, the early shelters and clothing of the Eskimos, and adjustments to cold by urban dwellers and by natives of cold climates.

Housing

Insulation Manual: Homes and Apartments is designed to provide home builders, architects, and engineers with a complete source of reliable information on the proper use of insulation, its economics and benefits. To obtain a copy, send $10 to the National Association of Home Builders Research Foundation, P.O. Box 1627, Rockville, Md., 20850. *Energy Primer: Solar, Water, Wind and Biofuels* is available from the Portola Group, Menlo Park, California. A basic, nontechnical explanation of solar energy with a comprehensive bibliography, F. Daniel's *Direct Use of the Sun's Energy* (Westminster: Ballantine Books, 1964) has been reprinted several times. For additional construction and performance details concerning the heating devices described in "House Warming," send $4.00 in money order to cover costs of reproduction, postage, and handling to Great Plains Apiaries, Rt. 2, Box 137, Purcell, Oklahoma 73080. *Oldtown Folks*, by H.B. Stowe, edited by H.F. May (Cambridge: The Belknap Press of Harvard University Press, 1966), follows the text of the first edition published in 1869 and recaptures local traditions and life in early-nineteenth-century New England. D. Ludlum's *The Country Journal New England Weather Book* (Boston: Houghton Mifflin Co., 1976) contains chapters on various aspects of weather and historical accounts of remarkable weather phenomena with many early illustrations. F. White's "Stoves in Nineteenth-Century New England" (*Antiques*, September 1979, pp. 592–99) describes in detail the types of stoves introduced in the 1820s and 1830s. Two of the most important references on indoor air pollution are "Comparison of Indoor and Outdoor Quality" by D.J. Moschandreas et al. (Palo Alto: The Electric Research Tower Institute, March 1981, EI 1733), and E.T. Brookman's "Exposure to Pollutants From Domestic Combustion Sources: A Preliminary Assessment" (Research Triangle Park: EPA, 1980, no. 600/7-80-084). Other references include "Indoor Air Pollution in the Residential Environment," by D.J. Moschandreas et al. (Research Triangle Park: EPA, December 1978, no. 600/7-78-229); "Study of Indoor Air Quality," by W.A. Cote et al. (Research Triangle Park: EPA, 1974); "Carbon Monoxide Levels in Kitchens and Homes With Gas Cookers," by T.D. Sterling and A. Sterling (*Journal of the Air Pollution Control Association*, vol. 29, pp. 238–41); and "Cigarette Smoke in Closed Spaces," by V.R. Hoegge (*Environmental Health Perspectives*, vol. 2, pp. 117–28).

Thank Goodness for Flannel Sheets!
I Thought I'd "Freeze to Death"

When I went to England, I just knew it was going to be the trip of a lifetime. I had saved and planned for years. Then, out of the blue, I got a chance to spend a few days in an honest-to-goodness 13th Century castle on Ilkley Moor while I was in Yorkshire.

What I overlooked was the English idea of central heating. After I left London the weather suddenly turned shivering cold and wet. By the time I got to Denton Hall I was too tired and miserable to care about picturesque charm and history. All I could think of was how uncomfortable I was going to be in an old, drafty castle.

Sure enough, my room was *freezing*. But when I crawled into bed I was dumbfounded to discover how marvelously cozy it was despite the lack of heat.

There was a big, puffy down comforter on top. Underneath, the sheets and even the pillowcases were flannel. And not that flimsy, pilled kind we used to have at summer camp. They were luxuriously soft, thick real *English cotton flannel*.

I felt utterly pampered in plushy comfort. And I never slept better, because I wasn't buried under layers of heavy bedclothes.

Then and there I decided I was going to have sheets like that at home. What a great way to save on heating costs at night and still feel rich and special!

When I got back to the United States I soon learned that the flannel sheets in stores didn't feel or look the same at all. The polyester in them made such a difference.

Finally, I got so frustrated I went to Damart, a company in my home town, and suggested they sell real English flannel sheets and pillowcases. They loved the idea.

And that's how Agatha's Cozy Corner was born. We talked it over and added heavenly down comforters and some other things as well as the sheets. And now I'd be happy to send you my catalog. It's printed in color, and gives you the pictures and story of everything we sell. Just use the coupon for your free copy.

Celestial Events

by Thomas D. Nicholson

Moon October begins with an evening moon, a slim waxing crescent in the west just after sundown. It passes above Venus on the 1st, above Scorpius on the 3rd, and through Sagittarius (look for the eight stars of the "teapot") on the 4th and 5th. First-quarter moon is on October 6, full moon (in Aries, but well to the left of the vernal equinox) on the 13th, last-quarter (just below the twin stars of Gemini) on the 19th, and new moon on the 27th. In November, first-quarter is on the 4th, full moon (with perigee and spring tides) on the 11th.

Stars and Planets We had a sky full of evening stars in September, but the evening sky falls apart in October when Mercury, Jupiter, Saturn, and Pluto shift into the morning sky. The sole planet seen in the evening sky this month is Venus, and that is only because it is bright enough to stand out in the early twilight after sundown. Look in the west from about half an hour after sunset until just before dark. This isn't a good evening visit for Venus, however. The morning sky isn't much better. Only Mars is in good position, well up in the southeast by daybreak, but rather dim. Fortunately, it can be recognized near Regulus, the bright star of Leo, which it joins as a "twin" star late in the month. Even though they shift from the evening to the morning sky, the planets are still gathered in or near the constellation Virgo. The sun remains in Virgo all month (moving into Libra for November), along with Mercury, Jupiter, Saturn, and Pluto. Venus, Uranus, and Neptune are just east of Virgo. Venus is in Libra, but moves into Scorpius and then Ophiuchus. Uranus is in Libra and Neptune is in Ophiuchus; while Mars remains in Leo all month, just west of Virgo.

October 1: The moon passes well above brilliant Venus.

October 5: Saturn, in conjunction with the sun, enters the morning sky.

October 6: Mercury is stationary, poised for its retrograde (westerly) motion through the stars.

October 11: Look for the Square of Pegasus (four stars arranged in a box) above the gibbous moon. The moon is just below the vernal equinox (also called the First Point of Aries), but won't be in Aries until the 13th.

October 13: This is the night of the hunter's moon, the full moon of October, which appears full or nearly full and rises at or shortly after sunset for the next three nights.

October 14: Jupiter's turn to enter the morning sky comes today when it is in conjunction with the sun.

October 18: Mercury becomes a morning star today when it passes between the earth and the sun (inferior conjunction).

October 19: Mars has been moving east toward Regulus, in Leo. Today it passes above the star. Look in the southeast before dawn for the two objects.

October 21: The Orionid meteor shower reaches maximum this morning, at its best from 2:00 A.M. on. The shower is not particularly productive (about 25 meteors per hour), but some very bright meteors result from this swift stream, believed to be associated with Halley's comet.

October 22: The waning crescent moon passes Regulus and Mars and is visible in the morning sky.

October 25: Daylight time ends at 2:00 A.M.

October 26: Mercury resumes direct (easterly) motion.

October 31: The crescent moon passes Venus in the evening sky.

November 2: Mercury, at greatest distance east of the sun, is in good position in the morning sky. Look before sunrise below the star Arcturus.

November 5: There is a good chance to see Mercury today, just above Jupiter, rising in the east before the sun.

November 10: Venus is at greatest easterly elongation, but this is not a good evening configuration for the planet.

The autumn Star Map shows the sky from the mid-latitudes (40° N) of the Northern Hemisphere during the evening hours given below. To use the map, hold it in front of you vertically with the letter N at the bottom, and match the *lower* half of the map with the stars you see when you face north. As you face in other directions, turn the map to bring the corresponding compass direction to the *bottom* of the map when facing you. The stars move west continuously throughout the night. By morning (before dawn) stars on the western half of the map will have set, those on the eastern half will have moved into the west, and new stars (those of the spring evenings) will have risen in the east.

The map represents the sky at about 2:00 A.M. on October 1; 1:00 A.M. on October 15; midnight on October 31; 11:00 P.M. on November 15; 10:00 P.M. on November 30; 9:00 P.M. on December 15; and 8:00 P.M. on December 31. Add one hour for daylight time. The map can be used for an hour or more before and after the times given.

Brain Puzzler's Delight

By E. R. Emmet

A treasury of unique mind-stretching puzzles that can be solved by straight, logical thinking and reasoning. No specialized math. Offers the pleasures of discovering solutions through use of ingenuity, imagination, insight, and logic. Stimulates and refreshes the mind. The Margaret Mead Film Festival

The fifth annual Margaret Mead Film Festival will be held at the American Museum on Saturday and Sunday, October 17 and 18. More than forty films will be presented. Many are premières, including David and Judith MacDougall's *A Wife Among Wives*; Robin Lehman's *Little Players*; Allen Moore and Jack Shea's *The Shepherds of Berneray*; *Village of No River*, by Stuart Hersch; and many others.

Films will be shown from 11:00 A.M. to 5:00 P.M. in five areas of the Museum: the Auditorium, the People Center, Gallery 77, the Education Hall, and the Hall of Mexico and Central America. Admission to all programs is free.

A new film about Margaret Mead herself opens the Festival at 11:00 A.M. on Saturday, October 17, in the Auditorium. *Margaret Mead: Taking Note* was produced for the television series "Odyssey," and focuses on various aspects of her life—her personality, anthropological work, and social activism. She is shown in the field, at the American Museum, and at a national women's convention. There are excerpts from her own films and interviews with people who knew her well—her daughter, her first husband, and some of her colleagues.

Films screened in the Auditorium on Saturday focus on "Disappearing Ways of Life." One of these films documents one year in the life of *The Shepherds of Berneray*, a tiny island in the Outer Hebrides of Scotland. The island's young people are abandoning their rugged existence as shepherds and fisher-

From the Stilt Dancers of Long Bow Village, *by Richard Gordon and Carma Hint*

men for a different kind of future on the mainland, and in time, Berneray will be deserted, and its Gaelic culture, now kept alive only by the old people, will disappear.

Sunday at 11:00 A.M. in the Auditorium, David and Judith MacDougall's film, *A Wife Among Wives*, will be premièred. The third and final part of their acclaimed trilogy on the Turkana, a seminomadic herding people in northwestern Kenya, this film is a sensitive portrayal of the Turkana women's view of polygamous marriage.

Sunday afternoon four films on "Black Heritage" will be shown in the Auditorium, including *Tapdancin'*, a beautifully photographed documentary about tap-dancing in America. This film traces the history of the art, paying

particular attention to the problems faced by black performers. It includes interviews with tap-dancers, a tour of a modern studio, and segments of virtuoso performances, some from early films.

Programs in the People Center will be about "Polar Peoples" on Saturday and "Archeology" on Sunday. Gallery 77 features "Portraits" on Saturday and films about "Social Issues" on Sunday. Films in the Education Hall will focus on "Spiritual Worlds" on Saturday, and "China" on Sunday. *The Living Maya*, in four one-hour segments, will be shown both days in the Hall of Mexico and Central America. Made by anthropologist Hubert Smith, *The Living Maya* is the Festival's only video production.

Margaret Mead was an educator and a humanist as well as a scientist. She felt strongly that anthropology, the study of humankind, should be understood by all people, not just by professionals; that people should learn about other ways of life so they could better comprehend their own; and that vanishing cultures should be recorded on film. Although she was a skillful and prolific writer, she thought that some of the best anthropological studies had been made with the camera and that film was perhaps the most direct and effective way to portray a people. In 1977, two years before her death, she fulfilled a long-standing wish by establishing the first Margaret Mead Film Festival. Now the Museum is continuing this tradition.

For more information and a complete schedule of the 1981 Margaret Mead Film Festival, write to the Department of Education, American Museum of Natural History, Central Park West at 79th Street, New York, NY 10024 or call (212) 873-1070.

Douglas J. Preston

Art of the Rain Forest

A major exhibition, *African Arts of the Suriname Rain Forest*, will open on Wednesday, October 28, in Gallery 3. Made up of 359 objects from the daily life of the Maroons, the exhibition shows how artistic expression is one of the fundamental elements of what has been called the most African of all Afro-American cultures.

The ancestors of the present-day Maroons were African plantation slaves who, during the late seventeenth and eighteenth centuries, escaped into remote regions of northeastern South America and established independent societies that are still flourishing today.

Maroon art has been previously thought by scholars to consist almost exclusively of woodcarving, and this exhibition will introduce for the first time a number of arts virtually unknown outside of Maroon villages, including textiles, basketry, jewelry, and a large number of calabash bowls. The exhibition will be open through January 24, 1982.

Seventeenth-Century Suriname Insects

An unusual exhibit in the Library Gallery is devoted to the work of Maria Sibylla Merian (1647-1717). In the late 1600s, Merian, the daughter of a Swiss engraver, gave up her life in Europe and voyaged to Suriname, where she painted watercolors of insects and flora. On display will be seventeenth- and eighteenth-century folios with hand-colored engravings of her work and fine reproductions of her watercolors, many of which were bought by Catherine the Great of Russia and remain in that country. The exhibit will open October 1.

Fall Lecture Series

Museum scientists and other well-known authorities will give courses in a variety of subjects including anthropology, archeology, art, and the natural sciences. Each course consists of three to eight programs of lectures, films, slides, or laboratory instruction. This is a fine opportunity for adults of an inquiring turn of mind to learn more about any of the seventeen topics offered, including Asian dancing, Tibetan culture, American archeology, and alternatives to sociobiology. The lecture series opens the third week in October, and prices range from $20 to $85. Contact the Department of Education at (212) 873-7507 for details and registration materials.

The Politics of Creation

Fundamental creationism, thought to have become obsolete with the Scopes "monkey trial," seems to have had a resurgence. Quotes by eminent scientists and scientific theories have been misconstrued to support the position of the group known as scientific creationists.

On Wednesday, October 28, at 7:30 P.M., noted scientist and *Natural History* columnist Stephen Jay Gould will present a slide-illustrated lecture exploring the current theories of evolution within the scientific community. He will then focus on how the creationists are distorting scientific principles to achieve their own ends.

Tickets for the lecture will be $2.00 for members, $4.00 for nonmembers. For ticket availability please call (212) 873-1327.

The Parade of Life

David Attenborough, who has recently completed the filming of a thirteen-part series "Life on Earth" (to be shown early next year on PBS) will present a special preview at the Museum on Sunday, October 25, at noon and 3:00 P.M. Using excerpts from the series, he will tell of his adventures during the filming in such places as the Comoro Islands, the Galápagos, and the Great Barrier Reef. The series traces the evolution of life from the first one-celled inhabitants of the primordial oceans through the more complex forms to *Homo sapiens*. The lecture will be free for members and $2.00 for nonmembers. For ticket availability please call (212) 873-1327.

Workshops for Young People

The Department of Education is offering five stimulating weekend courses for children this fall: "Photographing New York," "Exploring with the Microscope," "The World of Dinosaurs," "Reptiles and Amphibians," and "Human Origins." All will be taught by recognized scientists and educators and are specially geared for children of grades 4 through 7. The workshops start the weekend of October 24; tuition is from $14 to $20. Call the Department of Education at (212) 873-7507 for more information.

Planetarium Sky Shows

"Night of the Hunter," an exploration of the constellation Orion, will be shown through November 23. "Stars of the Season," an introduction to astronomy and the fall sky, will be shown Wednesdays at 7:30 P.M., and, beginning October 3, Saturdays at 11:00 A.M. The show covers several exciting topics, including the changing seasons, meteors, and the constellations and bright planets that will be visible this autumn. For schedules and prices, call the Hayden Planetarium at (212) 873-8828.

Laserium

The Hayden Planetarium will be featuring two Laserium programs: "Light Years," which combines laser art with songs from twenty-five years of rock-and-roll, and "Rock Alive," which uses the music of seventeen modern groups, including Led Zeppelin, Deep Purple, and Yes. The Laserium shows will run on Wednesday, Friday, Saturday, and Sunday evenings. Call the Planetarium at (212) 724-8700 for more information and admission prices.

Guided Tours

The Museum offers free tours, led by Museum volunteers, to give visitors an inside glimpse of the history of the Museum and to provide an introduction to its vast collections. Visitors may join the "Museum Highlights Tour" at the second floor Information Desk. Inquire at the desk on the day of your visit for specific times.

Give a GIFT of NATURAL HISTORY

Give one at $15 and save 20% on subsequent gifts at $12 each

AMERICAN MUSEUM OF NATURAL HISTORY
Vacations on sea and land with Museum Lecturers

NILE CRUISE: Explore the astounding ancient sites and natural wonders of Egypt with a Museum geologist, ornithologist illustrator, and Egyptologist. Cruise 600 miles on the Nile from Cairo to Assuan aboard the custom-built, air-conditioned *Nile Star* stopping at all the important sites which have intrigued visitors since their construction.

INDONESIAN ODYSSEY: Cruise through the paradise islands of Bali, Java, Komodo, Sulawesi, Lombok, Flores, Butung, the Moluccas and Luciparas aboard the luxury vessel, *Regina Maris*. Share with a Museum astronomer, anthropologist, ornithologist, geologist/volcanologist, and herpetologist a unique, in-depth travel experience. The itinerary takes you to lush tropical landscapes with exotic peoples influenced for centuries by India, Islam and Europe.

GALAPAGOS ISLANDS CRUISE: Discover a special natural world with fantastically tame and exotic animals such as sea lions, giant tortoises, marine and land iguanas and countless rare and beautiful birds. Enjoy the expertise of a Museum ornithologist and herpetologist and four local naturalists as we cruise through this equatorial archipelago which so influenced Darwin.

ADRIATIC AND AEGEAN ADVENTURE: Relive the great historical travels of the Greeks, Romans, Phoenicians and Venetians. Follow their paths on a classical cruise starting in Venice and going to Dubrovnik, Corfu, Corinth, Crete, Rhodes, Tunis, Carthage, Malta, Sicily, Pompeii, Herculaneum and Naples. The *Orpheus* will be your home for 14 beautiful days; the Museum faculty will be outstanding.

LAND PROGRAMS: Seven outstanding overland itineraries have been custom-designed for small groups of 15-25 participants. Famous and remote sites and cultures are discovered while staying at the finest accommodations available with expert Museum Lecturers.

DESTINATION	1982 Dates
☐ Archeology Tour to Mexico	January 11 to 29

Write: Adirondack Ski Tours, McMaster Rd., Saranac Lake, NY 12983. Or call: (212) 546-9202

An Art Book That Took Centuries To Create

It took the American Museum of Natural History four years to arrange its exceptional exhibition of more than 500 pieces of ancient gold from Colombia. But those few years are a brief time when compared with the decades archeologists have spent digging (literally!) and studying the gold artifacts from tombs, caves, and buried sites. And all that time is short when compared with the many centuries prehistoric Indians practiced their craftsmanship and artistry to create these treasures.

So when it became the United States sponsor for this outstanding collection, the American Museum faced a dilemma. Could we do justice to all this effort and scholarship and beauty? We think we have. First, by dramatically displaying *Gold of El Dorado: The Heritage of Colombia* in one of our largest halls. The glowing reports from visitors tell us our efforts have been worthwhile. If you don't have a chance to see the show for yourself in New York, we hope you will see it in Chicago, San Francisco, or New Orleans on its year and a half tour.

The second challenge for the American Museum was the creation of an appropriate book to accompany the exhibition. We decided against a traditional catalog; against a small, boring volume with tiny black-and-white pictures that could never do justice to these fine objects. Instead, we decided to present a select number of the finest pieces of pre-Columbian gold in a large, stunning format. And to represent the three important elements that make a great art book we chose outstanding professionals.

First, photographer Lee Boltin. One of the greatest photographers of art objects, he also took the famous pictures of the Tutankhamun show. We sent him abroad to find and record great pieces of pre-Columbian art.

Second, archeologist Warwick Bray, from the University of London. One of the world's foremost authorities on pre-Columbian art, Bray is also a skilled writer, able to present fascinating background in a succinct, readable essay in the book. Dr. Bray organized the Colombian gold exhibition in London.

Third, Harry N. Abrams, Inc., America's leading publisher of fine art books. In a co-publishing venture with the American Museum, Abrams designed the book, supervised the preparation of 30 large color plates, and monitored the fine-quality printing.

The result is an unprecedented exhibition book. It is bold and big—each plate is 16 by 11½ inches—bigger than this magazine *opened up*. The paper is heavier than most posters. In fact, many persons have purchased two copies of the book in order to have one set of these fine art prints for framing.

And now for the happy ending. Because the Museum is a co-publisher, we are able to offer this soft-bound art book at a major savings from its normal retail price of $12.50. We are pleased to offer *Gold of El Dorado* to subscribers for only $6.25—a 50% savings off its regular price. This special offer is valid only during the exhibition and only while our limited supply lasts. We suggest that you order one or more copies immediately. Of course, if you are not satisfied after you have had an opportunity to examine it in your home, simply return the book and the Museum will refund the purchase price.

Sunbelt Cuisine

Southern cooking is this country's major surviving native cuisine

by Raymond Sokolov

Millions of practical, footloose Americans have solved the problem of keeping warm in an era of zooming fuel costs by taking the path of least resistance. They have headed south where, much of the time, naturally available solar energy warms their bones and heats their homes at no cost at all. This migration has enormously distorted American life, undermining the political strength of the depleted Northeast, straining the water resources of the Southwest, and generally shaking up established patterns everywhere. One harmless benefit the "new carpetbaggers" have acquired in their flight from chill is daily access to Sunbelt food, that amalgam of traditional Deep South and western cooking that is this country's major (and perhaps only) surviving native cuisine.

For the past two years, I have been poking about all over the United States searching for healthy vestiges of regional cooking and regional foods. Almost everywhere I have gone, the dishes and ingredients touted with pride in cookbooks or at chamber of commerce events have all but vanished from the normal life of the area or are seriously threatened by industrially produced foods from other places. Agribusiness and the homogenization of modern life have turned people everywhere away from pristine clambakes, wild persimmons, and other once-rife local delicacies and on to the foreshortened national menu of hamburgers and other fast foods. But in the Sunbelt states, they order things better.

Southern-fried chicken and barbecue are in no sense vanishing foods. Indeed, as everyone knows, they have spread to the four corners of America. The mystique of good ol' boy chow has captivated folks in Boston and San Francisco. As early as 1972, fast chicken emporiums had reached Manhattan and soul food was available in many white neighborhoods. This trend has not slowed in the ensuing decade. First Kentucky, then Kansas fried chicken appeared around New York City. (More recently, perhaps as a kind of chauvinist backlash, someone opened a "New York" fried chicken restaurant.) And within the last year, fast chicken purists in the Big Apple finally got a chance to sample the southland's spiciest, crispest mass-produced fried chicken when Popeye's came to town.

With such authentic Sunbelt fare now available in my own city, you might think I would not bother to travel to Atlanta for southern cooking. Even without Popeye's practically in my backyard, I could easily have satisfied my craving for finger-licking fare by cooking one of the many outstanding fried chicken recipes I have managed to salt away (see below). As it happens, I went to Atlanta last May to meet with publishing friends at the American Booksellers Association's annual convention and, well aware of the wave of murders terrorizing the city, I resolved to take my meals in my hotel.

One look at the dismal dining room there, however, and old reflexes asserted themselves. I took to the street in search of an authentic southern breakfast and found it at a large, peaceful downtown cafeteria.

What drew me inside the S & W, a branch of a chain that extends throughout the Southeast, was a perplexing item on the menu in the window: "battered country bacon, 45 cents." This was a regional specialty I had never heard of. Did they beat crisp bacon until it shattered? It might be interesting.

At the service counter, I was handed a plate with a long, brittle, dark brown strip on it. Suddenly I realized what it was: southern-fried bacon. To the blinkered northern sensibility, this will sound like the ultimate redneck abomination. Batter-fried bacon. Refried fat.

On the palate, however, this down home specialty had its points. The bacon itself was thick-sliced slab bacon, tasty as always. And the crisp coating, which did shatter when cut, complemented the fattiness of the bacon in much the same way that toast goes with bacon in a bacon, lettuce, and tomato sandwich.

Munching on my battered bacon, I sank into speculation on the southern mania for southern frying almost everything. At its best, this method "surprises" the flavor of food and seals it in, while leaving the chicken or catfish moist and fresh inside. Southern cooks, building on these basic recipes, have extended the frying of breaded foods—from hush puppies to crab cakes to fried oysters to southern-fried partridge and quail—further than cooks of any other area.

Perhaps the most extreme form of this propensity is chicken-fried steak, not everybody's idea of refined food, but I did meet a Texan book salesman in Atlanta who visibly salivated at the mention of the dish.

For the restaurateur, deep-frying is an ideal method. Once the fat has been heated to the appropriate temperature, it can be reused several times (obviously this can be overdone and often is). The

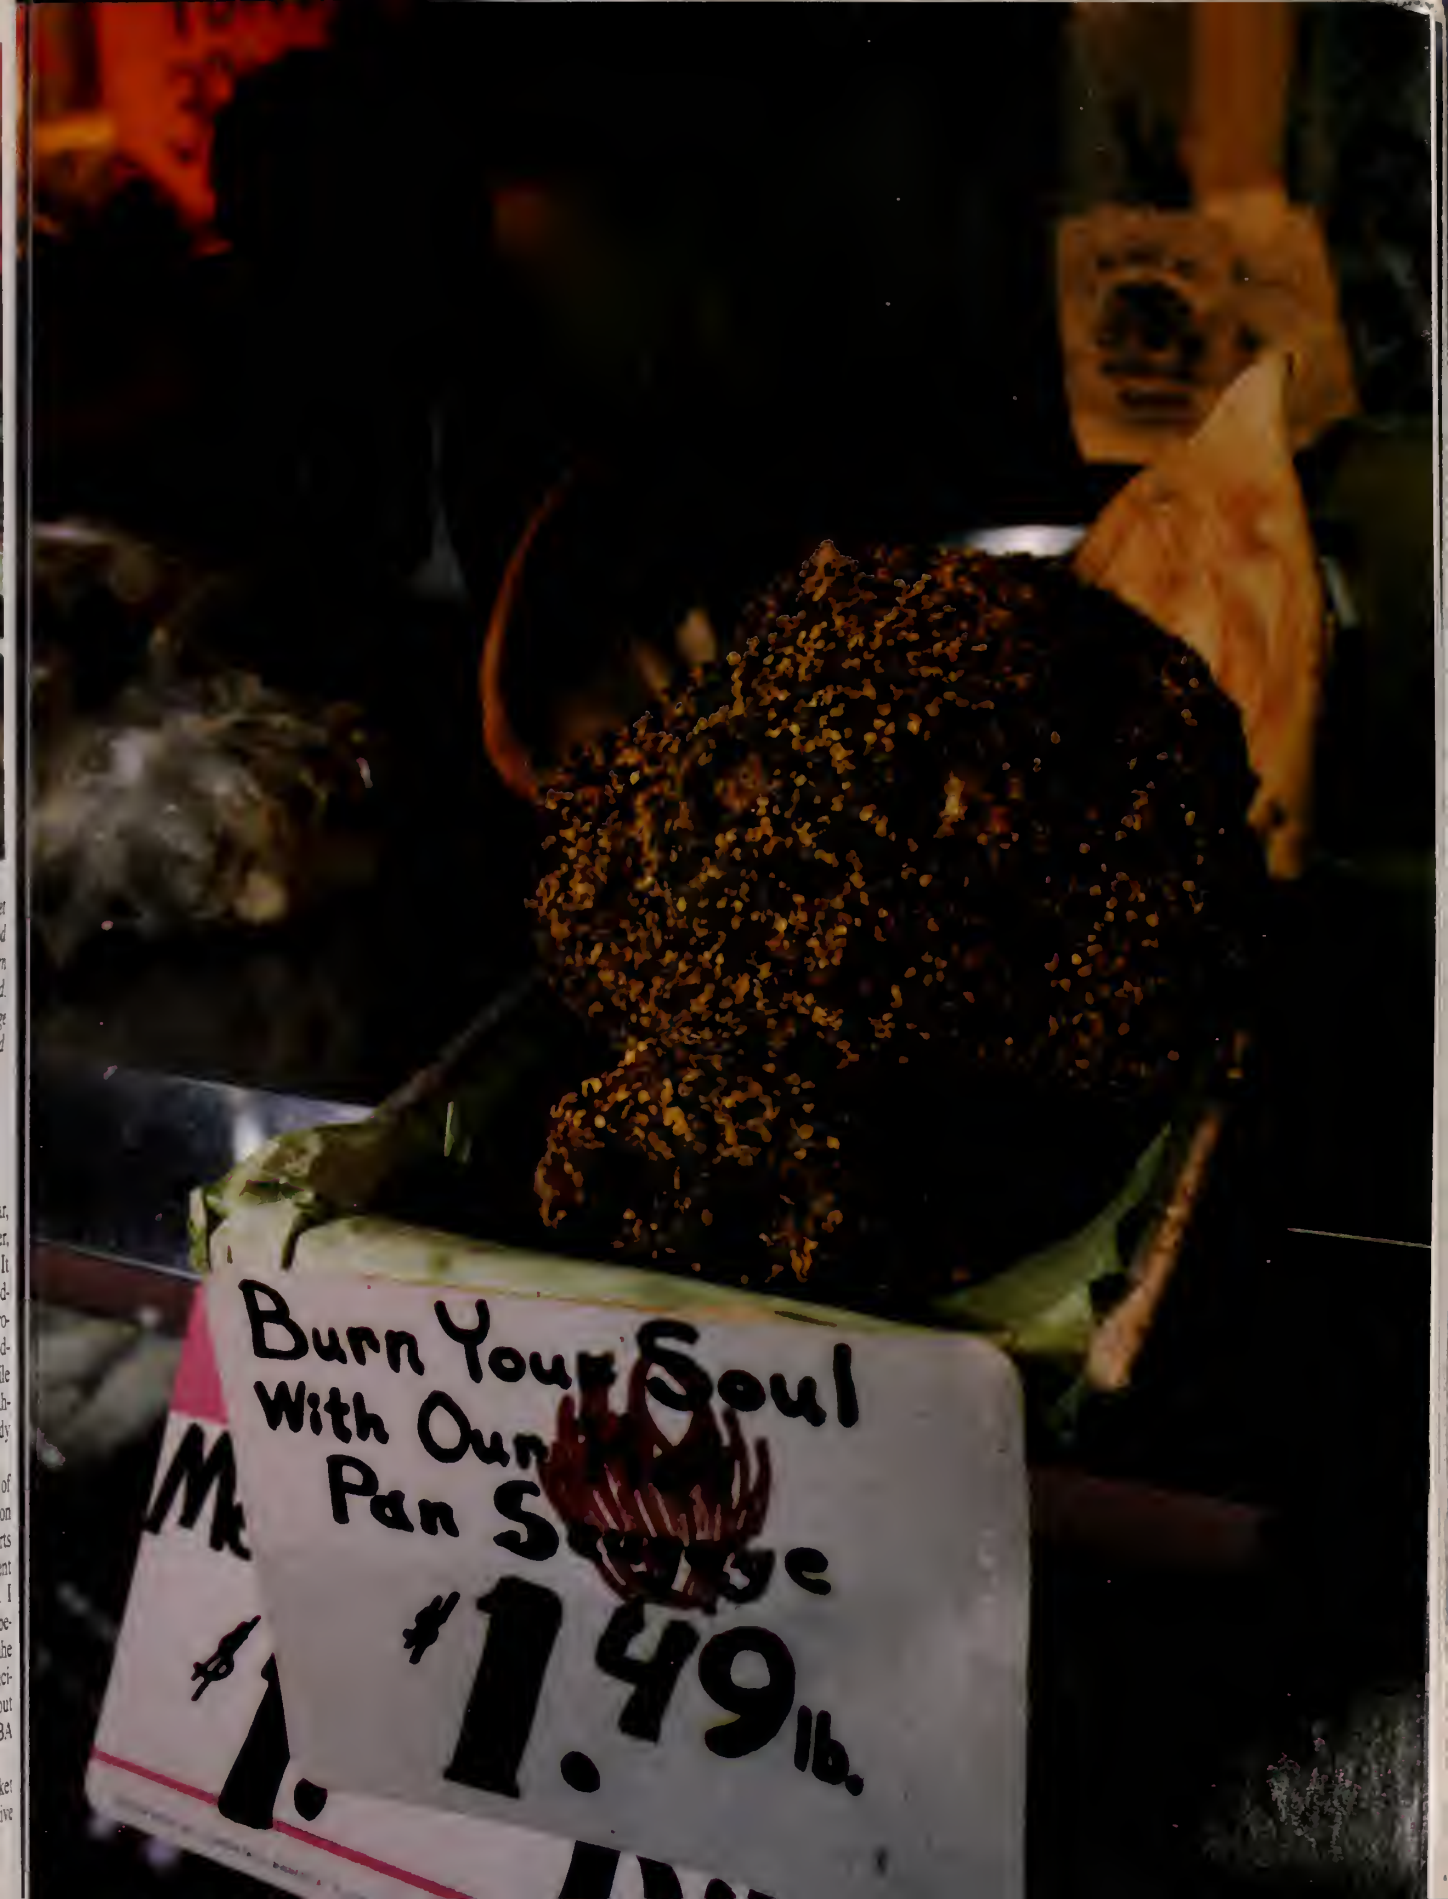
Atlanta's famous Municipal Market features row upon row of food stands. Pork, the southern favorite, is prominently displayed. At right is a mound of pork sausage in the shape of a hog's head.

process is quick and ideally suited to modern fast-food situations. You can, moreover, deep-fry almost anything. A friend of mine ran a fryolator at a chicken joint in the Southwest during a high school summer vacation. To relieve the boredom of the job, he took to methodically southern frying old sneakers. They came out golden brown, looking like giant fritters.

Southern cookery, of course, includes much more than just southern-fried foods. Among the ingredients ineradicably associated with Sunbelt eating are a huge menu of cornmeal recipes, from spoon bread to corn bread to corn pones to hush puppies. Corn also figures in the most folkloric and primordial Sunbelt recipe of all: grits.

Grits are actually hominy—corn leached out of the kernel with a lye solution. The Indians did the same thing with ashes and water. The resultant hominy, when boiled, turns into the white, porridgy starch always present at real Sunbelt breakfasts. Almost every northerner I know turns his nose up at grits. I think the name has a lot to do with it. If, for instance, the same cornmeal mush were served under its Italian title, polenta, it would sit better than it does as plain old grits.



The best grits I ever ate were the baked cheese grits served at a fund-raising event in Lexington, Kentucky, during Derby week (see recipe). Cheese grits are meant as a side dish to go with a meat meal, much as a baked potato might. Served this way, cheese grits are a most refined dish, and you can delight and mystify your friends by including them in an otherwise conventional dinner. Only Sunbelt exiles will be able to identify the dish without prompting.

In addition to pan-southern dishes such as grits, every southern subregion has its own local specialties. Southwestern Louisiana flaunts its crayfish. The town of Vidalia in south Georgia boasts of an extraordinarily mild and sweet yellow onion, officially called the F-1 Yellow Hybrid Granex, but known to serious Georgia cooks as the Vidalia. It is a prized and relatively scarce item in Atlanta. The season runs from mid-May through June. And Georgia gourmets have to check and double check that they are getting the real thing.

For the most part, however, Atlanta cooks operate in the same general culinary atmosphere inherited by other Sunbelt cooks, whether white or black, rich or poor. Details vary, local ingredients differ, but the mixture of fried food, corn products, and West African influence from slave days are all persistent and universal earmarks of Sunbelt cuisine. This unity has obvious historical roots. The South remained an insular, true region much longer than other, more prosperous parts of the country. It had its antebellum tradition as a standard of the good life and it had, gastronomically speaking, an unabashed fondness for a bountiful, cheap, and versatile ingredient that predominates in southern cooking more than all those already named. I refer, of course, to pork.

Pork is the central, basic meat of Sunbelt cookery. From battered bacon to country ham, the hog's various parts are the cuts of historical and current choice below the Mason-Dixon line. I had this impressed on me as never before when I broke away briefly from the ABA to visit Atlanta's fabulous Municipal Market situated a short drive, but worlds away in spirit, from the ABA convention.

In this old-fashioned covered market with its row after row of competitive

Burn Your Soul
With Our
Pan
#1.49 lb.

retail stands, *Sus scrofa* is king. Strolling about, I noticed whole hogs' heads, Georgia hams on hooks, piles of snowy fatback, pigs' tails in heaps, pork chitlins "loose or frozen," hog maws (three pounds for $1.25), pigs' ears and snouts, and an immense mound of pork sausage meat sculpted in the shape of a hog's head. From the ceiling flew a banner urging customers to order fresh whole pigs for July 4.

Faced with such unwonted porcine bounty, I knew that I had come into contact with a vibrant node of local culture. Outside were the skyscrapers of renovated Atlanta, a Manhattanized transplant of northern ways and means, capital of the New South. But in the Municipal Market, an older, possibly shabbier, but far less sterile and deracinated South was profusely on view.

Pork was only the beginning of the riches for sale under that roof. The dazzled shopper could snap up little packets of twigs called yellowroot and steep them for tea. There were tart little red Georgia plums and Crowder peas, double-yolk eggs by the dozen, sassafras honey, greens of several sorts in huge bunches, rabbits, and Rocky Mountain oysters.

A market, by its very existence, presupposes cooks. The Atlanta Municipal Market implies an entire population of families who thrive on a group of foods virtually unknown to shoppers in most northern American supermarkets. Perhaps I was romanticizing what those people do with their hog maws and snouts, but I was seized with a great appetite for dinner at one of their homes.

It was not to be. I ate only in well-known restaurants in Atlanta and never saw a solitary chitlin. Sunbelt food is not fancy food, and it has not turned up on menus in polite places. This does not mean that polite Atlantans turn up their noses at it. Indeed, one of the keys to the survival of this cuisine on its home ground is its continuing appeal to all classes of people, race notwithstanding. At a tony barbecue staged in a leafy suburban backyard for ABA visitors and local friends, the main course was a whole hog cooked on the grill. By the time I arrived, only a charred trotter was left, but I was mollified and uplifted when an Atlantan guest told me where to go later in the year to try opossum.

Raymond Sokolov, a writer with an interest in the history and preparation of food, is editor of Book Digest.

Two recipes from *Four Great Southern Cooks* (available from DuBose Publishing, P.O. Box 924, Atlanta, Georgia 30301, $8.95 postpaid)

Beatrice Mize's Southern-fried Chicken

1 chicken, cut up
Salt
Freshly ground black pepper
1 egg, beaten
Flour
Vegetable shortening for frying

1. Wash the chicken pieces and pat thoroughly dry with paper towels or a clean dishcloth. Sprinkle well with salt and add freshly ground pepper to taste.
2. Beat the egg and thin with a little water. Dip the chicken pieces in the egg mixture, then dredge in the flour. Set the pieces aside on waxed paper.
3. Melt the vegetable shortening over medium high heat in a deep cast-iron skillet. There should be about one-half inch of oil when melted. The oil is ready when it just begins to smoke.
4. Add the chicken pieces to the oil and cook uncovered for about 12 minutes on each side, turning only once. The chicken should be a deep golden brown. Drain on paper towels, place on a platter and serve with cream gravy.

Cream Gravy

2 tablespoons melted vegetable shortening
2 tablespoons flour
1 cup milk or cream
Salt and pepper to taste

Pour off all but two tablespoons of the oil you used to fry the chicken. Add the flour and stir over medium heat with a wooden spoon, scraping the pan until the mixture is blended and beginning to brown. Add the milk or cream and stir until thickened. Add salt and pepper to taste.

Ruth Jenkins's Baked Grits With Cheese

4 cups water
2 cups grits
2 teaspoons salt
1 teaspoon paprika
Dash of Tabasco
4 eggs
1 pound sharp cheddar, grated
8 tablespoons butter

1. Preheat oven to 350 degrees.
2. Boil the water in a saucepan and stir in the grits until thoroughly mixed. Cook until thickened, stirring occasionally.
3. Add salt, paprika, and Tabasco, and remove from heat.
4. In a large mixing bowl, beat the eggs lightly. Add a small amount of hot grits to the eggs, stirring constantly so that the eggs do not cook. Gradually stir in the remaining grits.
5. Add the grated cheese and butter and mix well. Pour into a buttered 2-quart casserole and bake for 45 to 50 minutes. Serve immediately.

Yield: Six servings

FORD EXP

Brand-new two-seat, movin' to the upbeat.

An open road, front-wheel drive, four-wheel independent suspension and enough pure driving excitement for two very lucky people. You get it all in a Ford EXP.

Two front-row seats and a grand opening.

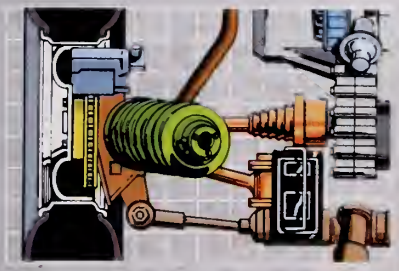
Two plus groceries, or two plus a great weekend, EXP's 29 cubic feet of cargo room can hold it all. And EXP options like flip-up open air roof can make it all the more exciting.

Just between you and EXP.

You can learn a lot behind the wheel of an EXP. Smart little gauges report on your

RPMs, oil pressure, amperes and temperature. You'll know the time. You'll even know the sports scores if you turn on the AM radio, because that's standard, too. (May be deleted for credit.) A special warning light will even tell you if your door is ajar.

Exciting numbers.



EXP's 1.6 liter CVH engine and four-speed transaxle, with fourth gear as standard overdrive, produce the kind of numbers that keep your driving fun.

46 EST HWY **29** EPA EST MPG

For comparison. Your mileage may differ depending on speed, distance and weather. Actual highway mileage will be lower.

Front-wheel drive, four-wheel independent suspension, fantastic!

EXP's front-wheel drive, four-wheel fully independent suspension and front stabilizer bar are specially tuned for sporty handling. Combine that with EXP's rack and pinion steering, standard power front

disc brakes and sport close-ratio transmission option and you'll get a whole new appreciation for the street where you live. Whether you buy or lease, see EXP at your Ford Dealer now.

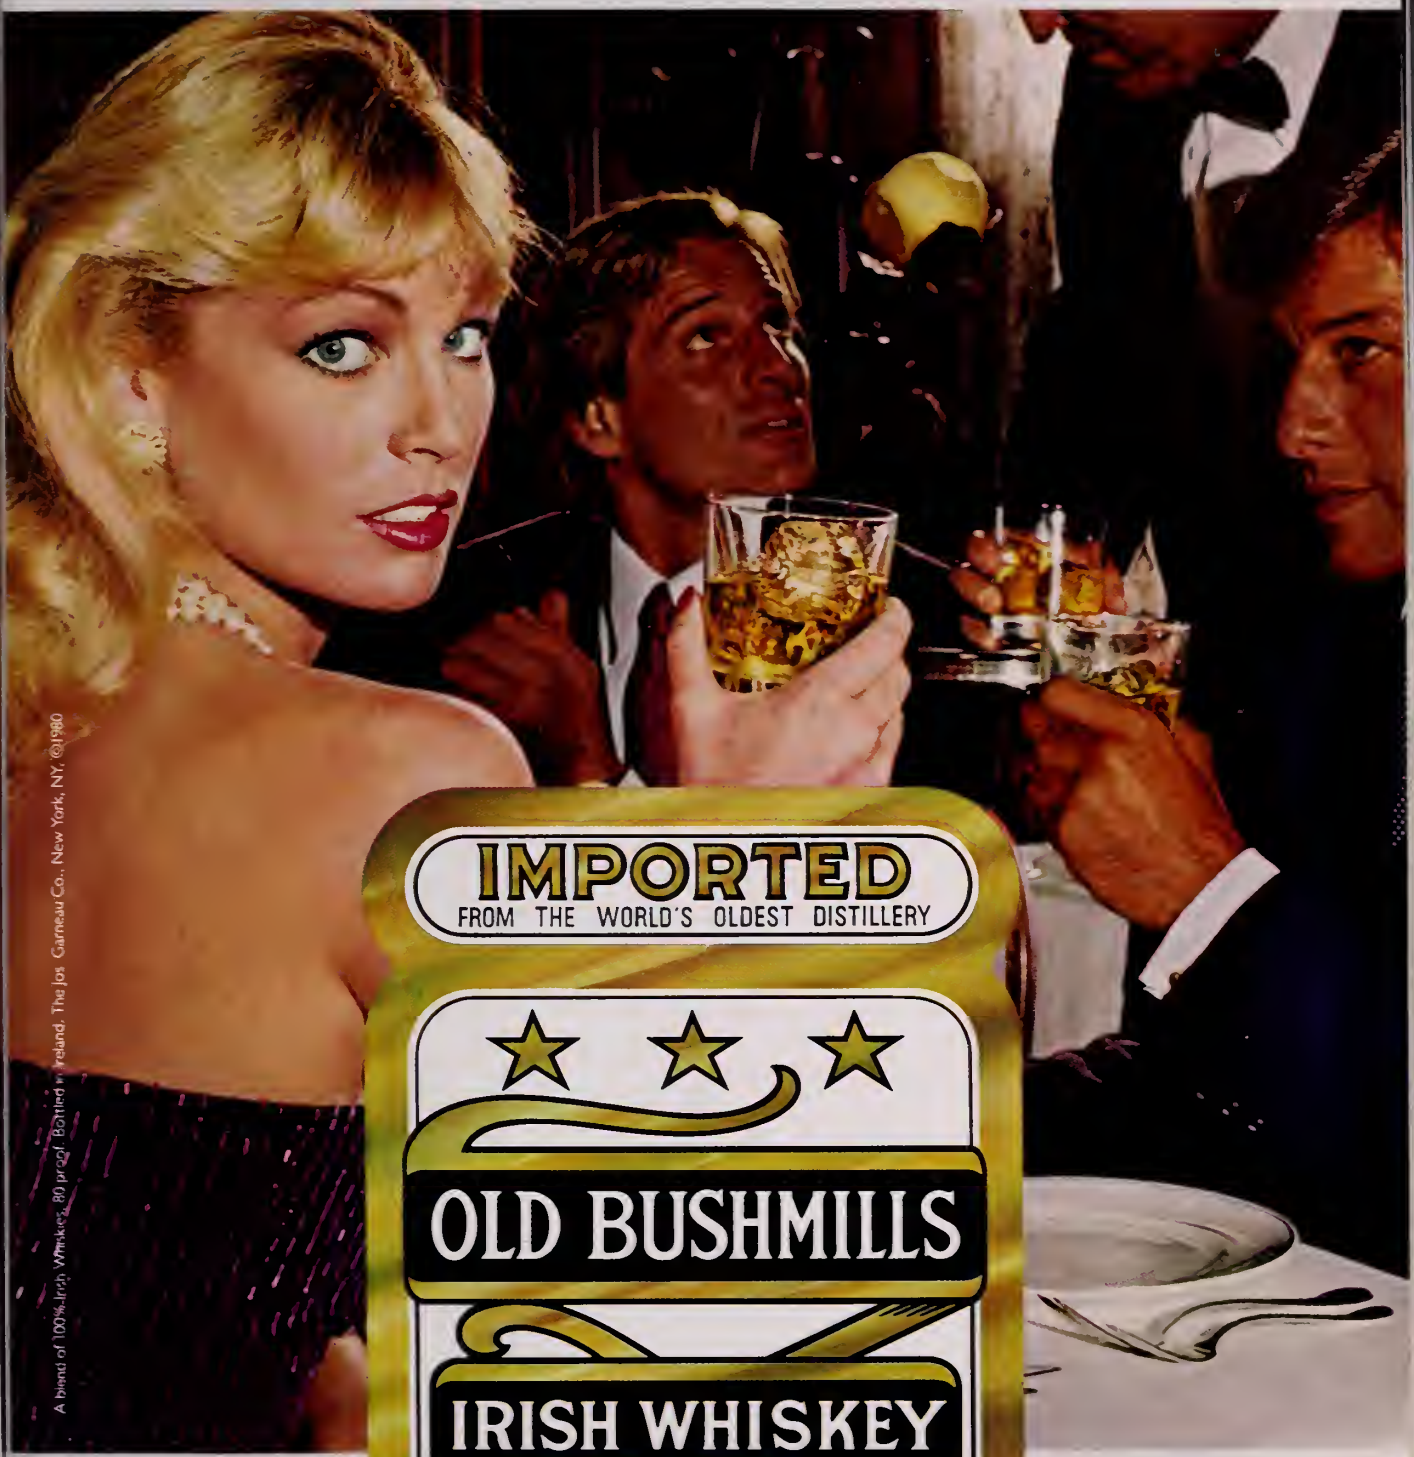
During the winter of 1972–73, when **John P. Bryant** was living in bush Alaska, he had the opportunity to observe a "particularly dramatic oscillation of the snowshoe hare population." Since that time, his research has concentrated on why hare populations do not recover as rapidly after a crash as do the severely browsed plants on which they feed. Bryant is currently a doctoral candidate at the University of Alaska in Fairbanks and a research associate at the university's Institute of Arctic Biology. When not observing hares, dog sledding, or building his log home, he enjoys traveling to more tropical climes to watch reef fish—"a nice break from the Alaskan winter."

Deep ties to the Midwest, especially Nebraska, where she was born and raised, prompted **Marilyn Coffey** to write a series of essays tracing the history of the Great Plains. These essays, including "The Dust Storms," which appeared in *Natural History*, February 1978, are to form the chapters of a forthcoming book, *American Gothic*. A graduate of the University of Nebraska with a bachelor's degree in journalism, Coffey is an assistant professor of English at Pratt Institute in Brooklyn and the recipient of the University of Nebraska's Master Alumnus Award for distinguished achievement in writing. She recently received a Master of Fine Arts degree in creative writing from Brooklyn College.



After working for twenty years in medical research laboratories, **Barbara W. Massey** entered graduate school in 1970 at California State University, Long Beach, and changed careers. Her master's thesis project was a study of the breeding biology of the California least tern. This bird, along with another endangered species—the light-footed clapper rail—has been the focus of her research during the past decade. A third pursuit, which she tries to fit into her schedule, is the study of the vocalizations and behavior of all species of the small *Sterna* terns. Massey is also a biological consultant in ornithology to the U.S. Fish and Wildlife Service, the California State Fish and Game Commission, the U.S. Bureau of Land Management, and the U.S. Army Corps of Engineers.

Physical anthropologist **Charles A. Weitz** became involved in studying people who live at high altitudes when he was invited as a graduate student to participate in a research project in Nuñoa, Peru. Having long felt an enthusiasm for south Asian cultures, Weitz later did fieldwork among the Sherpas in the Khumbu region of Nepal. His most recent research, in the Peshawar Basin of northwestern Pakistan, concerns the demographic and epidemiological changes caused by the introduction of irrigated agriculture. Weitz has been an assistant professor of anthropology at Temple University in Philadelphia since 1974.

The Ultimate Parasite

What happens to bodies if genes act for themselves?

by Stephen Jay Gould

The uncommon good prose of scientists is more often spare than flowery. In my favorite example, James D. Watson and Francis Crick used less than a page to announce their structure of DNA in 1953. They began with the sparsest announcement: "We wish to suggest a structure for the salt of deoxyribose nucleic acid (D.N.A.). This structure has novel features which are of considerable biological interest." And they ended with a reminder that they had not overlooked a major point just because they had chosen to defer its discussion: "It has not escaped our notice that the specific pairing we have postulated immediately suggests a possible copying mechanism for the genetic material" (that is, the two strands of the double helix would pull apart and each then act as a template for the reconstitution of its partner).

Francis Crick, now a professor at the Salk Institute in southern California, has continued to generate controversial, challenging hypotheses (and he has often been right). In late 1981, he will publish a book, *Life Itself*, advocating a theory of "directed panspermia"—the idea that Earth's original life arrived as microorganisms dispatched by intelligent beings who chose not to make the long journey themselves. (Ten will get you fifty that he's wrong this time—but only fifty; he's been right too often.)

Crick has also not lost his gift for a well-turned phrase. In the presentation of his latest controversial hypothesis, published a year ago in *Nature* (April 17, 1980) with Salk colleague Leslie Orgel as first author, he outdid the last line of his 1953 paper with Watson. Orgel and Crick conclude: "The main facts are, at first sight, so odd that only a somewhat unconventional idea is likely to explain them." Indeed, the facts are so interesting, and the wondering about them so intense, that the same issue of *Nature* carried an accompanying article by Dalhousie University biologists W. Ford Doolittle and Carmen Sapienza, who had, quite independently, devised the same explanation and argued the case, in many ways, more forcefully.

What, then, are these disturbing facts? When a younger Crick determined the structure of DNA in 1953, and others cracked the genetic code a few years later, everything seemed momentarily to fall into order. The old idea of genes as beads on a string (the chromosome) seemed to gain its vindication from the Watson-Crick model. Each three nucleotides in DNA codes for an amino acid (via an RNA intermediary); a string of amino acids makes a protein. Perhaps we could simply read down a chromosome to find genes lined up, one after the other, each ready to begin the assembly of its essential part.

It was not to be so. Is it ever? We now know that the genetic material of higher organisms is vastly more complex. Many genes come in pieces, separated in DNA by sequences of nucleotides that are not transcribed into RNA. Many proteins are coded by partial sequences on two or more chromosomes. What controls regulate their assembly? (Human globin, the protein component of hemoglobin, contains alpha and beta chains—and the genes for each chain are on separate chromosomes.)

Even more disturbing (and exhilarating) is the discovery, made more than a decade ago but gathering intensity ever since, that only a small percentage of DNA codes for proteins in higher organisms—and that these are the only bits of DNA whose function we may truly understand at the moment. In humans, somewhat more than 1 percent, but not as much as 2 percent, of DNA codes for proteins. Much of the rest contains sequences that are repeated over and over again—hundreds or thousands of identical (or nearly identical) beads, sometimes following one after the other, sometimes dispersed widely over several chromosomes. Why so many copies? What do they do? The "selfish DNA" hypothesis of Doolittle, Sapienza, Orgel, and Crick provides an unusual answer to the puzzling question of why so much DNA exists in repeated copies (but I will keep you in suspense for a bit and discuss the conventional answers first).

Higher organisms contain different classes of repeated DNA. One type, called highly repeated or satellite DNA, contains short and simple sequences repeated hundreds of thousands or millions of times; 5 percent or so of human DNA falls into this class. We hardly have a clue about the origin and function of satellite DNA; neither the selfish DNA hypothesis nor the conventional hypotheses can explain it. Satellite DNA is, as they say, a "whole 'nother" story waiting to be told.

The current debate over the conventional and selfish DNA hypotheses centers upon the so-called intermediate or middle-repetitive DNA, some 15 to 30 percent of both the human and the fruit fly genome. Middle-repetitive DNA exists in tens to a few hundred copies per sequence; the copies are often widely dispersed on several chromosomes.

I have said nothing, so far, about the DNA of simpler organisms—the prokaryotic bacteria and blue-green algae, which have no nucleus and carry their DNA in a single chromosome. The DNA of prokaryote (prenucleate) organisms is "better behaved" with reference to the original hopes of the Watson-Crick model. Most bacterial DNA is single copy and protein coding, almost those beads on a string after all. But even prokaryotes are not immune to repetition. A hot topic of late concerns the presence in prokaryotes of so-called transposons, transposable elements, or more colorfully, jumping genes. These sequences of DNA, as their various names proclaim, can repeat themselves and then autonomously move about to other positions on the bacterial chromosome. They often exist in about as many copies as middle-repetitive DNA in eukaryotes (higher organisms with a nucleus and paired chromosomes). This has led many biologists to propose that at least some of the middle-repetitive DNA in higher organisms amplifies itself by the same mechanism of transposition. (The selfish DNA hypothesis assumes a correspondence between pro-

(For Men, Women and Children)

Mr. Bean's favorite hunting and fishing shirt. Well made from a 7 oz. cotton flannel, thickly napped on both sides. Warm, wind resistant and comfortable to wear. Machine Wash. Six colors: Navy. Bright Red. Tan. Forest Green. Slate Blue. Ivory. Men's regular sizes: 14½ to 20. #1611W. **$17.00 ppd.** Men's long sizes: 15 to 19. #1612W. **$18.25 ppd.** Women's sizes: 6 to 20. #4311W. **$17.00 ppd.** Children's sizes: 8 to 18. #4335W. **$15.75 ppd.** (No Ivory).

Flannel Sheets

Take the chill out of getting in bed on cool evenings. Made of a tightly woven, softly napped flannelette fabric. 80% cotton, 20% polyester. Whipstitched ends. Machine Wash and Dry. Colors: White/Blue Stripes. White/Pink Stripes. White/Gold Stripes. Cut generously to allow for normal shrinkage. Three sizes: #7481W Twin (70"x 100"). **$12.00 ppd.** #7488W Double (80"x 100"). **$13.50 ppd.** #7489W Queen (90"x 104"). **$16.50 ppd.** King size available in 65% polyester, 35% cotton (102"x 102"). Solid colors: Beige. White. Sky Blue. #7464W **$18.00 ppd.**

Wood Carrier

Manufactured by us from heavy duck. Leather handles are rounded for a comfortable grip. A practical arrangement for carrying stove or fireplace wood. No dirt or bark on the floor with this convenient carrier. Size 20" x 42". #8731W. **$9.75 ppd.**

Corduroy Work Pants

Same comfortable pattern as our popular Chino Pants. Full cut, yet neat in appearance. Durable medium weight corduroy is 84% cotton and 16% polyester. Machine Washable. Two front, two rear pockets; 1¾" belt loops. "Easy alter" waistband can be expanded 1½". Even waist sizes: 30 to 44. Inseams: 29", 31" and 33". Two colors: #2815W. Navy. #2816W. Tan. An exceptional value at **$18.00 ppd.**

FREE Fall Catalog

Features practical apparel and footwear for men, women and children; hunting, hiking and winter sports equipment. Many items of our own manufacture. All fully guaranteed. Our 69th year of providing dependable outdoor sporting specialties.

karyote transposons and the source of middle-repetitive DNA in eukaryotes. Some middle-repetitive DNA probably arises in other ways, and selfish DNA will therefore not explain all of it.)

Conventional arguments for the existence of middle-repetitive DNA follow the usual Darwinian perspective. Evolution is about the struggle of individuals (bodies) to leave more surviving offspring in future generations. This struggle operates by natural selection and selection is a potent editor. Major features of organisms—and some 25 percent of the genetic material cannot be minor—must exist because they provide some advantages to individuals in the struggle for life. We must, in other words, find a function for middle-repetitive DNA in terms of advantages to the bodies that carry it.

Rumblings of claims for nonadaptive and nonfunctional status have been heard from time to time (selfish DNA is the first, and more subtle, explosion for this perspective). Still, as Doolittle and Sapienza detail in their article, the overwhelming majority of proposals have hewed to Darwinian orthodoxy: they assume that middle-repetitive DNA cannot exist in such amounts unless it confers direct adaptive benefits upon organisms. (I will save myself some words from now on by simply writing "repetitive DNA" when I mean only "middle-repetitive DNA.")

The conventional adaptationist hypotheses have fallen into two classes: one, I believe, obviously wrong on (unrecognized) principle; the other undoubtedly correct in part (I do not believe that all repetitive DNA is selfish DNA). The unreasonable arguments postulate what I like to call a "retrospective significance" for repetitive DNA—that is, they justify its existence by discussing the benefits it may confer upon distant evolutionary futures.

Suppose all working genes could only exist in one copy that coded for an essential protein. How then could substantial evolutionary change ever occur? What will supply the essential protein while evolution monkeys about with the only coding sequence that produces it? But if a gene can repeat itself, then one copy might continue to code for the essential protein, leaving the other free to change. Thus, potential flexibility for evolutionary change has often been cited as the primary significance of repetitive DNA.

I have no quarrel with the idea that redundancy may supply the flexibility that evolution requires for initiating ma-

WHY PEOPLE WHO DON'T JOIN BOOK CLUBS ARE JOINING QPB

Four reasons: Great books. Great authors. Great savings. Great editions.

QPB books are softcover editions in hardcover sizes, durably bound and printed on fine paper. But they cost up to 65% less than their hardcover counterparts.

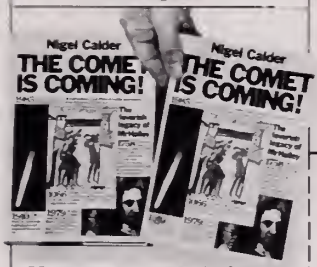
You don't judge a book by its cover, so why pay for the cover?

256

439

256. **James Beard's American Cookery.** James Beard
Hardcover: $15.95 QPB: $7.95

266. **The Moveable Nest** Tom Schneider. QPB: $7.50



386. **Rapid Viz:** A New Method for the Rapid Visualization of Ideas. Kurt Hanks and Larry Belliston
QPB: $6.50

439. **Woody Allen Set:** *Side Effects, Without Feathers, Getting Even* (3 Vols., Boxed) Woody Allen
Hardcover: $26.85 QPB Ed: $10.95

443. **On Language.** William Safire
Hardcover: $12.95 QPB Ed: $6.95

149. **Peter the Great** His Life and World. Robert K. Massie
Hardcover: $19.95 QPB: $7.95

Compare

Hardcover: $12.95 **QPB Softcover: $7.50**

257. **The Comet Is Coming!** The Feverish Legacy of Mr. Halley. Nigel Calder
Hardcover: $12.95 QPB Ed: $7.50

357. **Distant Stars** Samuel R. Delany. QPB: $6.95

449. **Movie Facts and Feats** A Guinness Record Book. Patrick Robertson
Hardcover: $17.95 QPB Ed: $9.95

458. **The Thirties:** From Notebooks and Diaries of the Period. Edmund Wilson. Edited with an Introduction by Leon Edel
Hardcover: $17.95 QPB Ed: $8.95

462. **Mathematical Magic Show and Mathematical Circus.** (2 Vols.) Martin Gardner

Hardcover: $16.95 QPB: $7.95

121. **Gödel, Escher, Bach** An Eternal Golden Braid. Douglas R. Hofstadter. QPB: $7.95

166. **Backpacking:** One Step at a Time. (Revised 1980s Edition) Harvey Manning. QPB: $3.95

384. **Oxford American Dictionary** Compiled by Eugene Ehrlich, Stuart Berg Flexner, Gorton Carruth, Joyce M. Hawkins
Hardcover: $14.95 QPB: $4.95

371. **The Concise Oxford Dictionary of Music.** (Third Edition) Michael Kennedy
Hardcover: $19.95 QPB: $8.95

405. **Let's Go:** The Budget Guide to Europe 1981-82. Edited by Jonathan Hand
QPB: $6.95

Join now. Pick any 3 books or sets for $1 each – with no obligation to buy another book.

356. **Gnomes.** Text by Wil Huygen Illustrated by Rien Poortvliet
Hardcover: $17.50 QPB: $8.50

191. **A Treasury of Modern Fantasy** Edited by Terry Carr and Martin Harry Greenberg. QPB: $7.15

571. **The Basic Book of Photography,** Revised Edition. Tom Grimm. QPB: $6.50

229. **Starting to Draw** Wendon Blake. QPB: $5.95

324. **How to Buy Money:** Investing Wisely for Maximum Return. Wayne Nelson
Hardcover: $10.95 QPB Ed: $6.95

398. **The Dinosaurs.** Illustrated by William Stout, Narrated by William Service, Edited and Produced by Byron Preiss, Introduction and Scientific Commentary by Dr. Peter Dodson, University of Pennsylvania
QPB: $10.95

635. **Drawing on the Right Side of the Brain:** A Course in Enhancing Creativity and Artistic Confidence. Betty Edwards
Hardcover: $13.95 QPB: $6.95

111. **The Search for Alexander** An Exhibition. Contributions by Nicholas Yalouris, Manolis Andronikos, and Katerina Rhomiopoulou. (Photographs)
Hardcover: $24.95 QPB: $9.95

328. **The Arbor House Treasury of Horror and the Supernatural** Compiled by Bill Pronzini, Barry N. Malzberg and Martin H. Greenberg With an introduction by Stephen King. Hardcover: $19.95 QPB: $7.15

151. **The Lord of the Rings** (3 Vols., Boxed) J.R.R. Tolkien
Hardcover: $32.95 QPB: $9.95

330. **The Poetry of Robert Frost** Edited by Edward Connery Lathem
Hardcover: $14.95 QPB: $6.95

181. **The Chinese:** Portrait of a People. John Fraser
Hardcover: $14.95 QPB Ed: $7.95

327. **Riddley Walker.** Russell Hoban
Hardcover: $12.95 QPB Ed: $6.95

284. **The Last Laugh.** S. J. Perelman
Hardcover: $12.95 QPB Ed: $6.95

381. **The New York Times Book of Wine.** Terry Robards
Hardcover: $14.95 QPB: $5.95

Let's try each other for 6 months.

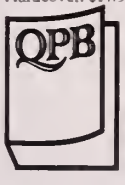
Quality Paperback Book Club, Inc., Middletown, Pa. 17057.
Please enroll me in QPB and send the 3 choices I've listed below. Bill me $3, plus shipping and handling charges. I understand that I am not required to buy another book. You will send me *QPB Review* (if my account is in good standing) for 6 months. If I have not bought and paid for at least 1 book in every six-month period, you may cancel my membership. A shipping and handling charge is added to each shipment.

QB 113-11

Indicate by number the 3 books or sets you want ☐ ☐ ☐

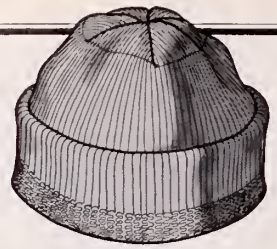
Name _____ 1-16

(Please print clearly)



Address _____ **Apt.** _____

City _____ **State** _____ **Zip** _____



How membership works.

1. You receive **QPB Review** 15 times each year (about every 3½ weeks). Each issue reviews a new **Main Selection,** plus scores of Alternates. All Main Selections with established publisher's prices are offered at *at least* 20% discount off that price.
2. If you want the **Main Selection** do nothing. It will be shipped to you automatically. If you want one or more Alternate books—or no book at all—indicate your decision on the reply form always enclosed and return it by the date specified.
3. **Bonus books for Bonus Points.** For each book or set you take (except the first 3 you get for $1 each), you earn Bonus Points which entitle you to choose any of the books we offer; you pay only shipping and handling charges.
4. **Return privilege.** If *QPB Review* is delayed and you receive the **Main Selection** without having had 10 days to notify us, you may return it for credit at our expense.
5. **Cancellations.** You may cancel membership at any time by notifying QPB. We may cancel your membership if you elect not to buy and pay for at least one book in every six-month period.

Prices generally higher in Canada.

The first book club for smart people who aren't rich.

AUTHENTIC WATCH CAP

This is the genuine article, made for us by the mill that knits them for the military. Warm and strong worsted wool is knit tight and flat to keep its shape. Wear the cuff doubled or pulled down to protect ears, neck and forehead. Rolls for stowing in gear bag or glove box. One size fits all. **Colors:** Navy Blue or Gold. **Wool Watch Cap $5.50** postpaid.

Make Spline Maple

This is not a lowly pun, but in woodworkers' parlance refers to the use of a third piece, or spline, to join two pieces of wood together. There are even blind and multiple spline joints.

Fine Woodworking magazine speaks this language to more than 200,000 readers—people seriously interested in making beautiful things out of wood. Whether you are an aspiring novice or an accomplished expert, you'll find it an especially informative magazine, with finely detailed articles about techniques and tools, materials and design. It's written by master craftsmen who share their many years of woodworking experience. And it's printed on heavy paper to withstand years of reference. All back issues are in print and indexed periodically.

If you want to become a better woodworker, send $14.00 for a one-year subscription (Visa or MasterCard accepted). Or call us toll-free, 1-800-243-7252 (in Connecticut, 1-426-8171). If you're not pleased, we'll be happy to refund.

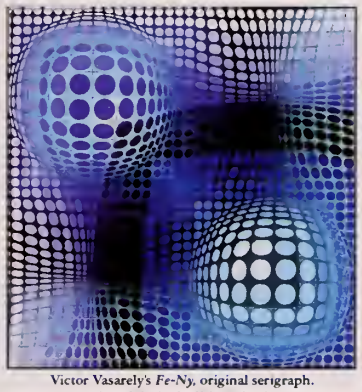
jor changes. Susumu Ohno, who first popularized this idea in 1970 in a brilliant book (*Evolution by Gene Duplication*), argued that, without redundancy "from a bacterium only numerous forms of bacteria would have emerged." Duplication supplies the raw material of major evolutionary change: "The creation of a new gene from a redundant copy of an old gene is the most important role that gene duplication played in evolution."

But think about it for a moment. The argument is sound and may represent, in fact, the major *effect* of gene duplication for evolution. Yet unless our usual ideas about causality are running in the wrong direction, this flexibility simply cannot be the adaptive explanation for why repetitive DNA exists. Selection works on individuals at the moment. It cannot sense what may be of use ten million years hence in a distant descendant. The duplicated gene may make future evolutionary change possible, but selection cannot preserve it unless it confers an "immediate significance." Future utility is an important consideration in evolution, but it cannot be the explanation for current preservation. Future utilities can only be the *fortuitous effects* of other direct reasons for immediate favor.

(The confusion of *current utility* with *reasons for past historical origin* is a logical trap that has plagued evolutionary thinking from the start. Feathers work beautifully in flight, but the ancestors of birds must have evolved them for another reason—probably for thermoregulation—since a few feathers on the arm of a small running reptile will not induce takeoff. Our brains enlarged for a set of complex reasons, but surely not so that some of us could write essays about it. Interested readers may wish to consult a technical article, to appear in *Paleobiology* during 1982, that Elisabeth Vrba and I have written about this subject. We wish to restrict the term *adaptation* only to those structures that evolved for their current utility; those useful structures that arose for other reasons or for no conventional reason at all, and were then fortuitously available for other usages, we call exaptations. New and important genes that evolved from a repeated copy of an ancestral gene can only be exaptations, and their new usage cannot be the reason for the original duplication.)

The second set of adaptive arguments is legitimate in proposing an immediate selective benefit for repeated DNA. If genes move about and insert themselves on different chromosomes, for example, they may occasionally link up with other segments of DNA to form advantageous new combinations. More importantly, much DNA, while not coding for protein itself, may play a role in regulating the DNA that does. This regulatory DNA may turn other genes on and off and may determine the sequence and location of expression for the genes that do code for proteins. If repetitive DNA performs these regulatory functions, then its dispersal throughout the genome can have profound immediate effects. Inserted into a new chromosome, it may turn adjacent genes on and off in new ways and sequences. It may, for example, bring together the products of two genes that had never been in proximity. This new combination may benefit an organism (see the classic article of Roy Britten and Eric Davidson, *Quarterly Review of Biology*, 1971, pp. 111–31).



Yet, for all these efforts, the nagging suspicion remains that these adaptive explanations cannot account for all repetitive DNA. There is simply too much of it, too randomly dispersed, too apparently nonsensical in its construction, to argue that each item perseveres because natural selection had favored it in a regulatory role. The selfish DNA hypothesis proposes a fundamentally different explanation for much of this repetition. It is radical in that literal sense of getting to the roots, for it demands that we reassess some basic and usually unquestioned assumptions of evolutionary argument—what Orgel and Crick meant when they spoke of facts "so odd that only a somewhat unconventional idea is likely to explain them."

The argument is simplicity itself once you establish the frame of mind to permit it: if repetitive DNA is transposable, then why do we need an adaptive explanation for it (in conventional terms of benefits to bodies) at all? It may simply spread of its own accord from chromosome to chromosome, making more copies of itself while other "sedentary" genes cannot. These extra copies may persist, not because they confer advantages upon bodies, but for precisely the opposite reason—because bodies do not notice them. If they have no effect upon bodies, if they are (in this sense) "junk," then what is to stop their spread? They are merely playing Darwin's game, but at the wrong level. We usually think of natural selection as a struggle among bodies to leave more surviving offspring. Here certain genes have found a way, through transposability, or "jumping,"

What your home could have in common with the Met, the Tate, and the Louvre

Claude Gaveau's *Les Mats*, original lithograph. Signed limited edition of 185.

Victor Vasarely's *Fe-Ny*, original serigraph. Signed limited edition of 250.

Ronald Christensen's *Flowerburst*, original serigraph. Signed limited edition of 295.

Franklin S. Galambos' *Soltice*, original hand colored etching. Signed limited edition of 265.

Al Hirchfeld's *Charlie Chaplin II*, original lithograph. Signed limited edition of 200.

Wilbur Streech's *Morning Light*, original serigraph. Signed limited edition of 250.

Sachiko Imai's *Femme de l'Eté*, original lithograph. Signed limited edition of 125.

In your own home, you can exhibit original work by artists who are represented in the world's great museums and galleries.

Artists like Calder. Chagall. Dali. Miró. Picasso. Vasarely.

At the Original Print Collectors Group, we offer moderately priced limited edition prints by these and other well-known artists.

Our offerings include signed original etchings, engravings, and silk-screen prints.

Each print we offer is signed and numbered by the artist. Custom-framed. Accompanied by a certificate of authenticity and a full money-back guarantee.

And each print has been chosen not only for its beauty but for its investment value.

(Works by the artists we offer tend to appreciate, sometimes as much as 30% in a single year. Perhaps that's why *The Wall Street Journal, Business Week, Money,* AP, *Barron's* and UPI have quoted us as an authority on investing in art.)

For more information, send in the coupon. There's no obligation.

You'll find out about the special pleasure of owning original art, instead of just visiting it.

Alexander Calder's *Potpourri*, original lithograph. Signed limited edition of 90.

Antonio Peticov's *Nightfall*, original serigraph. Signed limited edition of 195.

to leave more copies of themselves *within* a body. Is any other explanation required? Orgel and Crick's title reflects this reversed perspective: "Selfish DNA: The Ultimate Parasite."

I can now almost hear the disappointment and anger of some readers: "That bastard Gould. He led us along for pages, and now he gives an explanation that is no explanation at all. It just plain happens, and that's all there is to it. Is this a joke or a counsel of despair?" I beg to differ from this not entirely hypothetical adversary (a composite constructed from several real responses I have received to verbal descriptions of the selfish DNA hypothesis). The explanation seems hokey only in the context of adherence to traditional views that all important features must be adaptations and that bodies are *the* agent of Darwinian processes. The radical content of selfish DNA is not the explanation itself, but the reformulated perspective that must be assimilated before the explanation confers any satisfaction.

If bodies are the only "individuals" that count in evolution, then selfish DNA is unsatisfying because it does nothing for bodies and can only be seen as random with respect to bodies. But why should bodies occupy such a central and privileged position in evolutionary theory? To be sure, selection can only work on discrete individuals with inherited continuity from ancestor to descendant. But are bodies the only kind of legitimate individuals in biology? Might there not be a hierarchy of individuals, with legitimate categories both above and below bodies: genes below, species above. (I confess to what evolutionists call a "preadaptation" for favorable response to the selfish DNA hypothesis. I have long argued that species must be viewed as true evolutionary units and that macroevolutionary trends are often powered by a "species selection" that is analogous to, but not identical with, natural selection acting upon bodies.) Selfish DNA may do nothing for bodies, but bodies are the wrong level of analysis. From a gene's point of view, transposable elements have developed a great Darwinian innovation: they have found a way to make more surviving copies of themselves (by repetition and transposition), and this, in itself, is the evolutionary *summum bonum*. If bodies don't notice this repetition, and therefore cannot suppress it by dying or failing to reproduce, then so much the better for repeating genes.

In this sense, selfish DNA is about the worst possible name for the phenomenon, for it records the very prejudice that the new structure of explanation should be combating: the exclusive focus on bodies as evolutionary agents. When we call repetitive DNA "selfish," we imply that it is acting for itself when it should be doing something else, namely, helping bodies in their evolutionary struggle. Likewise, we should

not refer to repetitive DNA as "nonadaptive," for although it may not be helping bodies, it is acting as its own Darwinian agent. I can't think of a much better term in a language replete with anthropocentric terms, but how about "self-centered DNA"—without the opprobrious overtones that "selfish" inevitably contains.

Another argument against the use of selfish DNA lies in its historical source: Richard Dawkins's book *The Selfish Gene* (1976). Dawkins argued that bodies are the wrong level of evolutionary analysis and that all evolution is nothing but a struggle among genes. Bodies are merely temporary containers for their selfish genes. Superficially, this looks like selfish DNA writ larger, hence Orgel and Crick's decision to borrow the term. In fact, the theories of selfish genes and selfish DNA could not be more different in the structures of explanation that nurture them.

Dawkins writes as a superstrict modern Darwinian, committed to the idea that all features must be interpreted as adaptations and that all of evolution is a struggle for existence among individuals at the lowest level. He merely decided that Darwinians weren't radical enough in reducing such higher-level reveries as "the good of the species" or "the harmony of nature" to the unrestrained struggle of individuals. The struggling items are one level lower—genes rather than bodies—and the Darwinian program of reduction can go even further than modern supporters had dared to hope.

Selfish DNA, on the other hand, gains its rationale from the antireductionistic belief that evolution works on a hierarchy of legitimate levels that cannot be collapsed to the first rung of the scale. Dawkins's selfish genes increase in frequency because they have effects upon bodies, aiding them in their struggle for existence. Selfish DNA increases in frequency for precisely the opposite reason—because it initially has *no effect* on bodies and therefore is not suppressed at this legitimate higher level. Dawkins's theory is an unconventional proposal to explain ordinary adaptation of bodies. Selfish DNA survives only because it makes no difference to bodies.

The idea of selfish genes is, in my opinion, fundamentally incorrect (however stimulating) because the features of bodies that make a difference in natural selection cannot be decomposed into products of individual genes. Each gene contributes to several features and each feature is built by several genes and their complex interactions. When a body survives because natural selection has favored a set of features, selection has touched so many genes in so many complex and unbreakable connections that the idea of individual genes battling for personal survival makes no sense. (See my column of December 1977, but see especially the critique of Dawkins by evolution's grandest old man, Sewall Wright—92 and still going strong—in *Evolution*, vol. 34, 1980, pp. 825–43.) But selfish DNA can spread because it makes no features in bodies. It may be adaptive at its own level, but it is invisible and nonadaptive at the level of natural selection among bodies. Hence it may accumulate at first because natu-

ral selection cannot "see" and suppress it.

But if middle-repetitive DNA is self-centered, why does it only exist in hundreds of copies within genomes? If it can spread by transposition while other genes cannot, why does it not generate millions and billions of copies, eventually crowding everything else out? What stops it? Why is it behaving as an "intelligent" parasite (enough copies to be comfortable and powerful, but not enough to destroy the host and itself), rather than as a voracious cancer?

The potential answer to this question, proposed by both sets of authors, illustrates another interesting point about the hierarchical mode of thinking that underlies the theory of self-centered DNA. In hierarchical models, levels are not independent, walled off by impenetrable boundaries from those above and below. Levels leak and interact. Arthur Koestler, whom I do not usually praise but whose commitment to hierarchy I find admirable, chose as his metaphor for hierarchy the double-faced god Janus, standing at one level but looking for connections in both directions.

Now consider different forms of selection working at levels of gene, body, and species. A transposon enters a genetic system and begins to amplify itself by replication and movement. In the process of selection among genes, it is increasing by an analog of what we would call "differential birth" in natural selection among bodies. Its increase initially produces no interaction with the level of natural selection upon bodies, and nothing suppresses its intrinsic drive to manufacture more copies.

But eventually, if its increase continues unabated, bodies must begin to notice. There is an energetic cost attached to the replication, generation after generation, of hundreds or thousands of copies of DNA sequences that do nothing for the bodies investing that energy. Bodies may not notice a few copies, but vast numbers must eventually produce a disadvantage at the good old Darwinian level of natural selection among bodies. At this point, further increases in copies of self-centered DNA will be suppressed because bodies carrying too many copies will suffer in natural selection, taking all their copies with them when they die or fail to reproduce. The usual level of tens to hundreds of copies may well represent a balance between inexorable increase at the level of selection among genes and eventual suppression at the next level of selection among bodies. Levels are connected by complex ties of feedback. My plea for a recognition of levels other than natural selection acting upon bodies is not a negation of Darwinian theory but an attempt to enrich it.

The arguments will continue for a long time. One group of scientists notes the similarity in arrangement within chromosomes of repetitive sequences in two creatures as evolutionarily distant as the toad *Xenopus laevis* and the sea urchin *Strongylocentrotus purpuratus*. This similarity refutes self-centered DNA and points to common function, since wandering transposons, beholden only to their own level, should disperse more randomly among chromosomes. Others point out that an important transposable element in yeast and another in the fruit fly *Drosophila melanogaster* are represented in different strains of the same species by about the same number of copies, but in very different positions among chromosomes. Do the different positions represent self-centered amplification and the similarity in numbers reflect suppression at the higher level of selection upon bodies?

As with all interesting questions in natural history, the solution requires an inquiry about relative frequency, not an absolute yes or no. The logic of self-centered DNA seems sound. The question remains: how important is it? How much repetitive DNA is self-centered DNA? If the answer is "way less than one percent" because conventional selection on bodies almost always overwhelms selection among genes, then self-centered DNA is one more good and plausible idea scorned by nature. If the answer is "lots of it," then we will need a fully articulated hierarchical theory of evolution. My own inclinations are, obviously, for hierarchy. Cartesian reductionism has been the source of science's triumph for 300 years; but I suspect that we have reached its limits in several areas.

We have legitimate, idiosyncratic reasons for continuing our linguistic habit of identifying "individuals" with bodies, and for granting a primacy to bodies among the objects of nature. I can't, for example, imagine any acceptable politics that does not focus upon the primacy of individual bodies—and we weep for the inhumanity of those that did not, but flourished for a time nonetheless. Nature, however, acknowledges many kinds of individuals, both great and small.

Stephen Jay Gould teaches biology, geology, and the history of science at Harvard University.

THIS IS WHAT WE GET FOR NOT FOLLOWING THE CROWD.

A camera with a combination of features you won't find on any other 35mm SLR in its class.

A camera so extraordinary that in just a few short months it has become one of the best-selling in America.

More than a camera. An achievement. The Minolta XG-M.

What kinds of features make a camera this outstanding?

Optical precision for sharp, clear pictures.

Convenience features like automatic exposure to make taking pictures as easy as point, focus, shoot.

Important features like metered manual and exposure override that let you give full rein to your creative instincts.

Electronic features to help prevent mistakes.

Handling features like a built-in, textured grip shaped to fit the curve of your hand.

Even professional features like the optional motor drive that automatically advances the film. One frame at a time. Or at a blistering 3.5 frames per second to capture fast action. Like a touchdown pass rifling into the end zone.

And when you want to unleash your imagination, there are more than 45 Minolta computer-designed interchangeable lenses to help you do it. Along with a full system of accessories.

The Minolta XG-M is only the latest in our over 50-year tradition of creating cameras that are not simply cameras, but outstanding achievements.

See it at your Minolta dealer. To find the XG-M, just follow the crowd.

WAIT 'TIL YOU SEE HOW GOOD YOU CAN BE.

With a Little Help from My Friends

Many creatures depend on others for protection

by Milton Love

As a young boy, I was short, bookish, and wore incredibly thick glasses—attributes I enjoy to this day. Naturally, I was the prime target of every bully in the neighborhood. In desperation, I searched for a bodyguard, cultivating the friendship of a boy who was, as Arthur Conan Doyle would have remarked, "more accustomed to using his muscles than his wits." Fortunately, I never had to call upon my friend's singular talents, but many organisms regularly depend on others for protection.

Hedgehogs are Old World relatives of moles and shrews. Although fairly small animals, they are infrequently preyed upon, despite their rather charming habit of advertising their sleeping sites with assorted wheezes, snores, and gasps. Certainly one reason for their comparative immunity is their covering of stiff, springy hairs—while another is their ability to use the toxins in toad skins for their own defense.

A number of toads possess glands, lodged just below the skin surface, that secrete a variety of poisons, one of which has the ability to arrest beating hearts (including human). In spite of what might seem ample deterrent, hedgehogs often capture and eat toads with every sign of satisfaction. Before dining, the animals chew on the toad's large, poison-bearing granular glands and take the toad venom into their mouths, where contact with mucous membranes creates frothing. With their tongues, the hedgehogs slather the froth on their spines, apparently as a protective device. Occasionally hedgehogs will rub an entire toad skin over their spines.

In the laboratory, this self-anointing can be stimulated by a variety of substances, including tobacco and sour milk. The behavior seems to be specific to somewhat irritating substances, as hedgehogs eat bullfrogs and mice (which lack toxins) without such ceremony.

Internal retention of toxic substances from prey is another method of adding to one's defensive posture. Carminic acid is a potent defensive compound found in cochineals, small scale insects of the genus *Dactylopius*. Present in blood, muscles, and eggs, the bright red acid is apparently distasteful to such potential predators as ants, which give even dead cochineals wide berth. However, the caterpillar larvae of the moth *Laetilia coccidivora* circumvent and even utilize this chemical barrier. These caterpillars subsist entirely on scale insects and store cochineal remains and carminic acid in the front part of their gut. When disturbed by an ant predator, the caterpillar twists around and deftly deposits a drop of this fluid on its attacker. Moreover, the caterpillar may roll about in this extruded liquid, coating its body, a stunt that seems to deter further harassment.

Many other insects, including grasshoppers and butterflies, feed on plants containing various toxins, storing these in body tissues. For example, glycosides, the powerfully emetic compounds produced by milkweeds (family Asclepiadaceae), are ingested by the larvae and retained in the tissues of adult monarch butterflies (*Danaus plexippus*). Birds attempting to prey on glycoside-containing monarchs quickly develop a strong aversion toward their prey. However, some recent evidence indicates that not all monarchs in a population contain enough glycosides to produce an emetic response. Moreover, it appears that some birds can distinguish emetic and nonemetic individuals. On Mexican overwintering grounds, orioles and grosbeaks were observed capturing and releasing some monarchs while ingesting others. The birds were also selective as to what body parts were eaten. Abdominal and thoracic regions were favored, while wings (known to have high glycoside concentrations) were discarded. Apparently, some predators are not only able to distinguish (by taste) nontoxic monarchs but can also select the least distasteful parts of the prey.

The defensive system of the brightly colored sea slug *Flabellinopsis iodinea* is artfully appropriated from its food source, the hydroid *Eudendrium ramosum,* which possesses numerous stinging cells called nematocysts. Nematocysts contain a coiled, whiplike structure that is suffused with toxin and often lined with barbs. When the cell is triggered by mechanical or chemical stimulus, the whip lashes out, impaling the nearest tissue. Although nematocysts vary in potency, some, such as those of the Portuguese man-of-war and various Cubomedusae can kill large organisms including humans. The sea slug ingests and stores the cells in cerata—elongated tubes extending from its back.

F. iodinea feeds by grasping a hydroid in its jaws and rasping off pieces with its toothlike radula. The food material, containing nematocysts, is funneled through a buccal (mouth) cavity and esophagus lined with a tough collagen material that seems to protect the underlying tissues from any discharged nematocysts. Churning action of the sea slug's stomach separates the nematocysts' triggers from the stinging cells. From the stomach, the otherwise intact cells flow into a digestive gland that has connections to each cerata via cilia-lined canals. The nematocysts travel up these canals to cerata tips, where they are housed. The whole process, from hydroid to cerata, is rapid, taking as little as twenty minutes to complete. There are no known predators upon *F. iodinea,* for which this defensive maneuver may

Q. What is the new WEBSTER'S DELUXE UNABRIDGED DICTIONARY about?

A. It's about 2,300 pages and more than 4 inches thick!

Plus it contains these important supplements!

1. A Dictionary of Biography
2. A Dictionary of Geography
3. A Dictionary of Noted Names in Fiction, Mythology, Legend
4. A Dictionary of Foreign Words and Phrases
5. A Dictionary of Scripture Proper Names and Foreign Words
6. Abbreviations Commonly Used in Writing and Printing
7. Practical Business Mathematics
8. Forms of Address
9. Tables of Weights and Measures
10. Special Signs and Symbols
11. Presidents of the United States
12. Vice Presidents and Cabinet Officers of the United States
13. Declaration of Independence
14. Constitution of the United States
15. History of Canada
16. Charter of the United Nations
17. Air Distances between Principal Cities
18. Principal Geographic Features of the World
19. Commercial and Financial Terms

For more than 40 years Webster's Unabridged Dictionary has served as an invaluable reference for students, teachers, businessmen, secretaries ... and workers in all trades and professions. The reason is simple. Here is a dictionary that fills the need for accurate and full definitions, correct spellings and pronunciations, full etymologies, synonyms, as well as other general and specific information.

A large staff of lexicographers and linguists has painstakingly edited and updated each definition so that it is clear, accurate, and readily understood in all its senses. Many new entries have been added, including recent additions to the language in the natural and social sciences, the humanities and other specialized branches of human knowledge.

un·à bridged′, *a.* not shortened; complete; specifically, designating a dictionary that has not been abridged from a larger work.
un·ac·cent′ed, *a.* not accented; specifically, in

The large, clear, legible type shown above (actual size) "makes this unabridged dictionary the most readable one in print."

THE BARNES & NOBLE MAIL ORDER GUARANTEE

Every book you purchase from Barnes & Noble by mail must meet your standards. If not ... return it for a full refund within 30 days or credit to your charge account.

In business for 105 years, Barnes & Noble has become "the world's largest bookstore." (See the current Guinness Book of World Records.) Our goal is to sell the finest books in the world at the lowest possible prices. Ask about us at your local school or public library.

Two cool characters. $95 each.

Steuben's collection of seven Hand Coolers includes the Turtle and Frog. In smooth, polished crystal, they feel cool and soothing in the palm of your hand. Or they can control papers on your desk. 5514e Turtle: length, 2½". 5510e Frog: length, 2¼". $95 each. Signed Steuben. You may order by phone: 212-752-1441. Out of State: 800-223-1234. Or write Steuben Glass, Fifth Avenue at 56th Street, New York, N.Y. 10022. Major credit cards accepted.

STEUBEN GLASS

The Rubáiyát of Omar Khayyám

This is a complete recording, delivered by Louis Zoul, of Edward Fitzgerald's 5th version, and is the cumulative effort of three men of genius.

It is followed by a few comments and comparisons, and also Pedro Calderon de la Barca's The Dream Called Life and Life is a Dream.

Lastly, beginning with Hamlet's soliloquy, there is some of Shakespear's best.

Among the kudos we've received, this came from a professor in Ethiopia: "It is beyond compare!" A Brooklyn lady wrote: "I play it over and over. It is my treasure." While from Canada a gentleman requested: "Because the record is such a beauty, send another one."

A superlative delivery of superlative poetry

$10.00

Now there is also available a companion book. It is hand bound and printed on high bulk long life archive book paper. Estimated duration 500 yrs.

be at least partly responsible. Even *Navanax inermis,* a marine sluglike form known to prey upon many sea slug species, will actively avoid the trail laid down by *F. iodinea.*

I am the first to admit that these defending organisms (toads, cochineals, and hydroids) are less than willing participants in our little dramas. There are, however, numerous animals that assume the role of defenders of the faith with somewhat more grace.

One can, for instance, employ a bodyguard on a sort of retainer basis, as does the caterpillar larva of *Glaucopsyche lygdamus,* a small butterfly of the western United States. Incapable of mounting a credible deterrent force of its own, the tiny larva uses food to co-opt ants of the genus *Formica.* Throughout much of its life, this caterpillar is surrounded by these ants, which groom and palpate its body and feed on sugar water produced by a gland (Newcomer's organ) situated on the caterpillar's seventh abdominal segment.

The ants are the caterpillar's major protection against tachinid flies and braconid wasps, two parasitoid predators. Parasitoids are parasites as larvae but are free living as adults. The flies and wasps inject their eggs into the caterpillars, where the young grow until the caterpillars pupate, after which the parasitoids emerge, killing their temporary hosts. Ants actively attack these predatory flies and wasps, squirting an irritating liquid at them as they approach their intended victims. Removal of the ants from plants harboring caterpillars leads to a substantial reduction of the caterpillar population.

Some speculate that the ants are being shortchanged in this business arrangement, that the food value of *G. lygdamus* secretions is limited. If so, the caterpillars are no doubt mimicking the food materials of other species the ants defend, such as various plants and aphids that supply high-quality food in exchange. By capitalizing on well-established habits of these ants, the caterpillars may be receiving maximum benefits with only small expenditures. Where is Samuel Gompers when ants really need him?

Sea anemones of the genus *Calliactis* are usually found on shells occupied by hermit crabs. In at least some instances, *Calliactis* affords the crabs considerable protection from octopuses, the crabs' major predator. Octopuses prey on an unprotected hermit crab by enveloping its shell and continuously pulling on the crab until it weakens (a process that

may take days). However, the presence of *Calliactis* forms a powerful argument against such attacks. In aquarium experiments, an octopus that attacks a guarded shell will retreat very quickly, as if hurt. After a few such incidents, all attacks cease and, in fact, the octopus will retreat whenever a protected crab approaches.

The relationships between various species of *Calliactis* and hermit crabs are complex. In some cases, the anemone decides when to transfer to a hermit crab shell, moving with some alacrity from site to site. In other situations the crab has some influence, going so far as to assist in removing an anemone from one substrate and settling it on its own shell. Such is the value of an anemone that some species of hermits steal anemones from other species.

The polychaete worm *Arctonoë vittata* lives within the folds of the fleshy mantle of the marine intertidal keyhole limpet *Diodora aspera*. Though normally reclusive, the worm boarder will actively defend its mollusk host against starfish predators.

Sensing a starfish, the limpet thrashes about with considerable verve, in what is known as a mantle response. Soon thereafter—often within fifteen seconds—the worm sticks its head out from under the shell and searches about with poking movements. As it comes close to the predator, the worm's movements quicken until it touches one of the many small tube feet located on the starfish's underside. Once contact is made, the worm examines the foot with sensory palps located on each side of its head. Then it thrusts out its jaws and bites the tube foot, often repeatedly. Apparently, this is usually sufficient to cause a starfish to withdraw those feet that are in the limpet's vicinity. Scientists do not know what stimulates the worm to come to the limpet's rescue. Chemical cues emitted by host, predator, or both may be involved or the movement of the mantle may be the primary stimulus.

The world being what it is, there will be those among us who will insist on a somewhat mechanistic view of this behavior, seeing only that *A. vittata* has evolved through natural selection to defend its (limpet) territory. Ever the romantic, however, I prefer to see an embattled defender of hearth and home, where home is another organism.

Greater love hath no worm.

Milton Love is a research associate in the Department of Biology at Occidental College, Los Angeles.

Ralph Hoffmann: Unsung Guide to the Birds

Early bird guides concentrated on birds in the hand; a New England schoolmaster produced the first for birds in the bush

by Harold Swanton

Elliott Coues was not one to mince words. "The double-barrelled shotgun," he wrote in his 1874 *Manual of Field Ornithology*,

> is your main reliance. Under some circumstances you may trap or snare birds, catch them with bird-lime, or use other devices, but such cases are exceptions to the rule that you will *shoot* birds, and for this purpose no weapon compares with the one just mentioned.

His *Manual* took the student through the various disciplines to be mastered by the bird lover: choosing ammunition; cleaning and loading weapons; learning the types and traits of hunting dogs; approaching, killing, and recovering birds; killing wounded birds; handling bleeding birds, mutilations, bloodstains, decomposition, and more.

In his *Birds of the Northwest*, also published in 1874, Coues detailed an encounter with the solitary sandpiper:

> Once, coming up to a fence that went past a little pool, I saw eight tattlers of this species wading about in the shallow water, searching for food. I pulled trigger on one; the others set up a simultaneous outcry, and I expected them to fly off, but they presently quieted down and began feeding again. Without moving from my place, I fired three times more, killing a single bird at each discharge; still no effect upon the survivors. Then I climbed the fence and stood in full view of the four remaining birds; they merely flapped to the further side of the pool and stood looking at me, nodding away, as if agreed that the whole thing was very singular. I stood and deliberately loaded and fired three times more, taking one bird each time; and it was only as I was ramming another charge that the sole survivor concluded to make off.

One might wonder if this is how the solitary sandpiper got its name.

Blood lust, however, was not what sent Coues and his colleagues into the field with weapons at the ready. Great numbers of birds in the hand were required to provide the data they were compiling on size variation, molts, and feeding habits, for example. Identification alone often demanded a corpse; only in recent years have sight records been given any credence. The dim, low-power field glasses of Coues's day were simply not up to fixing on a darting warbler in a tangle of branches and determining the number of wing bars.

Ralph Hoffmann, armed and ready

SLIDE SHOW.

This Christmas get an entirely new view in slide projection. Our exclusive Slide-Scan™ built-in screen puts viewing slides right at your fingertips. Just remove the standard lens, pull out the Slide-Scan screen, and you're ready to preview, review, or just plain view your slides ... anywhere ... without putting up a projection screen!

Other new features include a conveniently located, illuminated control panel. Much longer lamp life (70 hours). And, on some models, a variable-speed auto-timer.

These new Carousel projectors make a terrific gift for anyone who has a 35 mm camera. Because they give you a more uniform corner-to-center illumination. A manual select control, which lets you remove the tray when the power is off. And a rapid, reliable, automatic focus system on the top four models.

Add all this to regular features like dependable gravity feed, an Ektanar C projection lens, and a dark-screen shutter latch. Plus accessories such as a dissolve control and a sound-slide synchronizer. Then you'll know why the new Kodak Carousel projector makes such a great gift.

***KODAK CAROUSEL*® PROJECTORS. THE NEW BREED.**

SIDE SHOW.

THIS CHRISTMAS KODAK INTRODUCES THE NEW BREED OF PROJECTORS THAT GIVES YOU BOTH.

© Eastman Kodak Company, 1981

Until the eight-power, high-illumination prism binocular became available after the turn of the century, the serious bird student had to take John Burroughs's advice: "Don't ogle it through a glass! *Shoot* it!" Amateurs and professionals alike shot birds and took them home to check tibia length and bill color, axillars, secondaries, and undertail coverts against descriptions in the works of Robert Ridgway, Thomas Nuttall, or Coues. Books of the nineteenth century document habits, mannerisms, migration dates, and particularly nests and eggs (oology was one of the passions of the day) in great detail, but field marks were mentioned sketchily if at all. There was little point in describing flight patterns and call notes when more often than not the reader would have the bird in hand. Sophisticated field identification points—nuances in color, feather edging, and subtle differences in call notes and songs that today enable a good field birder to identify confusing species—were either unknown or simply unmentioned in the literature. Although engravings would have been adequate to illustrate important field marks, color printing was nonexistent and, aside from Audubon, there were few fine bird artists until Louis Agassiz Fuertes came along toward the end of the century. For all these reasons, the idea of a field guide that would deal exclusively with sight identification developed slowly.

Forty years before Coues's *Manual* appeared, for example, Nuttall, one of the founding fathers of American ornithology, provided a description of the solitary sandpiper that is of little use to an observer in the field.

> Upper parts brownish olive, spotted and streaked with white; wings and tail dusky, outer tail feathers white with dark bars; underparts white, breast and sides with dark markings. In the winter the plumage of the upper parts is dark ash, and the markings are less distinct.

The barred outer tail feathers, an important field mark, are mentioned but not emphasized. Nuttall grouped the solitary with the green sandpiper of Europe, although they are different species distinguishable in the field; he also made no attempt to separate the solitary from such similar birds as the spotted sandpiper and the lesser yellowlegs. The engraving accompanying the essay is of little help. Following the description is a page and a half of text dealing with nest and eggs, idiosyncrasies, and feeding habits.

Frank M. Chapman's *Handbook of Birds of Eastern North America* appeared in 1895 and remained a standard reference work for three decades. Published in a pocket-size format, the book provided detailed descriptions and syllabicated call notes in some species, but it was still really more for the bird in the hand than in the bush. Chapman evidently recognized its shortcomings. In the preface to his 1903 *Color Key to North American Birds*, illustrated by Chester A. Reed, he wrote:

> To learn to call a bird by its right name is the first step in the study of ornithology. . . . From the scientific point of view there is but one satisfactory way to identify a bird. A specimen of it should be in hand . . . [but] we cannot place a gun in the hands of these thousands of bird lovers whom we are yearly developing.

In some respects, however, Chapman's laudable objective of simplifying things added to the confusion. Perching birds, for example, were grouped, not by relationship, but by color: the meadowlark is cheek by jowl with the evening grosbeak, the yellow-headed blackbird with assorted warblers. The colors superimposed on engraved sketches were not entirely successful; descriptions were short and telegraphic.

Florence Merriam Bailey's 1902 *Handbook of Birds of the Western United States* was another turn of the

IT'S A PERFECT TIME TO INVEST IN GOLD

SOLID 24KT. GOLD INGOT SWISS WATCH

Now, own pure gold and a magnificently fashionable time-piece. One you can wear with confidence, pride and pleasure. The face—an authentic 24 Kt. Solid Gold Ingot—.999 pure! Solid Gold. Solid luxury. Solid evidence of your excellent taste . . . and excellent investment wisdom. Behind that splendid Solid 24 Kt. Gold Ingot face is a masterfully crafted 17-jewel Swiss timepiece . . . with a superb jewel stem and genuine leather band. Reliable. Dependable. The precision Swiss movement leaves nothing to be desired. It's shock protected, and guaranteed for one year. Unquestionably, a watch of unique splendor. The most memorable gift you can give. What man or woman will ever forget receiving their own superlative 24 Kt. Solid Gold Ingot Swiss watch . . . a watch to cherish for a lifetime. And what about you? Wouldn't you relish seeing one gleam and glint on your own wrist?

©Columbia Minters 1981

century effort to help the novice. Following a description of each bird—including information on distribution, nests, and measurements—Bailey often gave some key field marks, although sketchily. For example, she included the important barred outer tail feathers in her list of the characters of the solitary sandpiper, but she failed to point them out where it really matters, that is, in comparisons with similar species. All she said in this regard is that "the solitary is distinguished from the other sandpipers in the field by its dark color and black wings, and by its shrill note as it takes wing."

One welcome aspect of Bailey's book is the occasional short paragraph giving additional information on habitat and behavior. Solitary sandpipers are said to be "quiet, shy birds, but not unapproachable, and they show an interested curiosity in strangers." The handbook has 33 plates by Fuertes, not specifically geared for field identification, and more than 600 cuts in the text, although many of the latter are tiny photographs of study skins, not renderings of live birds.

Two years later, with the publication of *A Guide to the Birds of New England and Eastern New York*, the first true field guide arrived. The author was Ralph Hoffmann, a young schoolmaster and Latin scholar with an eye for field marks, an ear for songs and call notes, a writer's gift for setting them down, and an amateur's joy in his task. While others had recognized the need for books addressed to the growing numbers of amateurs interested in the study of birds, Hoffmann was the first to concentrate on field identification alone. In his preface to *Birds of New England*, he took the reader by the hand:

> The study of birds presents plenty of difficulties, which add fuel to the flame of real enthusiasm; there are sloughs of despond beyond which the faint-hearted never get. A guide who knows the way, its pitfalls and short cuts, is always welcome . . . when our only weapon is the opera-glass.

The *Guide* had four black-and-white wash drawings by Fuertes and 95 cuts, generally good sketches illustrating diagnostic field marks. The text paid unprecedented attention to behavior, habitat, and above all, call notes and songs. Hoffmann seems to have been among the first to recognize that the sounds birds make are essential to the identification of many species in the field. In many cases, he syllabicated them expertly with a refined phonetic system, both here and, to an even greater extent, in his *Birds of the Pacific States*, which appeared in 1927.

One last look at the solitary sandpiper, this time through Hoffmann's eyes:

> *Ad. in spring.*—Upper parts olive-brown, sparsely speckled with white; front of neck streaked with dusky; outer *tail-feathers white, barred with black*; wing not showing a row of white spots in flight. *Ad. in fall.*—Upper parts dark ashy, even less speckled with white; front of neck less streaked with dusky. *Im.*—Upper parts brownish-gray, everywhere speckled with white; sides of head and neck dusky; rest of under parts white; tail as in adult; legs greenish.

Note his points of emphasis in the abbreviated description—the barred tail feather field mark is italicized (and illustrated in an accompanying sketch) and the unmarked wing pointed out. Furthermore, in comments following the description, Hoffmann compares the solitary sandpiper's call notes, wing markings, and flight with those of similar species, along with evidence to be gained from habitat. Everything in the profile is aimed at identification in the field. As he explained in the introduction,

> There has been no attempt to give a com-

FREE FULL COLOR CATALOG OF DISTINCTIVE BRITISH POST OFFICE PHILATELIC SPECIALTIES

Reserve now for your free copy of the new *1982 British Collection* catalog. This twelve-page, full color catalog offers a breathtaking array of First Day Covers, Postal Cards, commemoratives, definitives, and Year Pack collections. There's even a wide range of unique specialty items containing postage stamps which are not readily available.

The British Collection catalog is a visual treat, perfect to begin a collection, add to one, or as a gift selector. It's yours free when you complete and mail the coupon below.

SPECIAL OFFER

Official British Post Office Miniature Sheet Set
The 1981 Christmas Series Philatelic Pack*
*To be issued November 18, 1981

This special advance offering is to introduce you to the craftsmanship and quality of the items in *The British Collection*.

Handsome Miniature Sheet Set. Includes the already scarce 1978 "British Architecture" Sheet, and the desirable 1979 "Sir Rowland Hill" and 1980 "London '80 International Stamp Exhibition" Sheets. This set contains the *only three Miniature Sheets ever issued* by the British Post Office.

Christmas Series Philatelic Pack. Among all the holiday stamp commemoratives issued worldwide, British Christmas issues are often considered the most popular and exciting. Includes the Presentation Pack of stamps, First Day Cover and Postal Cards of what's sure to be a sought-after issue.

THE BRITISH COLLECTION
BY STANLEY GIBBONS
P.O. Box S, Carle Place, N.Y. 11514

ASIA: *Traditions and Treasures*

A Rare Offer to Members of the American Museum of Natural History

A MAGNIFICENT BOOK

For the first time, the Asian treasures in the vast collections of the American Museum of Natural History are unveiled in a majestic hard-covered volume: *Asia: Traditions and Treasures* by Walter A. Fairservis, Jr., with color photographs by Lee Boltin. Asia—the mother of civilization—has fascinated the West for centuries. For the past 112 years, the Museum has assembled the greatest collection of Asian art, archeology, and ethnology in the Western Hemisphere. Part of the collection is now on display in the stunning new Gardner D. Stout Hall of Asian Peoples at the American Museum.

ASIAN TREASURES IN FULL COLOR

The large-format book contains 96 superb full-color photographs of priceless Asian treasures: translucent jades, delicate ivories, silks and wrought brasses, worked gold and silver, richly woven rugs, statues of terrifying Buddhist demons, painted silk tapestries, and much, much more.

RARE ARCHIVAL PHOTOGRAPHS

Asia: Traditions and Treasures is enriched with more than 100 fascinating nineteenth and early twentieth century photographs from the Museum's archives, most never before published. These intimate pictures of people, street scenes, cities, and landscapes are an invaluable glimpse of traditional Asia—now lost forever.

A JOURNEY OF DISCOVERY

In evocative prose, Dr. Fairservis sweeps the reader across Asia, focusing on the masses of people and the so important land bridges between Asian countries. He weaves together the human story, from dwellers in the earliest villages of civilization to rugged Siberia nomads to powerful emperors ruling vast domains from the cente of the world. The book is a love affair between a man and a cont nent. The author longs to return to Asia, and you will, too, aft you experience *Asia: Traditions and Treasures*.

A LANDMARK PUBLICATION

Asia: Traditions and Treasures is a landmark publication of tl American Museum. It celebrates the creation of the Hall of Asi Peoples, the largest exhibition of its kind in the West. The M seum and Harry N. Abrams, Inc., publishers of fine art books, ha jointly produced the book. It has been printed and bound with ca by Asian craftsmen.

Yes, I would like to order__volume(s) of *Asia: Traditions and Treasures*. I understand that the book will be sent to me with a bill at the special discount price of $39.95 plus $2 for shipping and handling per book. If I am not satisfied, I may return my volume within ten days for a full refund or credit. This offer is valid only until December 31, 1981 and is open only to Members of the American Museum of Natural History.

☐ Bill me. ☐ Payment enclosed (in an envelope, please).

A Special Offer for Members

Asia: Traditions and Treasures will sell in fine arts bookstores for $50.00. However, the Museum is offering its Members an opportunity to purchase this book for only $39.95 until December 31, 1981. This large, 20% savings is available *only* to Members of the American Museum and *only* until December 31, 1981. So please place your order soon with the attached postage-free reply card. We will mail your volume to you for a free 10-day examination. If it does not meet your expectations, simply return it to the Museum for a full refund.

THE AUTHOR Archeologist Walter A. Fairservis, Jr., could have been a model for the hero of *Raiders of the Lost Ark*. More than three decades ago, he journeyed through Japan and dangerous areas of China as an Army intelligence officer. Since then, he has led many expeditions into remote archeological sites in Asia. He also teaches at Vassar College. Dr. Fairservis was the scientific consultant for the Museum's new Hall of Asian Peoples. The depth of his knowledge and love of Asia permeates this readable book.

THE PHOTOGRAPHER Lee Boltin is famous for such fine art photography as his pictures in the best-selling catalog and posters for the King Tut show. But few of his admirers realize that Boltin learned his craft at the American Museum of Natural History during the decade following World War II. His return to the Museum to photograph the priceless objects from the Asian collection was a labor of love, and the lovely color photographs in this book show it.

HE WAS never elected. But every night "Mayor" Orlo McBain is the last man to walk the streets of Culross, Scotland. He checks a knob, closes a gate and goes his way. The good things in life stay that way.

Preferred for smoothness, Dewar's® never varies.

Authentic.

plete description . . . nor does the book contain anything like full biographies of each species. . . . Full accounts of the lives of the birds are to be found in many excellent books . . . which may be used to supplement this Guide.

Hoffmann's recognition of the importance of field observations grew out of a boyhood of birding. Born in Stockbridge, Massachusetts, in 1870, he was such an expert birder as a boy that when the English poet Matthew Arnold came to town and wanted the best bird watcher available to take him walking in the Berkshires, the townfolk summoned thirteen-year-old Ralph.

Hoffmann graduated from Harvard at twenty, married at twenty-three, and spent most of his life as a teacher, not a scientist. Not until the last decade of his life, when he was summoned to the directorship of the Santa Barbara Museum of Natural History, did he leave schoolteaching.

He had no formal training in ornithology or botany, and although he became an expert in both fields, he retained his amateur status. As a Latin teacher, he would have been pleased to point out the root of the word *amateur—amator*, Latin for "lover." Hoffmann brought an amateur's excitement and joy to his work, reflected in every line he wrote.

He came to the classics naturally: his father, Ferdinand Hoffmann, was a distinguished Latin and Greek scholar who ran a boys' boarding school in Stockbridge. While working on *Birds of New England*, Ralph supported his wife and three children by teaching Latin at Brown and Nichols School in Cambridge. In 1909 an offer came for the headmastership of the Country Day School for Boys in Kansas City. Under his direction the school grew from a gathering of eighteen boys in an old country homestead into a preparatory school with eighty-five students.

In 1919, Hoffmann accepted a post at the Cate School for Boys in Santa Barbara. The flora and fauna of California were terra incognita and an exciting challenge. He responded by beginning, almost immediately, the research that culminated eight years later in *Birds of the Pacific States*.

His diaries chronicle progress on the project from the start on April 3, 1921—"Started notes for Cal guide"—to the finish on June 2, 1927—"G. [Gertrude, his wife] brought a copy of The Book home from town." Hoffmann comes alive in the entries between. Bird notes appear throughout: the first pileolated (Wilson's) warbler of the spring;

If you like the outdoors, you'll love canoe

Since 1973, America's only canoeing and kayaking magazine.

THINK canoeing all year long. Join us in armchair cruising, whitewater thrills, expeditions, racing, sailing and special events ...all in 6 big, colorful issues each year.

EXPLORE rivers, lakes, tidal waters with maps, pictures and detailed articles by the greatest group of writers, photographers and outdoor experts in the paddling world.

LEARN where to go for the best canoeing...where to camp, what to pack, what's new...plus how-to articles and our famous annual Canoe/Kayak Buyers Guide supplement.

Richard Leakey reveals the latest answers to our oldest questions.

Called "the organizing genius of modern paleoanthropology" by Harvard's David Pilbeam, Richard Leakey takes us across seven continents, from the fossil beds of East Africa to the caves of Peking Man, and through millions of years of human history to unearth the latest clues in the story of what made us the way we are today.

"No one is better equipped for the task. Well written and beautifully illustrated."—DESMOND MORRIS, author of *The Naked Ape*

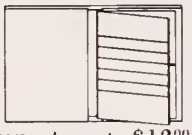
Thinner Wallets

Until recently the thinnest wallets were made from expensive seal skins. Then a new material was developed—Oxford Nylon. Pin Craft Corporation patented a unique line of wallets out of this durable woven material. Consumers' Research Magazine did an extensive study on wallets and concluded by giving their top recommendation to Oxford Nylon wallets. Oxford Nylon does not have the thickness of leather, yet it is more durable, lighter, longer wearing, flexible and very thin. Thus the Oxford Nylon wallet is more comfortable to wear, and your clothes look better without a wallet bulge.

Available in the 3 most popular styles, all have window cases for 16 or more credit cards. You can try an Oxford Nylon wallet with the understanding it can be returned within 31 days for full refund. The wallets are sold regularly (since 1973) through the Wall Street Journal. Three year guarantee. Great gifts for friends and associates. Give yourself a 10% discount when ordering 3 or more. Send the coupon or equivalent information to:

Pin Craft Corporation Dept. NH6
16 N. Mentor Ave., Pasadena, CA 91106



Sportster — Smallest and thinnest. A card-case and billfold, for hip or shirt pocket. $7.00

Classic–Thinnest hip pocket wallet with a section for money and notes plus two hidden compartments. $10.00

Executive—Coat or hip wallet with a handy stacking rack for credit cards and a 3½x5 picture window. Two hidden compartments. $12.00

condors in Sespe Gorge; nesting petrels on the Channel Islands off the Santa Barbara coast. He also reports on tennis matches (he played with John Galsworthy and beat him 6–4, 1–6, 6–4) and planting dates for vegetables, as well as some head-butting with William Leon Dawson, author of *Birds of California.* There were field trips in his open Ford to Sequoia and Yosemite national parks, to Arizona, and to the wilderness of Modoc County, where he first heard reports of the disastrous earthquake that hit Santa Barbara in 1925. Writing about one of his desert expeditions, Hoffmann noted:

> I had better luck with my car than I deserved. I camped out one night in the desert and in the morning found I had a flat tire. My spare was also soft. I took out my pump and found a nut was missing and the handle wouldn't stay on. I started to walk to the nearest station to get my pump repaired. The first car I met was run by a sewing machine agent . . . who had two hundred nuts of every size and description, one of which fitted my pump. Considering the fact that I had gone on a desert trip without looking to see that my pump was in order, we might say that there were two hundred and one nuts represented.

The appearance of *Birds of the Pacific States* in 1927 brought cheers from the birding world and huzzahs from academe. Florence Merriam Bailey put her finger on the quality that to this day remains the book's greatest strength: "Your field introductions—putting your bird in its setting, as Mr. [John] Burroughs said—are delightful, admirable, a real pleasure to an old field worker."

© 1927, 1955, Houghton Mifflin Co.

Solitary sandpiper from Hoffmann's Birds of the Pacific States

To assert as some old-time birders do that Hoffmann's *Birds of the Pacific States* is the finest American field guide ever written may be to overstate the case. What is unarguable, however, is Hoffmann's ability to forecast with near prescience the exact circumstances—region, habitat, season, feeding behavior, call notes, song, idiosyncrasies—under which birders are apt to encounter each of the subjects they profile. Always the teacher, he takes us by the hand to the edge of a marsh, to a streamside willow thicket or an alpine meadow, picks out his bird, brings it into focus, and tells us what to look and listen for. Nobody before or since has done this quite as well. In this respect, *Birds of the Pacific States* is a classic.

With the publication of his guide in 1927, Hoffmann had five years remaining to him before his tragic, but somehow fitting, death. The *Birds* behind him, he was now absorbed in botany, particularly the buckwheats. He had made frequent trips to the Channel Islands in search of them, and when the opportunity came to go to San Miguel Island on July 21, 1932, he enthusiastically took it. Arriving at the island, Hoffmann decided to collect some buckwheat specimens growing on a nearby cliff before joining his companions. He never appeared. A search was begun in heavy fog, and eight hours later, some time after nightfall, his crumpled body was found at the foot of an almost perpendicular cliff. He had evidently tried to climb after his buckwheat specimen, using his trowel for support, and the handle had snapped off. It was found beside the body.

Hoffmann is remembered today in Santa Barbara, particularly by those connected with the museum. A plaque in the Hoffmann Loggia memorializes him as "a student of flowers and birds who welcomed the children and made the museum a center of inspiration for all lovers of life and beauty."

But he is forgotten elsewhere. *Birds of the Pacific States* remained in print for fifty years but is now unavailable. As Joseph Hickey, a wildlife ecologist and longtime birder, recently observed, "In looking over Hoffmann's books, one is impressed with the fact that he must have been a terrific field man. One feels embarrassed that the obituary in *The Auk* didn't even spell his name right."

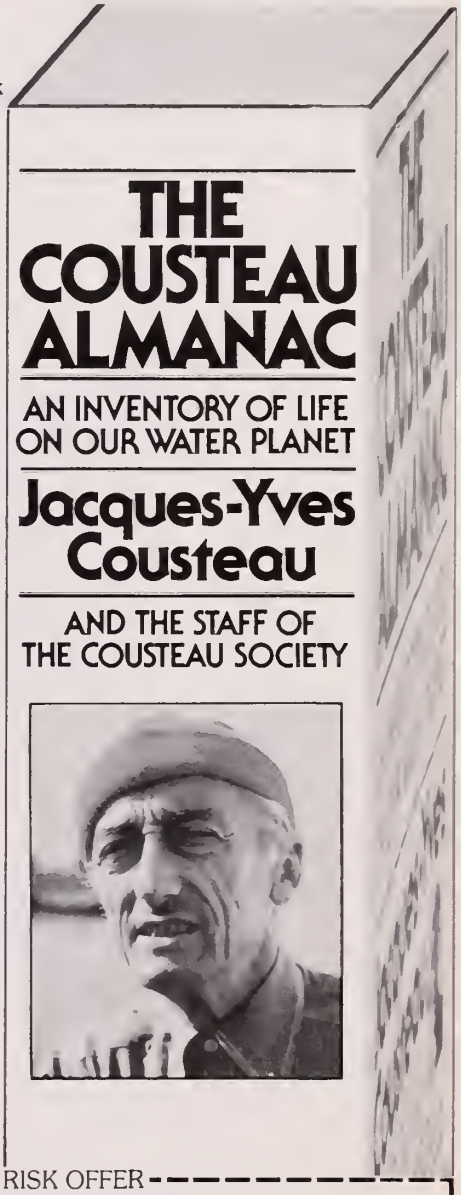
Harold Swanton, a retired writer for radio, television, and the movies, has been a bird watcher for fifty-three years.

The book for everyone who cares about planet Earth's survival

It's an almanac • statistical reference • fascinating history • blueprint for concerned citizens • atlas of natural wonders • picture book of mankind • solar energy handbook • conservation quizbook • world tour of environmental "hot spots" • ecological economics survey • a new perspective on our planet's future—and much, much more...

Jacques Cousteau and the Cousteau Society have created a unique almanac of ecological facts, figures and issues—a book that offers, in one volume, information, entertainment, and a serious call to arms for everyone who asks, "What can *I* do to help?"

864 pages long, and with over 300 photographs, illustrations and maps, in an oversized format, THE COUSTEAU ALMANAC surveys our entire living planet to reveal the often "hushed up," behind-the-scenes stories of environmental crises. But it also previews promising *solutions* to these ecological problems. And it provides a fascinating compendium of vital statistics about everything under the sun, moon, and rain. You'll discover for example:



- The biological causes of inflation
- The ironic tale of New York's almost-solar skyscraper
- The typical consumption of a United States citizen (14 pounds of cotton, 187 pounds of meat, 195 packs of cigarettes, 650 pounds of paper and 1,359 pounds of steel per year)
- The "roots" of common man-made items—including paper clips, blue jeans, gasoline, and the Big Mac hamburger
- How to build a better automobile and bicycle
- Things you didn't know you were eating
- How to engineer a famine
- How to make a cow—a recipe that starts with one 80-pound calf, requires more than two years of preparation, and could otherwise feed a thousand people
- The price of war (During World War II, it cost the U.S. an average of $225,000 to kill each enemy soldier)
- The advertisements that saved a canyon
- Animals you'll never see (plus eight endangered species that appear as official symbols of their native lands)
- Large things we've got to save—including the Amazon rain forest, whales, and the ozone layer

An unconventional almanac for uncommon times

"THE COUSTEAU ALMANAC is must reading for all those committed to the successful continuance of humankind in the Universe," writes R. Buckminster Fuller.

Publishers Weekly calls it "an extremely readable, educational book...filled with lore, history, statistics, warnings, suggestions and profiles of influential individuals. ...The contributors touch upon just about every imaginable ecological trend."

Send for your copy now. If you don't agree that this is a book you *must* have, return your copy within two weeks for a full, prompt refund.

DID YOU KNOW THAT...

... a top tourist mecca—the Caribbean—is also the most pesticide-damaged area of the world ocean?

... "acid rain," which has killed the fish in 90% of America's northeastern mountain lakes, is now quietly destroying the Acropolis and many of Europe's greatest cathedrals?

... there are more insects in one square mile of rural land than human beings on the entire earth?

See why Pete Seeger says: "It's much more than a book of dry facts. Every school in the world should have a copy!"

NO RISK OFFER

To your bookseller or
Doubleday & Company, Inc.,
Garden City, New York 11530

A Gift for Health

For Someone You Love

NordicTrack

Jarless Total Body Cardiovascular Exerciser

Duplicates X-C Skiing for the Best Motion in Fitness

Highly Effective and Pleasant To Use
The enjoyable sport of cross-country skiing is often cited as the most perfect form of C-V exercise. Its smooth, fluid, total body motion uniformly exercises more muscles and higher heart rates seem easier to attain than when jogging or cycling. NordicTrack closely simulates the same pleasant motion and provides the same cardiovascular endurance-building benefits — right in the convenience of your home. Makes a year round, consistent exercise program easily attainable. Eliminates the usual barriers of time, weather, chance of injury, etc. Also highly effective for weight control.

Better Than Running
NordicTrack gives you a more complete work out — conditions both upper body and lower body muscles at the same time. Fluid, jarless motion will not cause joint or back pains as jogging or running often does.

Better Than Exercise Bikes
NordicTracks stand-up skiing motion more uniformly exercises large leg muscles and also adds important upper body exercise. Higher pulse rates, necessary for building fitness, seem easier to attain because the work is shared by more muscle mass. The NordicTrack also keeps more muscles in tone.

Even Better Than Swimming
NordicTrack more effectively exercises the largest muscles in the body, those located in the legs and buttocks. These muscles main function is to lift and propel the body in the standing position. When swimming, the water supports the body thus preventing these muscles from being exercised as effectively as when they support the body in a standing position.

A Proven, high Quality Durable Product
Ruggedly constructed, NordicTrack is quiet, motorless and folds compactly for storage. Separate arm and leg resistances. NordicTrack is in its 5th year of production and is used in thousands of homes and many companies. We manufacture and sell direct. Our No-Risk 15 day trial guarantee shows our confidence in your being pleased with the performance and quality of the NordicTrack.

This year, give someone you love a gift for better health.

Getting Ready for Halley

Scientists have already begun making plans to observe this born again and again comet, due back in 1985-86

by Stephen P. Maran

"We've been looking for the last three years and we intend to look again in the coming season," said Michael Belton, referring to the current search for Halley's comet. An expert on planets and comets at Kitt Peak National Observatory in Tucson, Arizona, Belton is leading an attempt to make the first sighting of Halley's comet before its grand sweep past the earth and the sun in 1985–86.

Halley's comet has passed this way before; its last trip was in 1910. There are several scientific reasons for trying to make the earliest possible sighting of this previously known comet on its upcoming trip; among them are the desire to determine its physical state while far from the sun, the opportunity of measuring the size of the nucleus before it starts shedding material and gaining increased knowledge of the comet's orbit as a navigation aid for planned cometary space missions, and to assist in pointing the Space Telescope correctly. There is also the nonscientific reason that whoever is first to sight the comet will be assured of a place in astronomical history. The most famous comet observation of all time was made by an eighteenth-century German farmer, Johann Palitzsch, who was first to spot Halley on its trip through the inner solar system in 1758. Without that feat he would surely have remained unknown. Instead, Palitzsch is remembered in any number of historical accounts and books about comets.

Palitzsch upstaged the professional astronomers of 1758 by sighting Halley's comet on Christmas Day, on its first return following the prediction by the English astronomer Edmond Halley. The return not only verified Halley's prediction but also lent increased weight (if I may use that phrase) to Isaac Newton's theory of gravity and the gravitational effects on the motions of objects in space. Needless to say, the return had been eagerly awaited by the scientists of the world. So much so that Voltaire is said to have quipped that "astronomers never went to bed in 1758 for fear of missing the comet" (see "The Comet Syndrome," *Natural History*, December 1980).

This time around, however, the professionals are not about to be upstaged. Belton, for example, is using the 4-meter (159-inch) Mayall Telescope at Kitt Peak, equipped with a sensitive television camera that makes time exposures. Also, a group at the Mount Palomar Observatory in southern California is employing the famous 200-inch Hale telescope, together with an advanced solid-state detector "chip," which is refrigerated to within a few degrees of absolute zero to attain maximum sensitivity. No amateur, as far as is known, can command comparable instrumentation.

The predicted brightnesses of comets are always uncertain, as was underlined when great visibility was anticipated for comet Kohoutek (see "A Funny Thing Happened to Comet Kohoutek," *Natural History*, March 1974), but failed to develop. Nevertheless, for what it's worth, the predicted brightness of Halley's comet this fall, when Belton and others will continue to search, is 24th magnitude. This is about sixteen times (or three magnitudes) fainter than the dimmest stars and galaxies on the Palomar Observatory Sky Survey, which

A new and original work in porcelain
by the world's foremost portraitist of butterflies

T·H·E MEADOWLAND BUTTERFLY VASE

BY JOHN WILKINSON

In fine porcelain,
hand-decorated with pure 24 karat gold.

Your commission must be entered by
November 30, 1981.

The British artist, John Wilkinson, has been described as "the most outstanding portraitist of butterflies in the world today." And he is widely regarded as one of the foremost nature artists of our time.

Now this celebrated artist has designed his *first* work of art *in porcelain*: The Meadowland Butterfly Vase. This new work is a significant contribution to the porcelain medium, and is certain to be a source of lasting pleasure to any collector who possesses it. Furthermore, it will be a magnificent accent to any room in the home.

The Meadowland Butterfly Vase will be crafted in fine white porcelain—ideal for portraying the rich colors and graceful lines of Wilkinson's art. For his subject, the artist has chosen the loveliest butterflies that are seen in a sunny spring meadow. The Admiral, with its golden wings and distinctive black markings. The Painted Lady, softer in tone and elegantly graceful in flight. The Mourning Cloak, dramatic in tones of deep rust, blue and yellow. And the Purple Wing, aptly named for the shimmering beauty of its colors.

The artist has not only depicted the variety of shades and tones of the butterflies—using 16 different colors—but has captured the atmosphere of the English countryside as well. The height of the vase (11¼") provides ample room for this superb depiction. And, to add the final touch of refinement, the vase will be *hand-decorated* with a band of *pure 24kt gold* surrounding the crown and the base.

The Meadowland Butterfly Vase will be issued exclusively by Franklin Porcelain, and the responsibility for its creation has been entrusted to Franklin Porcelain of Japan, where there is a thousand-year-old tradition of crafting vases in fine porcelain.

A LIMITED EDITION. Advance orders for the vase are being accepted until November 30, 1981. A later announcement of this work will be made, but no orders will be accepted after the end of 1982. The issue price is $95, plus $3 shipping and handling, payable in four monthly installments of $24.50 each. The vase will be accompanied by specially written reference information and a Certificate of Authenticity.

To enter your commission, be sure to mail your order to Franklin Porcelain, Franklin Center, PA. 19091, by November 30th.

Vase shown smaller than actual size of 11¼" high. Hardwood stand included.

Halley's comet, May 4, 1910

means that the comet seekers will be scanning uncharted skies as they attempt to locate Halley's comet.

Even the faintest already charted stars, the Palomar Survey's 21st-magnitude objects, are so much brighter than the anticipated brightness of Halley's comet this fall that these extremely faint stars represent sources of interference in the comet search. Stars and galaxies this faint are also very numerous; they literally pepper the sky. Thus the strategy of searching for Halley's comet at its present vast distance, well beyond the orbit of Saturn, consists of examining the Palomar Survey photographs to find those places along the comet's predicted track where the faint but potentially interfering stars are least numerous. Observations are then scheduled for the nights when the comet's track will take it to those points. The most favorable night of the current season at Kitt Peak, Belton says, will be December 25—shades of Johann Palitzsch. Unfortunately, as one of several economy moves, the Kitt Peak Observatory recently adopted a policy of shutting down at Christmas.

Intensive observations of Halley's comet will begin in 1985 as it brightens while moving in toward the sun, making its closest approach to the earth in late November, then rounding perihelion (the closest point to the sun on the

Yerkes Observatory

comet's orbit) in February 1986. During 1985–86, the comet will be observed worldwide by NASA's International Halley Watch, a coordinated program of measurements and photographs by optical and radio telescopes strategically located to maintain an hour-by-hour survey of Halley's changing form and spectral emissions. Astronauts may pilot the Space Shuttle in a low Earth orbit as onboard telescopes focus on the ultraviolet radiation from the comet. Ultraviolet rays carry much information about cometary atoms and molecules, but cannot penetrate the earth's atmosphere and thus must be observed from space. If all goes well, the Space Telescope, a large, free-flying spacecraft carrying the most powerfully equipped telescope ever made, will be dropped into Earth orbit by the Space Shuttle in mid-1985. It too will observe Halley's comet.

The most exciting plans, however, involve the first attempts to send space vehicles to fly past the comet. At least three missions to be launched toward Halley's comet are currently in the works: one to be controlled by the Soviet Union, one by the Japanese, and one by the European Space Agency. The Soviet mission apparently comprises two spacecraft, which will fly to Halley by way of the planet Venus. The other missions involve one spacecraft each. As this column was being written in early

The Chivas Regal of Liqueurs.

Chivas Brothers make the world's finest Scotch. And the same renowned Chivas quality and tradition goes into its equally-regal Lochan Ora Liqueur. With a unique taste all its own. Lochan Ora is to be lingered over—sipped slowly, savored fully. It's expensive but, then, good taste invariably is.

Lochan Ora.

The Imported Liqueur from Chivas Brothers.

70 PROOF • IMPORTED BY GENERAL WINE & SPIRITS CO N Y N Y

summer of 1981, NASA had no approved mission to Halley, but authorities were discussing a possible American space probe capable of taking more and better photographs than the "foreign" craft and equipped to collect cometary particles for return to Earth and chemical analysis in laboratories on the ground.

Despite all of the above, Belton and the other early Halley seekers are not jumping the gun. It is important to locate and observe the comet as soon as possible to determine its "far out" state, meaning its physical condition while still far from the sun and the solar influence. In the next few years, as the nucleus of the comet—a ball of frozen water and the ices of other substances, mixed up with a fine powder of rocklike dust—approaches the inner solar system, the sun's rays will warm it. Evaporating gases will form the head, or coma, dwarfing the tiny nucleus, and will stream backward from the coma in the direction opposite the sun, to form a yellow dust tail and a blue plasma tail. The latter will be composed of electrified gases and can be expected to show abrupt changes of form as the onrushing Halley encounters disturbances in the solar wind.

The nucleus is the only part of a comet that returns from one passage around the sun to the next. All the gas and dust of the coma and the tails is lost in space. Each time Halley's comet returns from the outer reaches of the solar system (its aphelion, or point farthest from the sun, is beyond the orbit of Neptune), its nucleus sheds material to form a new coma and new tails. As a result, the nucleus is gradually shrinking, and one day it will no longer exist. It may split apart, crumble, or just plain vanish. Nobody knows. A few astronomers, including those mainland China researchers who have analyzed ancient Chinese records, claim that Halley has been gradually fading over the centuries, perhaps due to the shrinkage effect, but this conclusion has not been clearly substantiated.

If the searchers succeed in finding Halley's comet while it is still far from the sun and before the coma has formed, their observations should reveal just how large the nucleus is. It's a fairly simple matter: we know how bright the sun is, so the observed amount of reflected

Genuine Uncut
2 CARAT DIAMOND

Exquisitely Captured in Solid 14 KT Gold
An Unforgettable Gift. Only $199

Now, you can give a Natural Beauty GENUINE uncut 2 carat diamond in a 14 KT gold cage for only $199.

The Diamond Pendant is so unusual it will be admired and commented upon by all who see it. To be worn proudly on all occasions by any woman who covets a 2 carat diamond.

A polished gemstone diamond as large as this, would be worth thousands of dollars. But because these are selected rough, uncut diamonds — just as they come out of the diamond fields -- we are able to offer them at an amazing price. No two diamonds are exactly alike, all are guaranteed to be genuine and weigh at least 2 carats.

The Natural Beauty 2 carat uncut diamond caged in solid 14 KT gold is an exclusive of Columbia Minters — known for quality and value.

Order yours today — due to the ever changing price of diamonds on the world markets this exceptional price cannot be guaranteed beyond November 30, 1981. Your complete satisfaction is guaranteed or return within 10 days for a full refund.

Please specify Box, Triangle or Teardrop setting on order form.

VALID ONLY UNTIL NOV. 30, 1981

sunlight from the Halley nucleus, at its known distances from the sun and the earth, will tell how big the nucleus must be. More accurately, the reflected sunlight will provide an estimate of the nucleus size that depends on the albedo, or reflectivity, of the nucleus. A small, light-colored nucleus would reflect more sunlight than a larger, darker nucleus. Further, the surface texture will affect the amount of light reflected in different directions. Thus, a nuclear surface covered by many tiny particles—whether light or dark—would reflect light differently from a smooth, icy surface of the same light or dark shade.

Fortunately, the albedo can also be measured. In November 1980, Belton looked in vain for Halley's comet and concluded that he might have detected it had it been as large as sixteen miles in diameter. (The Palomar team came to a similar conclusion.) That's no surprise, for modern cometary scientists believe that the nucleus of even a big comet such as Halley may be no more than a few miles across although estimates published not many years ago were larger. Once the coma forms as the nucleus approaches the sun, it will be

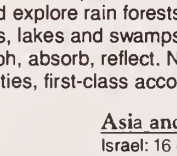
Wild Mammals
of Northwest America

by Arthur Savage and Candace Savage

Did you know that: porcupines can sing? beavers build mud pies to mark their territories? coyotes and badgers sometimes hunt together? wolverines have been known to kill bull moose? mountain goats make a game of turning somersaults? These are only a few of the fascinating facts revealed in *Wild Mammals of Northwest America.*



This attractive, informative volume —illustrated with more than one hundred large color photographs— explores the behavior, ecology, and natural history of seventy different North American mammals.

The authors combine extensive knowledge with a natural love of the outdoors to instill in the reader a new appreciation of the uniqueness and importance of every animal. They supplement the text with a large selection of the finest American and Canadian nature photography, all reproduced in living color, and sixty range maps illustrating the present distribution of all of the species.

$25.00 through December 31, 1981
$27.95 thereafter

difficult to separate the brightness of Halley's nucleus from the brightness of its coma and thus to gauge the size of the nucleus.

As the comet rounds the sun and displays the full panoply of cometary phenomena, as I think it will, Halley will shed a huge amount of ice, dust, and gases. The quantities of each will be determined by the many observations that are planned. Finally, as the comet recedes into deep space, to return next in the second half of the twenty-first century, it will shed its coma and tails, permitting a final glimpse of its born-again unadorned frozen nucleus.

If all goes well, the planned studies of Halley's comet may tell us what a cometary nucleus is really like. Although it is generally believed to be a "dirty snowball" of ice and rock dust, recent ground-based observations have raised some doubts. In fact, one paper presented not long ago at a comet conference in Tucson was provocatively titled "Where Is the Ice in Comets?" Infrared measurements from several observatories indicate that comet nuclei have the same general reflective properties as many asteroids. Yet asteroids have no atmospheres (comets do—the coma, or comet head, is an atmosphere) and surely are made of rock, while the presence of frozen water and other icy substances somewhere in the nucleus of a comet is proved by the fact that when the nucleus nears the sun, the coma forms around the nucleus. Current thinking holds that volatile materials sometimes are shed from the nucleus surface, leaving an outer crust of rock dust. According to this reasoning, the gases that stream outward to form the coma of a crusted comet evaporate from ices located below the surface of the nucleus and flow out of it through tiny channels in the crust. This would account for the observed infrared reflectivities and explain the coma, but the idea is definitely in need of verification. Measurements from a spacecraft close to the nucleus of Halley's comet, if any spacecraft gets there, could answer this question. One of the problems, of course, in approaching a cometary nucleus is the danger of collision with numerous small, or a few large, rock particles.

An early sighting of Halley's comet will help astronomers chart its path more closely. In the past, slight deviations from the expected path have led some astronomers to claim that the comet was slightly off track due to the gravitational pull of an as-yet-undiscov-

ered Planet X, located somewhere beyond Pluto. This claim has been rejected, although there still may be a little planet out there, too small and far away to noticeably disturb Halley. The comet does deviate from a precisely predictable path because evaporating gases give it some propulsion of its own. A reasonably accurate path, computed early thanks to an early sighting, might enable ground controllers to steer their space probes closer to the comet, and to point the Space Telescope with increased exactness so as to track Halley better.

There is special interest in determining what, besides water ice and rock dust, Halley or any comet is made of. Many atoms and molecules have been observed in the heads and tails of comets, but most of them are so-called daughter products. They are fragments of larger parent molecules, which evaporate from the nucleus and are then swiftly broken into daughter products by the sun's ultraviolet rays and by collisions with other particles. To identify most of the parents, it will be necessary to point or steer the sensing instruments into Halley's inner coma, where the parents can still be detected before they disrupt.

The viewing conditions for Halley in 1985–86 will not be as favorable as they were during its 1910 appearance. When the comet is brightest near perihelion in February 1986, it will not be observable from the ground. Nevertheless, past experience assures me that we will soon be receiving glossy brochures advertising comet-viewing cruises, and that suitably decorated Halley T-shirts, first-day postal covers, souvenir plates, bumper stickers, and crystal beer mugs cannot be far behind. At least one group will announce the end of the world, as is done every time a famous comet appears. Despite the impending hoopla, however, serious scientific investigations are in the planning stages and under way, and much should be learned.

Comets are widely believed to be the frozen debris of the material from which the sun and planets formed. If so, the intensive study of Halley's comet over the next few years may establish the facts we need to take us back five billion years in time to the origin of the solar system.

Celestial Events

by Thomas D. Nicholson

The Moon The waxing crescent moon decorates the western sky at sundown in early November, passing through Sagittarius on the 1st and 2nd, and entering Capricornus to become the first-quarter moon on the 4th. Full moon is on the 11th, and the waning gibbous moon is above Aldebaran, in Taurus, on the 12th. On the 17th and 18th, the last-quarter moon passes Regulus in Leo, as the moon and the star rise shortly before midnight. New moon is on November 26, and the crescent moon of the next cycle should be seen on the 29th and 30th. In early December, first-quarter moon is on the 4th, full moon on the 11th. Perigee moon (nearest the earth) is on November 12 and December 10, apogee (farthest from the earth) on November 26 and December 23.

Stars and Planets The planet scene has clearly shifted into the morning sky this month (except for Venus), focused in Virgo, where Jupiter and Saturn cluster on either side of the bright star Spica. Look for the three from before dawn until they fade in the morning twilight. They rise as a triangle about four hours past midnight; Saturn will lead them, followed by Spica (to the left) and Jupiter (easily the brightest of the three). During the first week of November, Mercury passes through the group to make it a "four-star" event (three are actually planets, of course), and late in the month the waning crescent moon highlights the trio (see illustration below). Venus is the only bright evening planet. It reaches greatest easterly (evening) elongation on the 10th, which ordinarily places it in the best position for viewing as an evening star. But this evening configuration of Venus is poor even at its best. Were it not for Venus's brilliance, it might go unnoticed. But bright it is (approaching its greatest brilliancy in mid-December), so don't be surprised to see that beacon flash out in the west-southwest any evening during late twilight if the western sky is clear or partly cloudy.

November 1: Look for the "teapot" of stars that marks Sagittarius, just below the crescent moon.

November 1–2: The Taurid meteor shower reaches maximum tonight, during after-midnight hours. It is not particularly bright or numerous (about 15 per hour at maximum), but there is no moon to interfere with viewing.

November 2–6: Mercury reaches greatest westerly (morning) elongation on the 2nd, and this is a favorable morning cycle for the planet. Look for the planet near the "triangle" formed by Saturn, Spica, and Jupiter. Mercury (brighter than Spica, but less than half Jupiter's brightness) is closest to Spica on the 2nd, closest to Jupiter on the 5th. Binoculars will help. By putting Jupiter in the center of the field, Mercury should be easily visible on the 4th, 5th, and 6th. Spica is below and to Jupiter's right and much more distant than Mercury on those mornings.

November 12: Expect stronger than usual tides today and tonight as the effect of the perigee moon adds to the spring tide accompanying the full moon of the 11th.

November 16–17: The last-quarter moon will brighten the after-midnight sky during maximum of the famous Leonid meteor shower. This is also not a very productive shower (15 per hour at maximum in normal years), but the meteors are swift and often very bright. You should see some, with patience, despite the moon.

November 22–23: These are the mornings to watch the waning crescent moon pass the trio of Saturn, Spica, and Jupiter. The moon is nearest to Saturn on the morning of the 22nd, and to Jupiter on the 23rd, passing above both.

November 30: The new crescent moon will guide you to Venus tonight. Look below the crescent as it becomes visible in the western twilight sky.

December 10: Mercury is in superior conjunction with the sun.

December 11: Another perigee spring tide occurs.

December 13–14: The relatively productive Geminid meteor shower (50 per hour) will be partly spoiled by the brightness of the full moon.

Editor's Note: The Celestial Events Sky Map in the October issue shows the evening constellations and stars for this month and gives the times for use.

Helmut Wimmer

Jupiter and Saturn, prominent evening stars this past summer, have now shifted to the morning sky, where they join the star Spica this month, rising in the east and visible from before dawn until twilight. Mercury passes the three objects in early November, as it goes through a favorable "morning" elongation, and the waning crescent moon highlights the trio in late November. This view shows the objects in the morning sky at about 5:00 A.M., looking east.

"Planet Earth has a furnace inside," says Glen E. Campbell, Gulf's Geothermal Supervisor. "The heat is generated by the natural radioactive decay of elements deep in the earth, and is conducted outward toward the surface.

"But the earth's crust isn't the same thickness everywhere. So in some places, this geothermal energy is buried miles deep, and in other places it comes right to the surface as volcanoes, geysers or hot springs.

"In many areas of the world, including the western U.S., geothermal resources hot enough to generate electricity come fairly close to the surface. In one such area, at Steamboat Springs, near Reno, Nevada, Gulf and another energy company are working on various techniques for extracting heat from the earth and putting it to work generating electricity.

"The potential is tremendous. Government figures show that the geothermal resources within the U.S. could free roughly a million barrels of oil per day for other uses."

Geothermal energy could be a big step toward energy independence. It's part of the business Gulf is in: energy for tomorrow.

Gulf

Gulf people: energy for tomorrow.

Hare Trigger

Toxins produced by heavily browsed plants may play a critical role in regulating the ten-year snowshoe hare cycle

by John P. Bryant

In the spring of 1911, the naturalist Ernest Thompson Seton was traveling north from Winnipeg, Manitoba, to begin exploration of the Slave River region in subarctic Canada. As seemingly endless miles of dense black spruce forest and fire-scarred shrubland slid silently past his train window, he noted in his journal that "last year had been . . . a year in which the ever-fluctuating population of Northern Hares had reached its maximum . . . nine-tenths of the bushes in sight . . . had been barked at snow level. . . . But the fact that we saw not one rabbit shows that the 'plague' had appeared, had run its course, and nearly exterminated the species in this particular region."

Thus Seton described the crash phase of the ten-year cycle of the snowshoe hare (*Lepus americanus*)—the most striking of the cyclic fluctuations that characterize grouse and small mammal populations of the North American and Eurasian subarctic regions.

Seton and other naturalists observed long ago that during the peak phase of the cycle—when hares are most abundant—hare populations frequently exhaust their winter food supply. Recent work has confirmed this observation and suggests that the key to what triggers the hares' decline may well lie in the interaction of the hares and their food. This interaction, however, appears to be more complex than a simple depletion of the hares' winter browse supply. My research and that of my associates at the Institute of Arctic Biology at the University of Alaska indicates that woody plants respond to severe hare browsing during the peak of the cycle by producing toxic metabolites and that this response may play a significant role in the regulation of the hare cycle.

Answers to the question of what drives the snowshoe hare cycle are far from uniform. Ecologists have been studying the cycle for more than fifty years, and most feel the problem has still not been satisfactorily resolved. Certain aspects of the cycle, however, are well established. Snowshoe hares have enormous potential for rapid increase in numbers (in favorable habitats, hundredfold increases have been recorded during a five-year period). At the low phase of the cycle, the hare population declines to vanishingly low numbers. In one area, for example, hare numbers were estimated at 2,000 per 100 hectares during the peak of the cycle and as low as 20 per 100 hectares at the crash. The period of the cycle may vary from region to region and from cycle to cycle (it ranges from 8 to 12 years, with about a 9.6 year mean), but within a region, hare populations rise and fall with a high degree of synchrony.

Many candidates for the mechanism that drives the cycle have been proposed—from weather patterns and cyclic wildfires to increased aggression among the crowded hares and increased predation and disease. Several of these theories provide partial answers, but until the recent work on the interactions of the hares and vegetation, I believe none has pinpointed the factors that trigger the decline or determine the period of the cycle.

Weather, for example, may perturb the cycle, and thus modify the amplitude of its oscillations, but it does not appear to cause it. Detailed studies have not revealed a simple, consistent relation between boreal forest weather patterns and the periodicity of the cycle.

The snowshoe hare gets its name from its large, hairy hind feet, which facilitate travel across snow. Its powerful hind legs enable the hare to flee from danger with long leaps and considerable speed.

Pat Powell, Aperture

Weather could drive the cycle indirectly. Lightning-caused fire is the single most important initiator of boreal forest succession, and early successional forests provide ideal hare habitat. Nearly fifty years ago, Wallace Grange, an early student of snowshoe hare ecology, suggested that the cycle is driven by cyclic wildfires, and there is evidence to support this theory. A strong correlation, for example, exists between the periodicity of wildfire in the Canadian boreal forest and the periodicity of Canada lynx pelt returns recorded by the Hudson's Bay Company.

The connection, however, is probably not as direct as Grange supposed. In western Alaska, the hare cycle is pronounced in riparian willow habitats, which are produced by spring flooding and ice scouring, but fire in the region is a relatively rare event and is probably not in phase with the hare cycle. Moreover, if a continent-wide fire cycle did exist, it could hardly provide the explanation for regional hare cycles that are often out of phase with each other. Nevertheless, there is no question that by creating large expanses of ideal hare habitat, fire strongly affects the potential for extreme expressions of the cycle. Flooding and insect outbreaks are other forms of disturbance that can set boreal forest succession in motion and thus provide the environment in which the hare cycle operates.

Population ecologists now generally agree that the hare cycle is density dependent, but they have widely divergent views as to what initiates the decline in the population once the number of hares per unit area in a region approaches some critical upper density. One school of thought holds that the hares have evolved intrinsic population regulation mechanisms driven by aggression. Increased aggression between hares at times of high density may lead either to psycho-physiological stress in the submissive animal, which causes failure of the adrenal gland and, ultimately, death or to dispersal of submissive individuals into habitats where the probability of survival is low.

Another school maintains that rather than controlling their own numbers, the hares are regulated by food shortages, disease, parasitism, predation, or some combination of such constraints. A model suggested by some ecologists predicts that an increase in hares is followed by an increase in hare predators—for example, Canada lynx, red fox, great horned owl, and goshawk—until the hare population can no longer withstand the predation rate and crashes. Following the disappearance of the hares, predators starve or emigrate to more rewarding hunting grounds. Released from intense predation, the hare population rebounds, and another oscillation of the cycle begins. Although appealing because of its biological and mathematical elegance, this model does not appear to be a sufficient account of the cycle's mechanism. Given the hares' tremendous capacity for population increase, even the combined toll of all their potential predators would be unlikely to contain an expanding hare population unless some more fundamental constraint had first initiated the decline. Increased predation, disease, and parasitism may aggravate the hares' decline, but they cannot cause it.

A more likely explanation seems to be that the decline phase is initiated when the hares destroy their preferred winter food, the twigs and bark of disturbance-adapted early successional trees and shrubs. The most fascinating aspect of the cycle, however, is, not that the hare population overshoots its food supply and subsequently crashes because of malnutrition, but the length of time—at least one hundred years and probably much longer—that the subarctic populations have exhibited an approximately ten-year periodicity.

Ecologists G. Evelyn Hutchinson of Yale University and Robert May of Princeton University have proposed that such cycles are a result of the delay with which species respond to changes in their populations or in the populations of interacting species. If an herbivore population, for example, is slow to adjust to a decline in the plant populations on which it feeds, it tends to overshoot the food supply and undergo a malnutrition-caused, overcompensatory crash. The extent of the crash and the speed of the recovery depend, in part, on just how long the delay is, relative to the periodicity of the cycle. Chaotic, violent oscillations, which can lead to the extinction of the herbivore, begin to occur if the delay is long enough. Shorter delays produce less extreme oscillations. When, for example, some property of the vegetation recovery process retards the recovery of the herbivore population for a length of time equivalent to one-fourth the period of the cycle, the oscillations will be marked enough to produce a severe crash of the herbivore population, but not so severe as to prevent the herbivore from rebuilding to its previous peak. Hutchinson and May propose that the rise and fall of the snowshoe hare is an example of this kind of cycle. According to this theory, since the period of the hare cycle ranges from eight to twelve years, the hares should take two to three years to respond to the recovery of the plants. My evidence suggests that this is the case.

What sort of mechanism could con-

W. E. Ruth, Bruce Coleman

At the peak of the ten-year snowshoe hare cycle, the woody plants preferred by the animals are overbrowsed. In response, the plants produce shoots unpalatable to the hares. The deterioration in the food supply appears to last long enough to cause a crash in the hare population.

W. E. Ruth

tinue to keep the hare population down once the vegetation begins to recover? To answer this question, my associates and I have been investigating the interactions between snowshoe hares and the woody plants of the boreal forests in which they live. Snowshoe hares, like all subarctic browsing mammals, reach high densities only in habitats that contain patches of early successional vegetation. While they do inhabit late successional black spruce (*Picea mariana*) forests and alder (*Alnus* spp.) thickets, hares are most abundant where both dense late successional vegetation and early successional plants are found. Within this mosaic environment, the hares use late successional vegetation primarily for shelter from severe winter storms and predators. They move once at dusk and once at dawn into the adjacent patches of early successional vegetation to feed on willows, birches, poplars, and jack pines, their preferred winter food. Unless they are starving, they feed lightly, if at all, on black spruce and green alder (*A. crispa*).

In controlled feeding experiments, hares can be maintained indefinitely under winter conditions if fed a diverse, highly palatable diet of the mature parts of early successional browse species. By contrast, they survive only a few days when fed nothing but alder and other, less palatable late successional woody plant species. Malnutrition is an unlikely cause of the hares' rapid deterioration. Alder is a nitrogen-fixing plant whose winter dormant twigs contain very high concentrations of nutritious proteins and soluble carbohydrates. Its chemical content would appear to make alder the most nutritious food available, yet it is one of the least-browsed subarctic woody plants. Why?

Knowing that black spruce and alder are noted for their high tissue concentrations of toxic secondary metabolites, I decided to test the possibility that snowshoe hares avoid feeding on late successional trees and shrubs because of the plants' toxicity. I extracted terpene and phenolic resins from both green alder and black spruce and incorporated the extracts into commercial hare food, which I then offered to both free-ranging and captive snowshoe hares. In all the feeding experiments, hares avoided the resin-treated food but eagerly ate the unadulterated control food. Moreover, captive hares that were offered only resin-treated food refused to eat for several days, and when hunger finally forced them to feed on the treated food, they lost weight even more rapidly than when they were eating nothing.

Subsequent experiments have begun to show why ingestion of these resins is so stressful to hares. Green alder resin contains relatively large quantities of pinosylvin methyl ether, a phenolic substance that appears to be repellent to hares and is known to be repellent and toxic to a variety of herbivores, from termites to rabbits. When wood that is normally heavily fed upon by tropical termites is treated with this substance—in quantities as low as one-tenth of one percent of the dry weight of the treated wood—the termites will not even approach the wood for at least two years.

The toxicity of these plants is partly a consequence of the conditions of extreme nutritional stress under which they grow. Many trees and shrubs adapted to growth on nutrient-deficient soils have slow turnover rates of twigs and leaves. Consequently, they experience less of the nutrient loss that accompanies the frequent shedding of leaves and twigs characteristic of woody plants adapted to growth on nutrient-rich soils. This nutritional conservatism, however, also means that a large fraction of the nutrient and carbon reserves of these plants is exposed year-round to above-

In winter, snowshoe hares seek protection from storms and predators beneath snow-laden, late successional trees such as spruce. For feeding, they prefer early successional species, including willow and birch.

Mario Grassi, AlaskaPhoto

ground herbivory and that the plants have limited ability to replace parts eaten by herbivores. Real or simulated hare browsing of late successional boreal forest trees and shrubs greatly reduces their reproductive output and results in high mortality levels. That these plants have evolved chemical defenses against herbivores is therefore not surprising.

Late successional trees and shrubs are not the only woody plants of the boreal forest that are toxic to snowshoe hares. Plant chemical defenses also play a crucial role in the interactions between early successional woody plants and hares but in a very different way. This difference may provide part of the explanation of the hare cycle.

During the winter of 1972–73, hare numbers around Fairbanks peaked and started to decline. David Klein of the Alaska Cooperative Wildlife Research Unit noticed that hares fed heavily that winter on mature early successional trees and shrubs but appeared to avoid the adventitious shoots, or stump sprouts, being regenerated by these preferred browse species. Furthermore, the avoidance seemed to be even stronger than the avoidance of black spruce twigs, which at this point in the cycle made up much of the diet of the declining hare population. Klein speculated that adventitious shoots were avoided either because they contained few nutrients or because they were toxic. To test these alternatives, he first confirmed experimentally that when equal quantities of both adventitious shoots and small-diameter, mature twigs of willows, poplars, and birches were available, the hares shunned the shoots but eagerly fed on the twigs. He then assayed the nutritional content of the twigs and shoots and found that the shoots had higher tissue concentrations of nutritional chemicals. Their apparent low palatability, Klein hypothesized, must be a result of their toxicity.

This startling experiment suggested to me that the browsing caused a defensive response in the hares' preferred browse species. Observations I had made about the relationship between Alaska paper birch (*Betula papyrifera* spp. *humilis*) and snowshoe hares supported this hypothesis. Alaska paper birch is a member of a group of birches characterized by an abundance of toxic resin glands in the one-year-old twigs of adventitious shoots and an absence of resin glands in the one-year-old twigs of mature plants. The foliar buds of both kinds of twigs contain high concentrations of resins. When hares feed upon the mature-plant twigs, they reject only the buds; when feeding upon the stump-sprout twigs, they reject the entire twig. Hares are the only herbivores I know of that exhibit such feeding behavior. I suggested that resins known to protect birch foliar buds against insects are extended to the twigs of adventitious shoots when the risk of hare attack is high. Subsequent experiments have shown that such an extension of chemical defenses is also characteristic of the highly preferred poplars and the much less palatable alders.

Many juvenile woody plants produce thorns or large quantities of toxic secondary compounds, which appear to deter herbivory. The highly complex controls over the progression from juvenility to maturity are far from clearly understood, but plant physiologists do know that in deciduous woody plants, the progression is reversible: severe pruning can cause a mature plant to revert to a juvenile form. As a part of the reversion, the plant will increase its production of defensive structures and substances. Since the hares' intense browsing of their preferred plants at the peak phase of the cycle is nothing more than severe pruning, reversion to juvenility may provide the physiological explanation for the defensive response turned up in Klein's experiments.

Such an induced defense appears to fit well into the overall adaptive strategy of early successional, disturbance-tolerant trees and shrubs. These plants store relatively large carbon and nutrient reserves in underground parts, such as roots, from which they can regenerate

Charlie Ott, Photo Researchers

Canada lynx and other predators can take a heavy toll of snowshoe hares. The hares' capacity to increase in number is enormous, however, and predation alone cannot cause the cyclic crash of the hare population.

aboveground parts destroyed by disturbance. Hare browsing can be viewed as a form of disturbance, so why, one might ask, do the plants respond to intense browsing by becoming toxic? The answer lies in another aspect of adaptation to growth on recently disturbed sites. A severe disturbance to a late successional ecosystem—wildfire, for example—opens up the forest canopy and releases large quantities of nutrients from the living and the dead vegetation. Early successional trees and shrubs then compete for the nutrients and the light to gain dominance in the opening and reach the forest canopy.

At this stage in their development, these juvenile browse species need to grow upward quickly, so they allocate much of their carbon to vertical growth and chemical defense against hare browsing; once out of reach of hares, they allocate more carbon to lateral development of the crown and production of seeds and less to chemical defense and vertical growth. In the event of intense browsing, however, plants can—by reverting to juvenile form—increase the allocation of carbon to defense. Without this ability, repeated regeneration of leaves and twigs at times of heavy browsing might stress the underground carbon reserves so severely that the plant could no longer respond defensively to browsing or compete successfully with other plants.

To the hare, the defensive response of its preferred browse species means a serious deterioration in the nutritional quality of its winter food supply. My experiments strongly suggest that this deterioration lasts for two to three years—the time lag predicted by the Hutchinson-May model of the hare cycle—even though only the one-year-old twigs of adventitious shoots appear to be highly repellent to hares.

The first year after heavy browsing, all the new twigs produced by these early successional woody plants are chemically defended and of little nutritive value to hares. Adventitious shoots grow rapidly, and in the second year of growth after browsing, the two-year-old twigs are no longer toxic, but they are usually more than 4 mm in diameter and have very high wood/bark ratios. Since most of the nutrients of the twig are stored in the inner bark, a high wood/bark ratio is associated with low nutrition irrespective of toxicity; these twigs are also essentially useless to the hares. The only small-diameter twigs available during this second year are one year old and thus chemically defended. In the third year of growth, however, a few lateral branches support a modest number of small-diameter, two-year-old twigs that hares can feed on efficiently. After three years, this usable biomass increases rapidly, and the hare population can begin its recovery.

In the end, then, the cycle may be a consequence of the adaptation of boreal trees and shrubs to disturbance, and particularly to fire, but the fire–succession–hare connection seems to be tied more closely to the behavior of the plants themselves than was previously realized. The plants' ability to produce toxins—an ability so advantageous to them and so devastating to the hares—may occupy a pivotal place in the almost legendary ten-year population cycle of the snowshoe hare. □

In Praise of Plains

Early explorers told of being overwhelmed by the silence and vastness of the grasslands

by Marilyn Coffey

"I drink the wind like wine."
Hamlin Garland

The Great Plains region of the United States, where I was born and raised, is part of an enormous strip of flatland that stretches alongside the Rocky Mountain chain for more than three thousand miles, from the plateaus of northern Mexico to the Mackenzie River in subarctic Canada. In sheer extent, this North American grassland has no equal on earth although similar areas exist on other continents: the steppes of Siberia, the pampas of South America, the veldts of Africa. Shaped roughly like the crescent of the waxing moon, the Great Plains swells to its maximum in central United States, tapers to near points at its termini. Once, not much more than a hundred years ago, this plain was nothing but meadow, a tangled profusion of grasses and wildflowers broken only by an occasional tree-lined river or stream meandering slowly downslope or by buffalo and Indian trails, which crisscrossed each other in an intricate network that led from waterway to waterway.

I never actually laid eyes on virgin prairie when I was young. Except for scattered fragments, some of which can still be seen today, virtually all of the native grassland of the central plains had been plowed under long before I was born. In fact, my great-grandfathers James Thomas Coffey and Isaac Matts Smith were two of the hundreds of small farmers who resolutely overturned the sod, Smith in 1883 and Coffey in 1885, burying the last generation of native meadow deep in the Tertiary soil out of which its ancestors had sprung millions of years ago. But that didn't matter to me. I knew how the prairie must have been, not because I had been told, but because some vestige of it seemed to cling to me, as though knowledge of

A storm sweeps across the Plains.
Jim Brandenburg

what the land had once been entered me through my very pores, carried, perhaps, by the ceaseless wind. It was, paradoxically, the most beautiful land I had ever seen.

Reports of the virgin prairie's beauty, written by early explorers and naturalists, confirm my childhood intuition. Journal entry after entry describes the vast meadows as profusely decorated—"gilded"—with myriad flowers. The fields of Quivira, in central Kansas, were "covered with flowers of a thousand different kinds, so thick that they choked the pasture," wrote the Spanish explorer Oñate in 1601. "A thousand young flowers gemmed the grassy plains," wrote Thomas J. Farnham some two hundred years later. There were the sky blue flowers of spiderwort and the light red phlox, the "showy" yellow sunflowers and purple asters, fields full of white flowers and long garlands of wild roses, whose single corolla of pale pink petals surrounded a chunky golden stamen and whose fragrance lay heavy in the early spring air. "These vast plains, beautiful almost as the fancied Elysium, were enamelled with innumerable flowers," wrote English botanist Thomas Nuttall in 1819, "an uncommon variety of flowers of vivid tints, possessing all the brilliancy of tropical productions."

As profuse and varied as the flowers, although less spectacular, were the grasses, which ranged in height from the short stubby buffalo and grama grasses of the semiarid western prairie through the thick luxuriant mixed grasses of the subhumid central prairie, about ten inches high, to the great swaying blades of bluestem and Indian grass in the humid eastern prairie, blades that rose eight feet high. These heights were directly proportional to the rainfall, which tapers off from east to west, as can be seen today by the commercial grasses that have replaced the native strains. In the east, corn, a grass, rustles higher than a man's head, while the less humid central region is renowned for another, shorter grass: winter wheat. The semiarid western prairie, then as now, was good primarily for grazing, its clumps of short grass mixing with prickly pear and with the sunflower: a tiny wildflower in the west, taller than a tulip in the central plains, and eight feet high in the east. The central plains, where I grew up, was a transitional area, dependent on the intermittent rain that never seemed to fall twice in the same place. In dry years, needlegrass and other short

Tom McHugh, Photo Researchers

Winter's blizzards, above, give way to spring's wildflowers, left.

grasses from the west would intrude to mix with the central prairie's June grass and wheat grass at the top of sunbaked ravines; in wetter years, bluestem would creep in from the east, taking hold along moisture-laden ravine bottoms.

This stunning panorama of wildflowers and native grasses, their species described meticulously by early botanists, would probably strike the modern eye as one vast impressionistic canvas swept by variegated colors that changed with the prairie's moods. How delicate this meadow must have appeared in the blue light of an early morning, as bland morning breezes bent the tips of grasses, displaying the muted colors of the blades' undersides. How vivid at midday, the sky as clear as in a Chinese painting, when through the crystal light, according to artist Thomas Mails, you could see a spot of color twenty miles away. Or after a shower when, according to Maj. Stephen Harriman Long, the grass was "gemmed with the reflection of innumerable pendant raindrops." And how serene under the purple light of a calm evening, when deer might be seen stepping through the shoals that separated sandbars on a meandering river like the Platte: a "stilly scene, like shadows of phantasmagoria, or Ossian's deer made of mist," wrote Henry Marie Brackenridge.

Not only did colors shift with the various moods of each prairie day but also with each season: white in winter, green in spring, yellow in summer, and red-orange in autumn, says Mails. But that simplifies the matter too much in a land where winter may look like a mirror as a sudden drenching of February rain turns the Plains into a continuous sheet of water. Or brown, as snow melts to reveal the stubborn remnants of the prairie grass, some of which live for twenty years. In early spring, the slender shoots of bright new grass may well sprout up a sharp and tender green in the winter-yellowed sward. But spring and autumn are when the wildflowers reach their peak of intensity, glazing the meadow with purples, pinks, red, yellow, and white. In the overplus of August's brittle light, sere stubble may suddenly mirage into an islanded lake, while through the October haze of a reddened Indian summer sun, the prairie colors are seen as though wrapped in smoke.

The beauty of the Great Plains, however, was not for everyone. The space I took for granted as a child, what the Plains Indians called the *waho*—the great circle of the horizon—was more than most newcomers, whose ideas of space had been formed in hilly, tree-studded country, could bear. "The first experience of the plains, like the first sail with a 'cap' full of wind, is apt to be sickening," wrote an early viewer, Colonel Dodge. More than one journeyer, in diary or letter, told of standing still and lonely, overwhelmed by the silence and vastness of the place. "Magnificent, though melancholy," wrote Henry Brackenridge in 1811, while Thomas Farnham noted, in 1839, that his eyes ached from his attempts to embrace the view. More than one writer mentioned a general feeling of emptiness or dwelt on their "nauseating" loneliness. Even Coronado, who must have been reminded of portions of his native Spain when he entered this dry, treeless land, expressed surprise at its scope, saying, "I came upon some plains so vast that in my travels I did not reach their end, although I marched over them for more than three hundred leagues"—nearly one thousand miles, as we measure land.

The Plains were most frequently compared, by early journal writers, to an ocean, an ocean where one swell melted imperceptibly into another. Some, like expedition leader Wilson P. Hunt, used this figure of speech literally. "The limits of the visible horizon," wrote Hunt, "are as exactly defined, and the view as extensive as at sea, the undulations on the surface of the earth here bearing no greater proportion in scale than the

Tom McHugh, Photo Researchers

Brian Milne

David Barnes, Photo Researchers

Above: Rabbit is obscured by grass. Right: Road divides plowed fields.

waves of an agitated ocean." Others were more poetic. Thomas Farnham called the Plains "vast savannahs, resembling molten seas of emerald sparkling with flowers, arrested while stormy and heaving, and fixed in eternal repose." Adopting a more tragic perspective, Abbe Emmanuel H. Domenech wrote, in 1860, that the grasslands of west Texas were "like an ocean of dark stunted herbs, in which not a single bush or bramble obstructed the view, where nothing marked a beginning or an end, and where all was mute and motionless." Some, like the young American Brackenridge, found the ocean comparison inadequate. "If the vast expanse of the ocean is considered a sublime spectacle," he wrote of the central plains in 1811, "this is even more so; for the eye has still greater scope." Or, as Hamlin Garland would put it decades later, "my eyes/Fasten on more of earth and air/ Than seashores furnish anywhere."

Those to whom the vast open space was not oppressive found it, as I did, exhilarating. "The nerves stiffen, the senses expand, and man begins to realize the magnificence of being," wrote Colonel Dodge, once he'd recovered from his seasickness. Brackenridge, who had stepped out onto the Plains from a riverboat on the Missouri, wrote: "Instead of being closed up in a moving prison, deprived of the use of our limbs, here we may wander at will. The mind naturally expands, or contracts, to suit the sphere in which it exists—in the immeasurable immensity of the scene, the intellectual faculties are endued with an energy, a vigor, a spring, not to be described."

Exhilaration, however, could tip quickly into terror, and often did, particularly when unprepared travelers first met the Great Plains thunderbird, that spectacular mythological creature that flies through the air with its eyes closed, its gigantic wings flapping out "peals of thunder which seemed to shake the earth to its center," thunder that visibly enraged the buffalo bulls that pawed the earth and bellowed as the big bird rumbled overhead. When the thunderbird blinked, the Indians said, great spears of sprangling lightning would flash out of its open eyes, leaving the pack animals to huddle abjectly together, heads drooping and limbs stilled, while humans trembled for their lives.

The Great Plains is justifiably famous for its violent thunderstorms, one of the more dramatic aspects of the region's changeable, highly versatile weather. The storms, typically of short duration, often produce downpours of three to six inches or more. The rain tends to be local, drenching the earth in one spot while the surrounding area remains dry. Most thunderstorms are caused when two of the region's three major air masses collide, when the cold dry air from Canada strikes either warm, moisture-laden air masses from the Gulf of Mexico or air that has swept across the Rocky Mountains, Pacific air masses that range from warm to cold, moist to dry. Most rain falls from April to July, with storms reaching their maximum in May or June, the months when most early travelers began their long treks into, or across, the Plains. As a result, early journals abound with tales of travelers drenched to their skins, spending cold, sleepless, wet nights, unable to find a bit of dry bedding or clothing among all their gear. Along the Platte River, famous for drawing thunderstorms, emigrants reported almost daily downpours in the spring of 1839.

Anyone who has seen a Great Plains thunderstorm in its full splendor knows that its most spectacular feature, the thing that distinguishes it most clearly from an equally violent downpour in the city, is that the storm can be seen coming from miles away. Indeed, the Plains area is so large that a storm, from a distance, can be perceived as a single entity, its black clouds churning, its

lightning jets leaping, its gray sheet of rain falling in a slanting torrent even while the sun shines directly overhead. Before the storm is seen, it can be heard, its thunder rumbling gently from a great distance. And before it can be heard, it can be felt—a shift in the temperature of the air, a certain silencing of the wind. "Excepting the sound of distant thunder, which was continual," wrote English naturalist John Bradbury of a prairie storm in May 1810, "an awful silence prevailed, and the cloud which had already spread over one half of the visible horizon was fast shutting out the little remains of daylight." As the cloud drew overhead, he noted that it was of "a pitchy blackness, and so dense as to resemble a solid body, out of which, at short intervals, the lightning poured in a continual stream for one or two seconds. Darkness came on with a rapidity I never before witnessed." He wrapped himself in a blanket and lay down on the open land. "The lightning," recorded Farnham of a storm in 1839, "was intensely vivid," as three black clouds, one in the southeast, one in the southwest, and one in the northeast, "rose with an awful rapidity towards the zenith." As he looked up, he saw the cloud "rent in fragments, by the most terrific explosion of electricity we had ever witnessed." Peals of thunder followed, as burning bolts leaped from cloud to cloud, enveloping the land in a "lurid glare."

Hail often accompanied these storms, although, curiously, the size of hailstones seems to diminish with the passing of time. In 1541 one of Coronado's conquistadors, Pedro de Castañeda of Náxera, reported hail in the southern plains "as large as bowls and even larger, and as thick as raindrops, that in places they covered the ground to the depth of two and three and even more spans." The huge stones destroyed the Spaniards' tents, dented their armor, bruised their horses, and broke all their pottery, a problem for the Spanish army since the local Indians, who ate only fruit and meat, had no use for crockery and could supply them with none. Many years later on the Plains, a report circulated of an Indian who had been knocked down by a hailstone the size of a goose egg. As for myself, although I stood on our screened-in back porch through many a summer storm with my father, a farm boy who never tired of watching it rain, and saw countless white stones fall from the sky and bounce across our green lawn, I cannot

say that I ever saw a prairie hailstone larger than a marble, although some were as big as taws. However, the folks over at Republican City swore they had seen hail the size of ping-pong balls, and they had cars with bashed-in windshields to prove it.

Less dramatic than the storms, but equally unnerving—at least for some—was the prairie's *trompe l'oeil*. Optical illusions, caused by the combination of a rarified, transparent atmosphere with distances so great that "only the curvature of the earth's surface limits the view," often fooled the eye of the inexperienced observer. Objects, which could be seen with remarkable clarity from a great distance, became strangely distorted. Some were magnified, so that a raven might be mistaken for an Indian or an antelope for the much larger elk. Some were diminished, so that the leafy tops of the line of timber along a distant river seemed to "wave and mingle among the grass of the wild swelling meadows." Some objects, such as tufts of grass or buffalo bones, were elevated, stretching up so high that they looked like humans. The first to mention this phenomenon was one of Coronado's chroniclers, who wrote that the land where buffalo roamed was "so level and bare that whenever one looked at them, one could see the sky between their legs, so that at distance they looked like trimmed pine tree trunks with foliage joining at the top." Sometimes, under the intense glare of a pitiless August sun, the "earth and sky seemed to blend." In its most extreme form, this illusion became a mirage, such as the one described in 1849 by Alonzo Delano: "The glare of the sun upon the distant plain resembled the waves of a sea, and there were appearances of islands and groves."

This "abnormal land" was home to me. As I was growing up, I knew no other world but the prairie's vast *waho*, its thunderstorms, its windblown fields. This natural habitat would render agoraphobia—the fear of open spaces—as incomprehensible to me as, many years later, my claustrophobia when ringed in by mountains or trees was to those who judged such restrictions "natural." Like a medieval woman, I was limited by the world I knew but knew not that my world was limited. □

Craig Aurness

A Least Tern Makes a Right Turn

With a little help from the Endangered Species Act, an imperiled California bird is on the road to recovery

by Barbara W. Massey

Photographs by George D. Lepp

One endangered animal that seems to have a good chance for survival is the California least tern (*Sterna albifrons browni*). This feisty bird, the smallest of its genus, is making a comeback, thanks to strong protective efforts on its behalf. The California least tern is one of three subspecies of *S. albifrons* that breed in the United States. On the eastern seaboard *S. a. antillarum* nests on beaches from Maine to Florida, its breeding biology very similar to the California least tern. An inland race, the interior least tern (*S. a. athalassos*) nests on sandbars in rivers of the Mississippi drainage system. The west coast birds breed from

San Francisco Bay to the tip of Baja California. All three subspecies are beset by problems, mostly due to loss of habitat, but thus far only the California least tern has been listed as endangered.

The California least tern has traditionally nested on beaches and salt flats adjacent to estuaries, feeding on small fish taken from a wide range of habitats—estuaries, open ocean, rivers, and lakes. The terns usually arrive in California in mid- or late April, and for several weeks engage in aerial courtship. One frequently observed aerial display is the fish flight, initiated by a male carrying a small fish and calling as he flies. He is joined by one and sometimes two other least terns (presumably females) for some fast and vocal high flying. Another spectacular display is the aerial glide—formation flying by a pair that rise high in a weaving pattern and then soar downward in unison in a beautiful glide. At night the terns congregate at roosting sites on beaches, using the same locations year after year. The ground phase follows aerial courtship and is characterized by acts that help cement the pair bond, with courtship feeding of females by their mates one of the most important rituals. Copulation is frequent at this stage. The male

Undaunted by the proximity of sunbathers, California least terns loaf on the beach in Venice, California. Developed extensively in recent decades, this coastal community was a tern nesting site until human disturbance finally drove the birds off the beach in the early 1960s. When 35 pairs reestablished a colony in 1977, however, protective fencing was quickly erected around the nesting area. About 150 pairs nested on the beach in 1980, making the colony the largest in the state.

often holds a fish in his bill throughout the precopulatory sequence, and the female reaches up and takes it from him at the moment of cloacal contact.

As the time for egg laying approaches, the pair begin to look for the particular spot where the nest will be scraped in the sand. They engage in elaborate scrape making, moving from place to place until the female finally selects a site to her liking and scrapes out a simple hollow for the eggs. From one to three eggs (usually two) are laid on consecutive days, after which both adults take turns at incubation duties.

The relative serenity of the incubation period is the lull before the storm. After about three weeks, the eggs hatch and the tempo quickens. The precocial chicks begin wandering away from the nest scrape a day or two after hatching. Their diet consists solely of small fish brought to them by both parents. Parents only feed their own chicks, and the chicks learn to respond only to the calls of their parents as they fly in with fish. Since the chicks are extremely mobile, and a colony of a hundred pairs of California least terns can have 200 chicks running around simultaneously, the communication system must be firmly established on the first posthatching day. The chicks are on the ground for about twenty days after hatching, eating voraciously and growing rapidly until they are mature enough to fly. During both the incubation and posthatching periods, the colony is extremely vulnerable, and eggs and chicks are regularly lost to ground and aerial predators. Disturbance by people can also have serious consequences during this time as the presence of intruders on the nesting grounds keeps adults off their eggs or away from their chicks. Once the chicks are airborne, the hazards diminish.

After fledging, the juveniles begin to fish for their own food, practicing in local ponds and still-water bays. It takes a lot of practice before they acquire the skills necessary to feed themselves, so parents continue to feed their young long after they have fledged. At dusk, adults and juveniles congregate at roosting sites on the beaches where they spend the night. These roosting areas and postbreeding fishing sites play an important role in the life history of the least tern, and must be protected along with the more obvious nest sites and adult fishing grounds. By August the nesting season is usually over and migration to wintering areas has begun. Family groups are maintained during migration, and adults can be seen feeding juveniles at fishing and loafing areas en route.

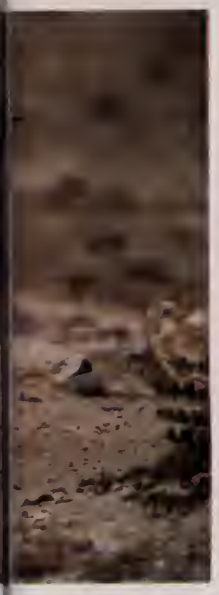
The least terns' predilection for nesting on beaches and foraging in estuaries was the major cause of their drastic decline in numbers. The tremendous growth of the human population in California after World War II, particularly along the southern coast, put pressures on the birds that they could not withstand. In terms of breeding habitat, undisturbed beaches became scarce and most of California's estuaries were dredged and converted into marinas. Colonies that once numbered hundreds of pairs were reduced to remnants or vanished altogether. But the terns showed remarkable adaptability and ingenuity in finding substitute nest sites;

As this least tern emerged from the egg, the first moments of its life were captured by the photographer. The chick's cryptic coloration provides a defense against predators.

In a sequence of courtship and mating, a male approaches a female with a fish. After much head moving and wing fluttering, the male mounts the female. During copulation the female reaches up and takes the fish.

they have nested successfully between runways on airports, on parking lots and freeway cloverleafs, and on an abandoned trash dump, to name just a few. Adaptability notwithstanding, the least tern was fighting a losing battle in southern California as coastal lands were relentlessly developed and would not have been around much longer if drastic steps had not been taken.

The passage of the federal Endangered Species Act in 1969 began a reversal of the downward spiral. The act covered not only species of endangered animals (for example, the California condor, *Gymnogyps californianus,* but also subspecies that were in jeopardy). California quickly passed its own act, and finally, there was legislation that could be used to assist beleaguered animals such as the California least tern. A list of endangered species and subspecies was drawn up by the U.S. Fish and Wildlife Service, the state of California followed with its own list, and the California least tern was on both lists.



My involvement with the birds began at this time. I was a middle-aged returnee to graduate school at California State University, Long Beach, retraining to become a field biologist. For a master's thesis project, I wished to do a field study, and my adviser, ornithologist Charles T. Collins, suggested the California least tern. It had just been listed as endangered, but there was almost no information on its breeding biology and, thus, no guidelines as to how to protect it. Several local breeding colonies made daily observations feasible. My commitment to the terns, in retrospect, was instant and total.

In 1971 the California Department of Fish and Game began to protect the birds during the breeding season and to fund some preliminary studies. A survey of nesting sites was made in 1971, and in 1973 the first statewide census was taken. The passage of the California Coastal Zone Act in 1972 resulted in the creation of regional commissions to monitor development along the coast and a statewide commission to hear appeals. The California Coastal Plan, written by the staffs of both the local and state commissions, was approved by the state legislature in 1976. A priority item in the plan is the preservation and restoration of coastal wetlands. Since its inception, the state commission has taken a strong stand on protection of coastal wetlands and endangered species and has supported all efforts made on behalf of the least tern.

The Endangered Species Act was much strengthened by Congress in 1973, and one of the results of the amended act was the formation of a recovery team to watch over the California least tern. Since 1974, the team has played a vital role in the turnaround in the fortunes of the tern (it is almost impossible to write about terns without at least one play on words). The team was charged with writing a recovery plan spelling out the procedures necessary to insure the survival of this endangered bird. One of the most important aspects of the plan was the delineation of habitats considered essential for successful breeding. Included were nest sites, fishing areas, loafing spots, night roosts—any place that was of importance in the breeding cycle and was in regular use by the birds during some part of their stay in California. The plan was completed in 1977 and approved by the U.S. Fish and Wildlife Service in 1980.

Protection of the terns' habitat is the core of the recovery plan. Currently, there are about a dozen nest sites under the protective aegis of a federal, state, or other public agency; the plan recommends secure nest sites in "at least twenty coastal wetlands ecosystems" throughout the birds' range. An annual census of the breeding population, surveillance of all colonies during the nesting season to spot and correct problems as they arise, creation of new nesting sites, research programs to learn more about the birds' breeding biology, exploration of Baja California during the spring to identify the rest of the breeding range, and exploration of the west coasts of Mexico and Central America to determine the wintering range are all aspects of the plan that have been implemented in varying degrees.

Since the first breeding census in 1973, the population has been monitored annually with funds made possible by the Endangered Species Act. About six hundred pairs were estimated in 1973 and for the next three years that figure remained stable. In 1977 there was a modest increase of about fifty

pairs and we were hopeful, but reserved judgment. Censusing techniques had improved, new colonies were being found, and the increase might simply reflect these factors and not be real. But the figures kept climbing in 1978 and 1979, and by 1980 more than nine hundred breeding pairs were counted. It is hearteningly apparent that protective measures are working.

With the increase in population came a need for new nesting areas. Creation of nest sites is an idea still in its youth, but decidedly past infancy. After several attempts that failed, but from which important information was obtained, two successful sites were created on islands in salt marshes in northern Orange County. They were used by the terns in 1979, 1980, and 1981. In all cases, the beaches associated with the salt marshes were heavily peopled during the summer months and no least terns had nested on them for more than thirty years. One of the sites was an existing landfill in the Seal Beach National Wildlife Refuge in Anaheim Bay, connected by a narrow causeway to the mainland. The rough surface of the island was leveled and topped with sand, and pairs of papier-mâché decoys were scattered about. One of life's more satisfying moments occurred when I saw a least tern land and offer a fish to a decoy. Soon there was a small group of nesting birds, and in early June 1979 the first chicks hatched. But as the season advanced, predators began to take a heavy toll of the chicks. By the end of the season the refuge managers knew that predator control was mandatory. In 1980, about a month before the terns were due to arrive, live traps were set around the island and twenty-nine skunks, five feral cats, three red fox, and two opossum were removed from the area, indicating the magnitude of the problem. An electric fence was then installed across the causeway. The measures proved reasonably effective against ground predators but no defense at all against birds of prey (American kestrels, burrowing owls, crows). Even though predation was a continuing problem, forty-three pairs of terns nested in Anaheim Bay in 1980 and produced a respectable number of fledglings.

At Venice Beach in Los Angeles another success story has unfolded during the past few years. In 1977, a resident of this beach-front community reported to the California Department of Fish and Game that several least terns nesting on the beach were being molested by dogs and people. Venice Beach is at the mouth of a former estuary, now almost totally channelized and converted into a marina. Once the site of a large nesting colony and now a heavily used bathing beach, Venice had not been used by the terns since the early 1960s. Concerted action by several agencies, prodded by concerned citizens of Venice, resulted in the erection of protective fencing around the few hardy pairs that were attempting to nest on the beach. The birds' response was immediate, and by the end of the 1977 season there were 35 pairs. The terns came back and nesting was successful the following year. (It has been our experience that if the terns succeed in hatching chicks they will usually return the next year, even if none of the chicks survive to fledge.) The colony has grown with giant steps

A male presents the small fish he has caught to his mate sitting in a nest scrape, below. The adult bird, right, is incubating a clutch of eggs at a nesting site on the coast of California.

each season, and in 1980 about 150 pairs nested in the fenced sanctuary, making it the largest in the state. An estimated 240 fledglings joined the migratory flock at the end of the season. The successful reestablishment of the Venice colony is an encouraging sign that there eventually may be California least terns nesting all along the coast on beaches from which they were extirpated.

Proper management of an endangered species must be based on a thorough knowledge of its life history. At the same time, the study of an endangered species must proceed with extreme caution in order not to jeopardize the subject one is trying to protect. Breeding California least terns do not tolerate more than a minimum amount of handling, and our research has been tailored to their needs. In 1976, we embarked on a long-term study based on color banding of chicks. The banding is done under the auspices of recovery team member Charles T. Collins, and my colleague on this project is Jon Atwood, a doctoral candidate in biology at UCLA. We have found that a group of three to five experienced people can move through a large colony in the early morning and collect growth data and color band about fifty chicks an hour, after which the colony is left to return to its daily routine. There have been no untoward effects from this procedure.

We have banded more than 2,000 chicks since 1976, and since 1978 have color coded youngsters so that many returning adults can be identified in the field as to age and natal colony. We now spend many hours during the nesting season in a blind looking for and trapping banded birds. The information being sought through banding includes age of first breeding, tenacity of the pair bond, duration of breeding life, intercolony movements, postseason wandering, and where the birds go for the winter. Data on returning birds are accumulating at an accelerated pace each year. We have learned that the terns begin breeding at the age of two; these young birds arrive on the nesting grounds about six weeks after the older, experienced breeders, and lay their eggs after the first wave of chicks has already hatched. None of the larger terns of the genus *Sterna* breeds regularly at such an early age, and this finding was quite unexpected. When the adults return for the first time to breed, they do not necessarily come back to their natal colony. Once they have bred successfully at a site, however, they show a marked tendency to return the following year.

Information on pair bonds is, at this stage, ambiguous. Pairs apparently remain together throughout a season, as evidenced by banded pairs renesting after the loss of eggs or chicks. But the tenacity of the pair bond from season to season varies. Some birds return annually to the same spot in a breeding colony with the same mate; others have returned to the same or a different colony with another mate. One pair of banded birds "divorced" after a year, and the following season each nested with a new mate within fifteen feet of its previous territory.

The question of where California least terns spend the winter is one of the most challenging aspects of our research.

When Jon Atwood and I organized a group to look for wintering areas in December 1978, our only sure knowledge was that the terns went south of the California border, as there were no wintering records in the United States. At that time there had been no banding recoveries outside the United States and we had no clues as to where to begin our search. (There has since been one recov-

Two- to three-day-old chicks are fed by their parents. Because the chicks have successfully hatched, the adult pair will return to the same nesting area next year, whether or not these young survive to fledge.

ery from Guatemala.) We decided to start at Guaymas on the northwest coast of mainland Mexico and work south, spot-checking estuaries all the way to Chiapas. On our first trip we saw no least terns at all. The following winter Alan Craig of California's Department of Fish and Game, and head of the recovery team, visited some of the areas we had not been able to cover and found a group of seventy-five least terns at an estuary in Colima, south of the city of Manzanillo. The terns, unfortunately, could not be approached closely enough for bands to be detected.

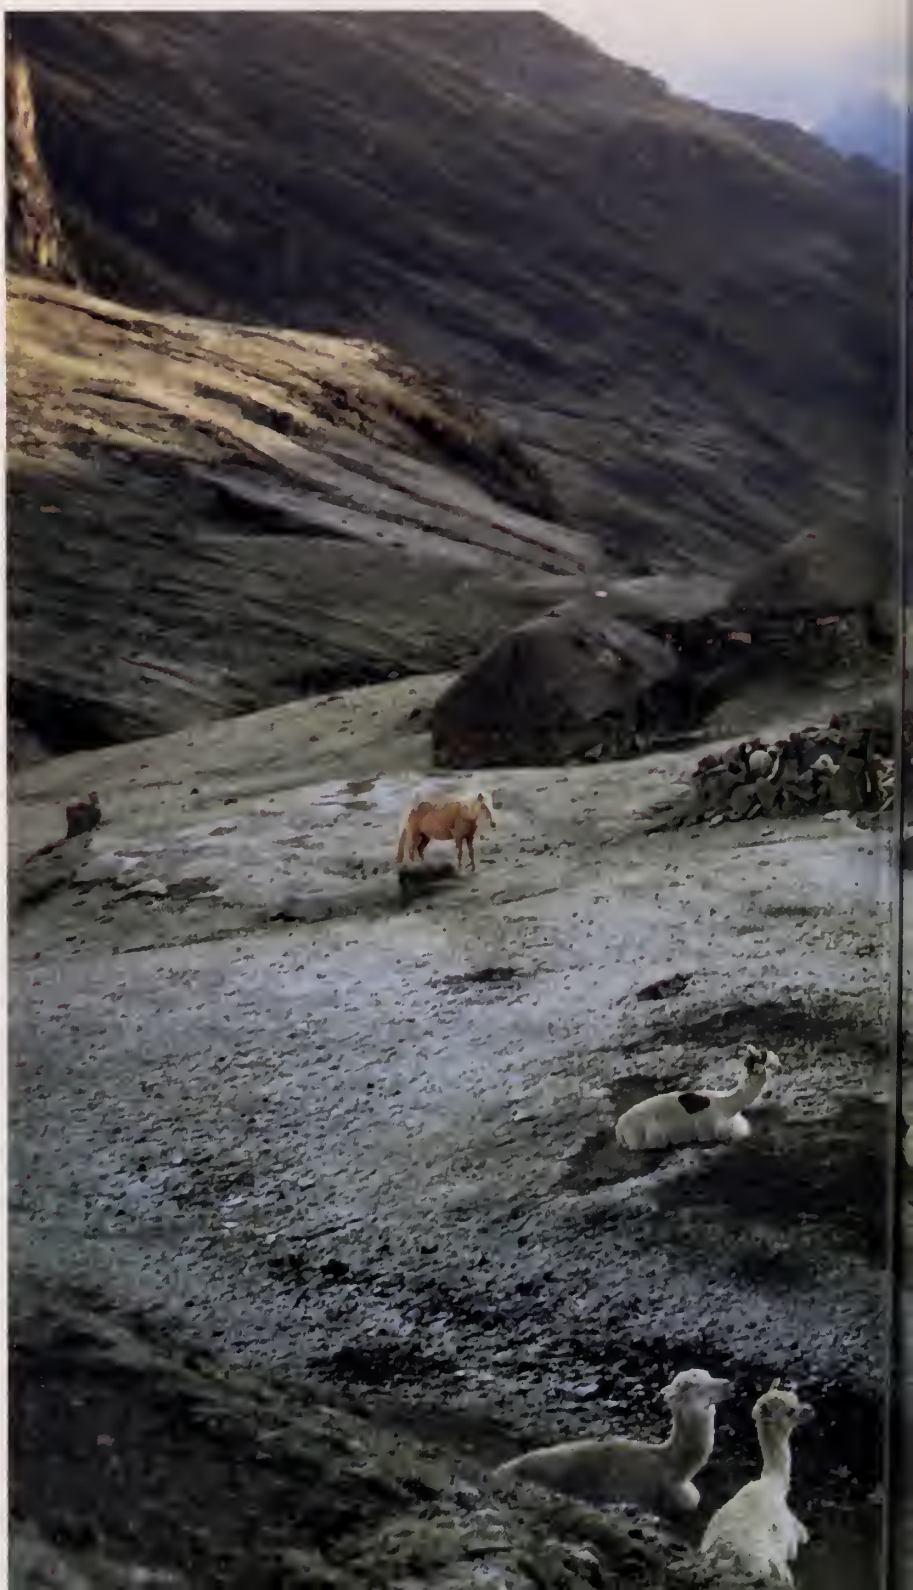
In January 1981 we headed south once again, this time to concentrate on the Colima coast. We found a small number of wintering least terns at three estuaries south of Manzanillo. Several of the birds were banded, and one memorable morning we saw a color-banded bird at Boca de Pescuales. It was identifiable, thanks to color coding, as a California least tern, banded as a chick at Huntington Beach State Park in Orange County in 1979.

Colima appears to be the northern limit of the birds' wintering range, but we have yet to identify the major wintering area, as we saw only twenty to thirty wintering least terns in Colima. Much of the coast of southern Mexico has not been searched, and the recovery of one bird from Guatemala suggests that the wintering range may extend south along the coast of Central America.

Our interest in finding the wintering grounds is more than academic. The birds are being protected in California during the nesting season, but two-thirds of their year is spent elsewhere, under conditions about which we know nothing. If we are to be effective in protecting this migratory bird, we must know its entire life history, not just the segment that takes place on our shores.

The goal of the recovery plan for the California least tern is to restore the breeding population to 1,200 pairs, or double the number in existence when the bird was first listed as endangered. With continued protection and the creation of additional nesting sites, that goal could be reached within five years. If at that time there are viable breeding colonies in at least twenty different coastal wetlands, all permanently protected, the birds' recovery will have been accomplished, and it can then be considered for removal from the endangered species list. That will be cause for celebration. □

Weathering Heights



People who live high in the Andes and Himalayas have adapted both culturally and biologically to their environment

by Charles A. Weitz

The special problems of life at high altitude have intrigued Westerners since at least the time of the Spanish conquest of the Incas. Throughout Francisco Pizarro's campaigns in the highlands, horses collapsed from exertion and soldiers suffered from mountain sickness. Later, Spanish colonists experienced altitude-induced infertility, and eventually, most Europeans settled in lowland areas near the coast. In recent years, biological anthropologists and environmental physiologists have studied the relatively large native populations that live above 10,000 feet in South America and Central Asia in order to learn how these people cope, culturally and biologically, with the stresses imposed by their environment.

There are three main forms of stress at high altitude: restricted food resources, cold, and—most severe of all—a reduction in the amount of oxygen reaching body tissues. This last phenomenon, called hypoxia, is caused by low atmospheric pressure, which unless compensated for, reduces the amount of oxygen that diffuses through the lungs and into the blood. When lowlanders journey to high-altitude areas, they frequently suffer from a variety of hypoxia symptoms, including headaches, nausea, fluid in the lungs, loss of appetite, fatigue, insomnia, and labored breathing. For most people, these problems are alleviated as their heart, lungs, and circulatory system adjust. But even the best-adjusted lowlanders rarely are able to duplicate the activity patterns of native highlanders. Since the basic cause of hypoxia cannot be attacked without sophisticated equipment, we may conclude that the nature of highlanders' superior adjustment to low atmospheric pressure is basically biological. Their adjustment to cold and nutritional stress, on the other hand, includes reliance on cultural means—learned behavior and technology.

All humans show some rapid biological responses to stressful conditions. In the cold, almost everyone will produce more body heat through shivering or an elevation in the basal metabolic rate.

Victor Englebert

In Queros, a Peruvian village east of the ancient Inca capital of Cuzco, Quechua-speaking Indians preserve a traditional style of life adapted to high altitudes. Like their rural counterparts in Nuñoa, a district south of Cuzco that has been intensively studied by physical anthropologists, these Indians herd llamas as a major means of subsistence. The piled stone houses protect the residents from rain and wind but provide only moderate protection from low nighttime temperatures during the cold, dry season.

Loren McIntyre, CHER Agency

Increases in breathing and heart rates and red blood cell numbers are adjustments that most low-altitude residents make after arriving at high altitude. These short-term physiological responses are fairly easy to identify. The issue biological anthropologists have found more intriguing is whether the physiological and morphological characteristics of highlanders that lowlanders are unable to duplicate are the result of gradual adjustments that accumulate during the developmental years or the result of unique genetic adaptations to high altitude.

According to the best estimates, between fifteen and twenty million people live above 10,000 feet in the Andes and on the Andean *altiplano* ("high plateau"), and another three to five million live above 10,000 feet in the Himalayas and on the Tibetan plateau. While a number of good cultural and biological studies have been carried out in both these areas, the greatest amount of data is available for two groups: the 8,000 or so Quechua Indians who live on the *altiplano* in the Nuñoa district of southern Peru, and the approximately 2,500 Sherpas who inhabit the Khumbu region of eastern Nepal. The Sherpas do not actually live on the Tibetan plateau, but just south of it in the high alpine valleys of the Himalayas. Still, the Sherpas are a Tibetan-derived group that possesses many features of the larger Tibetan culture, which has not been accessible for systematic biological or cultural investigation. Information on Nuñoa comes from a large and well-integrated project initiated and, for the most part, directed by Paul T. Baker of Pennsylvania State University. Information on the Khumbu has not been collected as systematically, but taken as a whole forms a meaningful counterpart to the Nuñoan data.

As their names suggest, both the Andean *altiplano* and the Tibetan plateau are relatively flat landscapes, consisting mainly of valleys separated by rolling hills. The floors of the valleys range from 10,000 to 15,000 feet; the hills are about 1,000 feet higher. The Andean *altiplano* is rimmed by the high Andes to the east, while the Tibetan plateau is rimmed by the Himalayas to the south. These mountain ranges act as moisture barriers, preventing most of the rainfall that makes South Asia and the Amazon so lush from penetrating the high-altitude plateaus.

The Andean *altiplano* and the Tibetan plateau are cold, but not frigid, areas. Nuñoa falls within the tropical zone south of the Equator, where seasonal changes are not pronounced. Daily maximum temperatures remain consistently comfortable throughout the year: between 61° and 66°F. Nighttime temperatures, on the other hand, do show some seasonal variation and can be quite cold: average lows range from about 37° during the rainy months of April through September to 14° during the dry months of October through March. Snow is uncommon, and when it does occur, it is light and quickly melted by the warm daytime temperatures. The Khumbu region of Nepal is located in the Northern Hemisphere's temperate zone, at roughly the same latitude as Tampa, Florida. This position produces marked seasonality: in Khumbu villages between 11,000 and 12,000 feet, the average daytime maximum temperatures range from 39° during January to 64° in July; average nighttime minimum temperatures range from 14° in January to 50° in July. Winter conditions are made even more severe by periodic snowfalls. With clothing, housing, and other means, however, both the Quechuas and the Sherpas are able to modify their immediate environments to reduce cold stress significantly.

Domesticated in the New World, the potato can be cultivated successfully in high-altitude areas; it is the staple crop in both the Andes and the Khumbu. Left: Quechua women near Cuzco apply guano to green potato plants, four months after planting. Below: Sherpa women and lowland helpers plant potatoes in a Khumbu village.

Robert Weinreb

In Nuñoa and the surrounding area, considerable research has been carried out on the natural cold stress endured by the inhabitants, as well as the biological and cultural adjustments to cold stress. Most of this research has been directed by Michael A. Little of the State University of New York at Binghamton, J. Michael Hanna of the University of Hawaii, and Paul T. Baker. One finding is that on the *altiplano*, clothing offers considerable protection against heat loss.

Quechua men's underwear consists of long pants and a long-sleeved shirt. Over these are worn homemade pants and a shirt, covered by a vest and jacket. During early morning and late evening hours, when it is quite cold, men will wear heavy woolen ponchos and knitted stocking caps with earflaps. Quechua women wear several woolen mid-calf-length skirts, a blouse, a jacket, and a shawl. Mittens are rarely worn by either sex, but hands can be placed underneath clothing to be warmed. Normally, adults go barefoot or wear sandals with soles made from pieces of rubber tires. This type of clothing is remarkably effective in protecting adults against the cold. In the dry season, average skin temperatures are consistently 90°, despite an ambient temperature that fluctuates between 21° and 68°. In the wet season, hands and feet undergo greater stress but remain at temperatures of at least 74°. Perhaps the greatest exposure to cold occurs when adults must work in water, for example, washing clothes or building channels. Under these circumstances, foot and hand temperatures may fall below 59°. (Although it may cause some discomfort and reduced function, this temperature is not low enough to damage tissues in the short run. Of course, prolonged exposure can lead to a dangerous loss of internal heat.)

Children five years of age and older wear the same sort of clothing as adults and are perhaps the most subject to cold stress. But even out of doors during the wet season, toe and finger temperatures of Quechua children remain above 68°.

Infants are well protected. They are usually diapered and wear an undershirt, a homespun tunic, one or more sweaters, and a knitted hat. Nursing and changing are done near a fire, and the infant usually plays in the sunniest area near the house.

Urban houses in Nuñoa are constructed of adobe and covered with mud or plaster stucco, while rural houses are made with piled stone walls and thatched roofing. During the cold, dry season, nighttime temperatures inside adobe houses average 45°, while outdoor temperatures are well below freezing. Rural houses offer considerably less protection against the wind and cold. At night, the average difference between minimum indoor and outdoor temperatures is less than seven degrees, so that indoor temperatures fall below freezing during the cold, dry season.

During sleep, people in Nuñoa protect themselves from the cold in two ways. First, the family members usually sleep together under blankets, sharing body heat; and second, most people sleep with their clothing on. In rural areas during the cold, dry season, this type of sleeping arrangement is associated with only slight reductions in adults' body temperatures. Somewhat greater reductions occur in children's body temperatures, but these effects are not great enough to be harmful.

Despite their cultural adaptations, the Quechuas are more exposed to cold than their lowland neighbors, and therefore, they differ from nonstressed lowlanders in their biological response to cold. Like the Eskimos, Quechua adults have a slightly elevated basal metabolic rate, permitting them to maintain higher than normal internal temperatures while sustaining the peripheral blood flow necessary to warm their extremities; this is probably why the skin temperatures of their hands and feet remain high enough to prevent tissue damage even though mittens and shoes are rarely worn.

Body size and physique are also important in determining the biological response to cold. Although shorter than people in the United States, Quechuas are more stockily built. Their shorter arms and legs reduce the skin surface area relative to body weight, helping to lower heat loss and to maintain normal internal body temperatures.

In all populations, men, women, and children differ in their response to cold. Women have a larger proportion of body fat, which acts as insulation. Que-

Below: A Quechua agriculturist near Cuzco carries a bundle of cornstalks to a Sunday market. Right: A Quechua girl from the Huayhuash Mountains northeast of Lima is protected from the cold by layers of clothing. The style and abundance of her clothing and her Western shoes suggest that she is the child of an upwardly mobile Indian family.

Loren McIntyre, CHER Agency

chua women have a slightly higher internal temperature than Quechua men and therefore are probably more resistant to cold. Children, who have lower amounts of body fat and large skin surface areas relative to their body weight, are more prone to lose heat and have lower internal and skin temperatures. Consequently, Quechua children are more likely to experience cold stress than adults.

Among the Quechuas, physiological responses to cold seem to develop gradually throughout childhood. This occurs not only because of the morphological changes associated with growth but also because repeated exposure to cold may prime certain physiological responses, such as an elevated metabolic rate.

Biological adjustments to low temperatures have not yet been investigated among the Khumbu Sherpas, but the overall conclusion would probably be the same as for the Quechuas, namely, that the problem of cold stress at high altitude has been overcome to a great extent through cultural adaptation.

For the Sherpas, the need for protection is greatest during the winter months, when both daytime and nighttime temperatures are low. Traditionally Sherpas have relied upon thick clothing made from yak or sheep wool. Over their full-length undergarments, women wear full-length woolen *chubas*, or jumpers, which have flaps at the sides that can be wrapped around the back. In addition, a broad cummerbund is used to hold a brightly colored apron over the front of the skirt and, in colder weather, a heavy cloth draped around the back of the skirt. Women also wear several blouses: underblouses are made of soft cotton, while outer blouses, particularly in the winter, are made of coarse, heavy cotton. Men wear heavy woolen pants and layers of shirts, covered by vests or sweaters. A knee-length woolen coat, or *bakhu*, can be worn with both arms through the long sleeves, with only one arm through one of the sleeves, or with both sleeves wrapped around the waist. In winter, most men wear thick sheepskin coats while herding yaks or doing other work in the open. Traditionally, both sexes wore leather-soled boots, with layers of matted wool to provide insulation and cushion the feet and uppers of heavy wool that lace up the back. Men and women also wear fur-lined hats with flaps that can be pulled down over the ears.

Children, after they are about four years old, wear smaller versions of adult clothing. Infants are generally warmly swaddled in several blankets, and mothers take care to avoid exposing them to cold. They are cleaned only with warmed oils and are never changed or unswaddled away from a heat source. Toddlers frequently wear quilted coveralls with a slit in the crotch so that they can urinate or defecate without soiling their clothes. For the last fifteen to twenty years, most Sherpa children have worn Western shoes and socks, although some families still prefer the traditional boot. Neither children nor adults generally wear gloves or mittens while doing traditional chores, but most adult clothing has sufficient folds to protect hands against the cold. Toddlers' clothing does not have this advantage, and the lack of hand protection may be a source of cold stress.

Sherpa houses are built with thick stone and mortar walls that provide protection from the wind, particularly since windows are few and generally placed on only one side of the house. Most houses consist of two stories: the ground floor is used as a manger and storage area, and the family lives in one large room above. The manger may provide some heat for the upstairs, but the second-story room is so large that much of the benefit is lost. Sherpa houses have peaked roofs constructed of timber beams. These are covered by mats or by pieces of slate. The upstairs room may be thirty or even forty feet long and half as wide. A small fire, located toward one end of this room, is lit at mealtimes and, during the winter, may be kept going all the time. During the night, this part of the room will remain up to 12 degrees warmer than the minimum outdoor temperature even if the fire is allowed to go out. Away from the fire, the room temperature falls to only 4 or 5 degrees warmer than minimum outdoor temperatures. Sleeping arrangements vary: in some houses, beds are located near the fire, while in others, they are in the coldest part of the room or along the walls. Families with small children tend to sleep huddled together, covered by thick blankets. Older children may sleep

In the Khumbu region of Nepal a Sherpa girl herds goats past Tamang porters from the lowlands to the south, carrying rice and sugar to a weekly market. In both the Himalayas and the Andes, resources available at different altitudes are exchanged between neighboring populations.

separately and thus are more apt to be affected by the cold.

Sherpa adults probably experience the greatest cold stress in winter, when animals must be herded from high pastures to lower ones. The amount of activity involved is so great, however, that it surely must provide some metabolic compensation. In addition, prodigious amounts of Tibetan tea (tea and butter with a little salt) or tea with milk and sugar are consumed by everyone. Since drinking hot beverages elevates internal temperatures, this probably provides additional fortification against the cold.

Mountaineering, trekking, and a growing cash economy have changed Sherpa conditions somewhat during the last decade. Men tend to wear Western mountaineering dress, which is designed to maximize protection against the cold. But mountaineering expeditions now expose Sherpa men to high mountain areas that are far colder than their normal habitation zone. And because Tibetan yak wool is becoming difficult to obtain, Sherpa women now often wear *chubas* of heavy cotton, which probably offer less protection against the cold. On the other hand, the recent introduction of kerosene space heaters—and possible future availability of electric heaters—may reduce cold stress considerably.

In addition to cold, a high-altitude population must cope with marginal nutrition. In part, poor nutrition may be attributed to cultural values concerning food selection, preparation, and distribution. Nevertheless, high-altitude environments such as those of Nuñoa and Khumbu do limit the quantity and quality of food crops, just as they limit other types of vegetation. In both areas, the soils tend to be poor. Of equal importance are the hazards of low temperatures, frosts or snowfalls, and unreliable precipitation during the crop-growing season. The last is a particular problem on the *altiplano*, since planting is done during September and October when precipitation is very erratic. In the Khumbu region, dews and fogs provide moisture in the absence of heavy rainfalls.

In both Nuñoa and Khumbu, diets consist primarily of vegetable foods. Most common in Nuñoa are potatoes and Andean grains, along with rice and maize (mostly imported from other areas). Depending upon the success of the harvest, potatoes contribute up to 48 percent of the diet. Only 6 to 17 percent of the food consumed by the Quechuas derives from animal sources. Still, protein consumption in Nuñoa seems adequate, except for children under three and girls from nine to twelve. Caloric intake, on the other hand, is highly variable and may not be adequate during childhood years or during periods of physiological stress, such as pregnancy or lactation.

In Nuñoa, R. Brook Thomas of the University of Massachusetts has identified four behavioral adjustments to the low caloric potential of the environment. First, the Quechuas depend upon a mixed and spatially dispersed resource base consisting of both crops and animals that are well adapted to the environment and produce the most calories for the least amount of work. Second,

surplus resources (mostly animal products) are sold and exchanged for calorie-rich products from other areas. Third, children, who consume the least numbers of calories regardless of the undertaking, are often assigned active tasks, such as herding, that would be calorically more costly for adults. Fourth, the tasks necessary for subsistence are organized so that large amounts of time can be spent in sedentary or near-sedentary activities. Even in herding, up to three-quarters of the time may be spent in a stationary position.

The potato, which was originally domesticated in the Andes, also became the staple among the Sherpas during the late nineteenth century. It constitutes from 30 to 44 percent of the adult diet. The rest is made up of cereals, such as buckwheat and millet, mustard greens in summer, Tibetan tea, and considerable amounts of rice or millet beer called *chang*. About 80 percent of this diet is carbohydrates, and what protein there is comes mostly from vegetable sources. The result is a diet that tends to be calorically adequate but deficient in protein. Compared to the Quechuas, however, the Sherpas are more active and probably have greater caloric requirements. Herding entails continuous flanking movements on the steep mountain slopes to keep the skittish cattle from straying. In the past, long-distance trade meant journeys by foot over steep mountain passes, and at one time, teams of men were used to pull the plows that tilled the soil for buckwheat and barley. Today, mountaineering and trekking tax the strength and endurance of both men and women.

One biological consequence of inadequate caloric or protein intake is growth retardation. Among both the Quechuas and the Sherpas, physical growth is much slower than among people in the United States. Skeletal growth and mineralization are slow, the growth spurt during adolescence is retarded, and maturation is delayed until the early to mid-twenties. Far from being maladaptive, however, retarded growth and small body size can add up to a caloric saving. Thomas has estimated that for the Quechuas, the retarded growth at adolescence alone (between the ages of fifteen and twenty) saves an average of 121 calories per day, or more than 44,000 calories per year. This saving is equivalent to planting an additional 100 square yards of cropland for each adolescent every year.

Unfortunately, it is extremely difficult to tell how much of the retardation

The Loch Lomond Monster. You'll Find Proof He Exists.

Loch Ness has a nice shy monster. It bothers no one and makes no noise.

Loch Lomond has a totally different kind of monster. The men in our blending room, near Loch Lomond, see him regularly. His fearful bellows fill the air until he gets just what he wants.

His name is George Shortreed. He searches all of Scotland to find whiskies noble enough to blend with those of our very own Speyside distilleries. His knowledge and his will are what make J&B so well respected.

His stubborn, unswerving goal is to create a taste so smooth, so subtle we can say it whispers. And he'll be as harsh as he has to, to be sure J&B never is.

The men who work for him call him the Loch Lomond monster. But never when he can hear.

When George Shortreed is around, the men speak in hushed tones, and the whisky whispers.

J&B. It whispers.

Journey through Moroccan cities and countryside to visit the famous medieval city of Fes, the souks of Marrakech, and camel markets at Rissani, the Atlas Mountains and the Sahara Desert. Visits to Berber villages; archeological sites and museums in Tangier, Rabat, Roman Volubilis and Lixus. Tour is led by Paul J. Sanfacon, Lecturer in Anthropology at the Museum. Limited to 20 participants. For further information write to DISCOVERY TOURS, American Museum of Natural History, Central Park West at 79 St., NY NY 10024, or call (212) 873-1440.

Speak German like a Diplomat!

What sort of people need to learn a foreign language as quickly and effectively as possible? Foreign service personnel, that's who.

Now *you* can make a start on learning to speak German with the same materials used by the U.S. Department of State — the Foreign Service Institute's *Programmed Introduction to German* and *Basic Course, Continued*.

The FSI spent thousands of dollars and many years developing these materials for use by members of America's diplomatic corps. Today people in all walks of life who need to learn to speak a foreign language are turning to this outstanding audio cassette program.

The Foreign Service Institute's German Course is by far the most effective way to learn German at your convenience and at your own pace. It consists of a series of tape cassettes and accompanying textbook. You simply follow the spoken and written instructions, listening and learning. By the end of the course you'll find yourself learning and speaking entirely in German! A native German speaker, clearly recorded on the cassettes, provides an excellent model to help you develop your skills.

This course turns your cassette player into a "teaching machine." With its unique "programmed" learning method, you set your own pace testing yourself, correcting errors, reinforcing accurate responses.

The FSI's Programmed German Course comes in two volumes. You may order one or both courses

☐ **Volume I. Programmed introduction to German,** 9 cassettes, 12 hours and 647-page text, $115.

☐ **Volume II. Basic Course, Continued** 8 cassettes, 8½ hours and a 333-page text, $98

(Connecticut residents add sales tax.)

Your cassettes are shipped to you in handsome library binders.

TO ORDER, JUST CLIP THIS AD and mail with your name and address, and a check or money order. Or charge to your credit card (American Express, VISA, Master Charge, Diners Club) by enclosing card number, expiration date, and your signature.

The Foreign Service Institute's German course is uncondltionally guaranteed. Try it for three weeks. If you're not convinced it's the most convenient and most painless way to learn German, return it and we'll refund every penny you paid! Order today!

in the rate of growth is a response to poor nutrition and how much is a response to hypoxia, the third and most severe source of stress in high-altitude areas. Most experts on the growth of Andean natives, such as A. Roberto Frisancho and Jere D. Haas, feel that both hypoxia and poor nutrition are implicated but tend to emphasize the former. The Andean data also suggest that slow growth is a developmental, not a genetic, response to high-altitude conditions. On the other hand, I.G. Pawson has concluded that slow Sherpa and Tibetan growth may be programmed genetically.

Because of hypoxia's severity, one might expect the cardiovascular and pulmonary responses of all high-altitude populations to be the same. Intriguingly, however, the Quechuas of the *altiplano* and the Sherpas of Khumbu may not possess the same kinds of adjustments. The best way to understand the characteristics of the two is to follow the pathway of oxygen from the air breathed by the lungs through the circulatory system to the active tissues.

The diffusion of oxygen from the lungs into the blood is affected by the size of the lung surface, the amount of air that is moved into and out of the lungs per minute, the amount of blood that passes through the lungs, and the speed at which it does so. Research in Nuñoa and elsewhere in the *altiplano* has revealed that the chest sizes of Quechua children and adults are larger than those of people in the United States, even though Andean natives are physically much smaller. This feature has been linked to their large lung volumes. On the other hand, the Sherpas have smaller chests than Quechuas of similar age, and adult lung volumes are far lower. The larger lungs of Andean natives indicate a greater surface area for the diffusion of oxygen into the blood.

Another factor affecting diffusion is ventilation—the amount of air that is moved into and out of the lungs per minute. For both Quechuas and Sherpas, ventilation is greater than for lowlanders tested at sea level. Among both groups of highlanders, however, sensitivity to low levels of oxygen in the blood is reduced, so that hypoxia-induced hyperventilation—so common among lowlanders tested at high altitudes—does not occur. This so-called blunted hypoxic drive may prevent a dangerous fall in the level of carbon dioxide in the blood, which normally accompanies hyperventilation.

Among lowlanders who remain a

week or more at high altitude, the number of red blood cells can increase by up to 50 percent, depending on the altitude and the length of time spent there. Since hemoglobin is the major transporter of oxygen in the blood, an increase in the number of red blood cells has generally been interpreted as a means of increasing hemoglobin and getting more oxygen to the tissues. Among *altiplano* natives, however, evidence for increases in red blood cell number has been variable. At extremely high altitudes (14,700 feet and above), red blood cell counts 50 to 60 percent above sea-level norms have been reported, while among Quechuas tested at Nuñoa, red blood cell counts are reported to be only about 10 to 12 percent above sea-level norms. By contrast, red blood cell counts of Sherpa adults and children are considerably lower, actually in the low end of the normal range for sea-level populations.

As oxygenated blood circulates through the body, the oxygen is released for use in the tissues. The unbinding, or dissociation, of oxygen from hemoglobin is enhanced among the Quechuas because at high altitudes more CO_2 is picked up by hemoglobin as red blood cells pass through the capillaries. As this happens, hemoglobin's affinity for oxygen is reduced, and more oxygen can be released to the tissues. Travelers to high altitudes and Andean natives also show an increase in their blood of a compound called 2,3 diphosphoglycerate, which has the effect of increasing the amount of oxygen released to the tissues. When oxygen concentrations are low, as in the capillaries, the 2,3 diphosphoglycerate reacts with hemoglobin, interfering with hemoglobin's affinity for oxygen. Together with an increase in the size and number of capillaries perfusing the active tissues, these characteristics insure delivery of sufficient oxygen to the tissues.

Unlike the Quechuas, Sherpas may not have increased levels of 2,3 diphosphoglycerate—at least at altitudes below 14,000 feet. Since they also do not exhibit large lung capacities or elevated red blood cell numbers, the question is, what sort of adaptation do they have? Unfortunately, the answer is not yet clear. Some data seem to show a slightly lower carbon dioxide concentration in the lungs, perhaps indicating a slightly higher ventilation. It is also possible, according to one study, that the affinity between oxygen and hemoglobin is greater for the Sherpas than for the Quechuas. But Sherpas don't appear to possess any special type of hemoglobin,

An elegant, provocative exploration of the ways "science" has attempted to rank people

"A brilliant book....The lombrosos, Hootons, Goddards, IQ testers, racists, and others of their kind, are literally taken to pieces by Gould in a book that is as important as it is readable. ...Of no book could it be more sincerely said that it deserves to be widely read."

and oxygen saturation in their blood is about the same as that of the Quechuas. Perhaps the answer lies in the way oxygen diffuses across the pulmonary membrane. Whatever the adjustments may prove to be, they must be remarkably effective. Sherpas are renowned for their ability to carry heavy loads (as much as sixty pounds, or half their body weight) at altitudes up to 23,000 feet. Furthermore, I found that their maximum oxygen consumption equaled that of the Quechuas and was similar to levels achieved by highly active lowlanders tested at sea level.

We are now fairly certain that many of the Andean adjustments to high-altitude hypoxia are not genetic. A. Roberto Frisancho has demonstrated that nonnative children who migrate from sea level to high altitudes and remain there while growing up eventually attain the same lung volumes as high-altitude natives. Sukhamy Lahiri of the University of Pennsylvania School of Medicine has also reported that neonates and infants have the same lung volumes at high and low altitudes, but that a difference appears by adolescence. The large lung volumes of Andean natives seem, therefore, to be a developmental response. In addition, Lahiri has shown that the "blunted" ventilatory response to hypoxia only begins to manifest itself during adolescence and becomes irreversible by adulthood. Again, this is strong evidence that the ventilatory rate of Andean natives is developmentally determined. Finally, Frisancho has noted that the maximum amount of oxygen that can be delivered to the tissues during exhausting work is also affected by age at migration. The younger the age at migration and the longer the stay at high altitude, the greater the maximum oxygen consumption. These findings do not rule out the possibility of genetic adaptations but, as yet, no such adaptations are apparent.

Having considered some of the ways in which Quechuas and Sherpas have adapted, culturally and biologically, to living at high altitude, it may be appropriate to conclude by evaluating the degree to which environmental stress nevertheless takes its toll among these people. The impact of altitude on survival begins even before birth. Because of the low amount of oxygen that diffuses across the placental membrane into the fetal system, all fetuses (even those at low altitude) develop in an hypoxic environment. Atmospheric hypoxia may create an additional stress for high-altitude fetuses, despite their mothers' physiological adjustments. Perhaps to maximize the amount of oxygen available to the fetus, the placentas of *altiplano* women are larger in diameter, thinner, and weigh more relative to fetal weight than is the case at low altitude. Nonetheless, both fertility and birth weight appear to be lower at high altitudes.

Although reduced, fertility in the *altiplano* is still high. Completed family size (the total number of live births to women age 45 and over) averages 6.7 in Nuñoa and is similar in other areas of the *altiplano*. In comparison, completed family size in one well-studied area of low-altitude Peru was 8.3.

Sherpa fertility is much lower—completed family size is about 5.1. Part of the difference may be explained by various cultural factors that seem to lower Sherpa fertility. In the past, low iodine intake caused a significant proportion of the Khumbu population to suffer from hypothyroidism, which is known to result in an extremely high level of spontaneous abortions.

Low birth weight also seems to be a consequence of gestation at high altitude. Jere D. Haas reports that children born of Quechua mothers at high altitude weigh about three-and-one-half ounces less than children born to Quechua women at low altitude. And children born to non-Indian women at high altitude weigh more than a pound less than those born at low altitude. Fewer data are available for the Sherpas, but nineteen neonates weighed by physicians at the Kunde hospital between 1967 and 1972 were, on the average, nearly one-half pound lighter than high-altitude Quechua neonates. The reduction in birth weight is important because it is associated with inadequate respiratory function, poor temperature regulation, poor resistance to infection, a high incidence of anemia, and inadequate renal function. Despite the apparent differences in birth weights, the *altiplano* and the Khumbu region have equally high infant mortality rates: between 150 and 160 per 1,000 live births (about twelve times the U.S. rate).

To a certain extent, these rates are the result of diseases (such as gastrointestinal disorders) that cause high infant mortality regardless of altitude. But others, particularly respiratory diseases, are more common causes of death at high altitude. Some studies show that the effect of altitude on infant mortality may be especially strong immediately following birth. In both Peru and the United States, deaths during the first

AMERICA'S TRUCK, BUILT FORD TOUGH.

LION IN WINTER.

Bronco roars to the top nonstop. Its husky 4.9L (300) Six churns out more torque than any competitive Six. It also turns out excellent gas mileage ratings: 24 est. highway, ⑰ EPA est. mpg.*

Inside it's a real family 4-wheeler. There's room for six with front and rear bench seat options (front buckets are standard). But Bronco's trim outer size makes it easy to maneuver, fun to drive *wherever* you drive.

Underneath you'll find the only independent front suspension in an American-built sport utility. It's smooth *and* tough!

Mileage-boosting 4-speed overdrive, another Ford first, is optional. So are automatic locking hubs. They run free on the highway, lock in automatically when you shift to 4WD.

No other 4-wheeler offers all this. So why settle for less than Bronco—it's one beautiful beast!

* 4.9L Six and optional overdrive. Use for comparison. Your mileage may differ depending on speed, distance and weather. Actual highway mileage lower. California ratings less, V-8 required.

In a teashop in the Takshindu Pass, on the route to Mount Everest, a Sherpa nun makes rakshi, *a liquor distilled from grain or potatoes. The teashop, on the grounds of a Buddhist monastery, earns money by providing overnight lodging for porters and Western travelers.*

month after birth are more frequent at higher elevations. This may partly explain why, in the late 1960s and early 1970s, infant mortality in the Khumbu and in Nuñoa was between 15 and 20 percent higher than for Nepal and Peru as wholes.

Throughout childhood and adulthood, both Sherpas and Quechuas are plagued by respiratory diseases. They are the major cause of death at all ages in the *altiplano* and the most frequent diagnosis made by physicians at the Kunde hospital in Khumbu. Second in importance are gastrointestinal disorders. In both areas, uncontrolled diarrheas are a common cause of infant and early childhood mortality. One bright feature in the health picture is the absence of cardiovascular diseases. Blood pressures in both groups are low by U.S. standards, and do not appear to increase significantly with age.

In both groups, hypoxia, poor nutrition, disease, and physical trauma combine to significantly reduce survivorship. Only about 65 percent of the Sherpas survive to adolescence, and the rate is roughly the same for the Quechuas in Nuñoa. For those Quechuas who survive past age fifteen, the average age at death is about forty-nine-and-one-half years for pastoralists and about fifty-five years for nonpastoralists. The Sherpas' average life expectancy at age fifteen appears to be between forty-eight and fifty years.

A short life is not unique to these two high-altitude populations. Among many lowlanders, particularly in developing countries, life expectancy is equally short. But the reasons for death may be quite different. At high altitude, respiratory and some infectious diseases seem to be more common, and it is possible that high-altitude Peruvians suffer from an increased level of congenital heart defects. On the other hand, some particularly devastating low-altitude diseases rarely penetrate to high-altitude areas. This is the case for malaria—one of the major causes of death worldwide—because environmental conditions prevent the spread of the disease-bearing mosquito to high altitudes.

There is no doubt that both the Sherpas and the Quechuas have made physiological and morphological adjustments to high altitude that help them to exploit their limited environment. Even in conjunction with important cultural adaptations, however, the biological adjustments cannot completely protect these people from the stress of their environment. The consequence—contrary to some popular assumptions concerning unusual longevity and good health among high-altitude populations—is lowered fertility, a prevalence of respiratory disease, and death at a fairly early age. □

AMERICAN MUSEUM OF NATURAL HISTORY
Vacations on sea and land with Museum Lecturers

NILE CRUISE: Explore the astounding ancient sites and natural wonders of Egypt with a Museum geologist, ornithologist illustrator, and Egyptologist. Cruise 600 miles on the Nile from Cairo to Assuan aboard the custom-built, air-conditioned *Nile Star* stopping at all the important sites which have intrigued visitors since their construction.

INDONESIAN ODYSSEY: Cruise through the paradise islands of Bali, Java, Komodo, Sulawesi, Lombok, Flores, Butung, the Moluccas and Luciparas aboard the luxury vessel, *Regina Maris*. Share with a Museum astronomer, anthropologist, ornithologist, geologist volcanologist, and herpetologist a unique, in-depth travel experience. The itinerary takes you to lush tropical landscapes with exotic peoples influenced for centuries by India, Islam and Europe.

GALAPAGOS ISLANDS CRUISE: Discover a special natural world with fantastically tame and exotic animals such as sea lions, giant tortoises, marine and land iguanas and countless rare and beautiful birds. Enjoy the expertise of a Museum ornithologist and herpetologist and four local naturalists as we cruise through this equatorial archipelago which so influenced Darwin.

ADRIATIC AND AEGEAN ADVENTURE: Relive the great historical travels of the Greeks, Romans, Phoenicians and Venetians. Follow their paths on a classical cruise starting in Venice and going to Dubrovnik, Corfu, Corinth, Crete, Rhodes, Tunis, Carthage, Malta, Sicily, Pompeii, Herculaneum and Naples. The *Orpheus* will be your home for 14 beautiful days; the Museum faculty will be outstanding.

LAND PROGRAMS: Seven outstanding overland itineraries have been custom-designed for small groups of 15-25 participants. Famous and remote sites and cultures are discovered while staying at the finest accommodations available with expert Museum Lecturers.

DISCOVERY TOUR TO THE NILE

American Museum of Natural History
Discovery Tours

Discover the world of ancient and modern Egypt on an American Museum 600 mile Nile Cruise. Explore with three lecturers the rich natural and archeological sites of an area which has fascinated visitors for centuries... A carefully planned itinerary (with a special two-day program in London visiting the British Museum with its keeper) provides a relaxing and thorough three-week Discovery Tour. All of the major Nile archeological sites as well as the important wildlife regions are discussed and visited with your balanced team of eminent lecturers. Share with Museum staff and friends an unforgettable cruise. February 7-27, 1982. For further information and itineraries write to the **American Museum of Natural History, Discovery Tours,** Central Park West at 79 St., NY NY 10024, or call (212) 873-1440.

Snowshoe Hares (p. 46)

W.B. Grange's *The Way to Game Abundance* (New York: Charles Scribner's Sons, 1949) is a thorough treatment of the subject of game management, emphasizing the need to match control strategies with an animal's life patterns and environmental interactions. Part of the section on population cycles is devoted to the snowshoe hare, outlining the mechanism and simultaneity of its cycle, the changes in its habits and psychology, and the nature of predation. L.B. Keith's *Wildlife's Ten Year Cycle* (Madison: University of Wisconsin Press, 1963) presents information on the ten-year cycle, a phenomenon of long-term fluctuations in northern wildlife populations, and systematically reviews what is known about these fluctuations—their periodicity, regularity, amplitude, and synchrony; relationship to other population phenomena; and postulated causes. Extensive data on the snowshoe hare, dating from 1849, are analyzed and interpreted. G.E. Hutchinson's *An Introduction to Population Ecology* (New Haven: Yale University Press, 1978) is a comprehensive, readable introduction to the interrelationships in nature that determine ecological balance and explain behavior. Although the author uses mathematics to explain his subject, it is kept to a minimum and is, for the most part, simple. *Stability and Complexity in Model Ecosystems*, edited by R. May (Princeton: Princeton University Press, 1974), illustrates various hypothesized relationships in nature through the use of ecosystem models. The book is clearly written but it demands a knowledge of statistics, matrix algebra, and differential calculus. J. P. Finerty's *The Population Ecology of Cycles in Small Mammals* (New Haven: Yale University Press, 1980) takes a look at all the different hypotheses of animal cycles, particularly the well-documented snowshoe hare cycle. The first section is a natural history of lemming, vole, and hare cycles; the book later involves fairly high-level mathematics. D.H. Janzen's "New Horizons in the Biology of

Additional Reading

Plant Defense" (in *Herbivores: Their Interactions with Secondary Plant Metabolites*, edited by G.A. Rosenthal and D.H. Janzen, New York: Academic Press, 1979, pp. 331–50) is a general outline of plant–herbivore interactions, presenting data on plant-induced mechanisms. Also readable, although written in a technical format, is E. Haukioja's "On the Role of Plant Defenses in Herbivore Population Fluctuations" (*Oikos*, vol. 35, pp. 202–12).

Great Plains (p. 54)

Historian W.P. Webb's classic history *The Great Plains* (Lincoln: University of Nebraska Press, 1981, $9.95), originally published in 1931, has recently been reissued in paperback. Webb's account of the interactions between the central plains and the people who settled it includes physical description, history, anthropology, literature, and economics. *Love Song to the Plains* (Lincoln: University of Nebraska Press, 1966, $3.50 in paperback) is M. Sandoz's lyrical salute to the area and the different types of people who became plainsmen. G. Hyde spent thirty years studying the Pawnee, the Plains tribe whose territory once spanned from Nebraska to Mexico. His 372-page assessment of the tribe, its culture, religion, and political organization is *The Pawnee Indians* (Norman: University of Oklahoma Press, 1974). P. Farb's *Face of North America*, with illustrations by J. Connolly (New York: Harper and Row, 1963), is a well-written, standard natural history of the continent, with a section devoted to the Plains.

Terns (p. 62)

Two popular books on terns are M. Harwood's *The View from Great Gull* (New York: E.P. Dutton, 1976), about terns on Long Island, New York, and J. Hay's *The Spirit of Survival* (New York: E.P. Dutton, 1974), a natural and personal history of the common tern. Both are easy to read and accurate. A classic study on which most recent work is based is R.S. Palmer's *A Behavior Study of the Common Tern* (*Proceed-*

The Aviator Shirt.

Authentic. Manufactured by Van Heusen—the people who supply most of America's leading airlines. Features button-through flap pockets, one with pencil slot. And epaulets, naturally. Collar looks neat and correct worn open or with tie. Extra-long tail. This special edition Van Heusen shirt is cut for comfortable fit, and smartly tailored of military-weight poplin. The 65% Dacron® polyester/35% combed cotton fabric delivers the comfort you want plus the permanent press convenience you demand. Choose khaki, blue or white. Short sleeves $16. Long sleeves $17.

Discovery Tours

EAST AFRICA SAFARI
Feb. 3 to 21, 1982
Feb. 24 to March 14, 1982
Discover the exotic world of East Africa on game drives with the American Museum's Curator of Mammals, Dr. Richard G. Van Gelder. Twenty-five participants will visit the major wildlife reserves of Kenya and Tanzania. Countless zebra and wildebeest, scores of elephants, giraffes and lions will be viewed from custom made Landcruisers. Spend nights under canvas in comfortable tented camps, as well as in luxurious lodges and hotels. Meticulous travel arrangements will be provided to the Museum by Park East Tours. For further information, write to:

Mister, You Got Yourself a Horse
Tales of Old-Time Horse Trading

Edited, with an introduction, by Roger L. Welsch

Plains folklorist Roger Welsch edits a lively collection of stories by a group of master storytellers—those old-time travelling horse traders. He presents these first-hand accounts just as they were told to Federal Writers Project fieldworkers in the 1930s, and he supplies background information on the narrators and their craft.

Whether you read them as folklore, history, or literary narrative, these stories radiate the gusto of a growing country and the humor, personality, and adventures of that legendary American figure—the horse trader. xii, 207 pages.

George D. Lepp

ings of the Boston Society of Natural History, vol. 42, pp. 1–119, July 1941). Palmer's report, based on his fieldwork in Maine, contains little on taxonomy, ranges, and migration, but it does include a compact life history. It also focuses on aspects of the environment that affect the tern's breeding season and the bird's behavior during the breeding cycle. *Life Histories of North American Gulls and Terns*, by A.C. Bent (New York: Dodd, Mead and Co., 1947), includes the habits of each bird, its food, plumage, voice, range, courtship, eggs, young, nest, and migration. Bent includes a section on the least tern, focusing on its habits and distribution (pp. 170–79). I. Nesbit, who studied terns in Cape Cod for four years, observing their nesting behavior and trying to discover the reason for their population decrease, wrote extensive captions for *National Geographic*'s photo essay "Friend of the Wind: The Common Tern," with photographs by H. Alexander (August 1973, pp. 234–47). "Late-Blooming Terns," by P.A. Buckley and F.G. Buckley (*Natural History*, April 1976, pp. 46–55), discusses the mating, nesting, and nurturing behavior of the royal tern, including descriptions of the variety of coloration in the royal tern's eggs and chicks, the phenomenon of crèche-forming, and the extended developmental period of the young. M. Harwood's "Dawn to Dark, Day In and Day Out, Tern Study Is a Labor of Love" (*Smithsonian*, August 1980, pp. 28–37) is an account of life on an island "laboratory" devoted to tern study told in a humorous and informative manner.

Weathering Heights (p. 72)

C. von Fürer-Haimendorf's *The Sherpas of Nepal* (Berkeley: University of California Press, 1964) covers the

social and religious life of these people; his book on life in highland Nepal, *Himalayan Traders* (New York: St. Martin's Press, 1975), is in some sense a sequel in that it describes the transformations in Sherpa life that have occurred since his previous book. *Himalayan Traders* analyzes the trans-Himalayan trade, which once represented an essential element in the Sherpa economy; the economic and political upheavals that have changed the lives of these mountain dwellers; and Sherpa reaction to the decline of trade. *Man in the Andes*, edited by P. T. Baker and M.A. Little (Stroudsburg: Dowden, Hutchinson, and Ross, Inc., 1976), is a multidisciplinary study of the Quechuas, comprising seventeen articles by scientists investigating the biology of human populations at high altitude in the district of Nuñoa and other parts of southern Peru. It includes chapters on "Growth and Morphology at High Altitude," by A.R. Frisancho (pp. 180–207), "Natural Exposure to Cold," by J.M. Hanna (pp. 315–31), and "Physiological Responses to Cold," by M.A. Little (pp. 332–62). See also A.R. Frisancho's text, *Human Adaptation* (Saint Louis: C.V. Mosby Co., 1979). H.C. Buechler and J.-M. Buechler's case study on *The Bolivian Aymara* (New York: Holt, Reinhart and Winston, Inc., 1971) focuses on the inhabitants of Compi, a community on the shores of Lake Titicaca on the Bolivian high plateau. The Buechlers view the community as part of a complex system rather than in isolation; from this standpoint, they report on Compi's economic and social organization, childhood in the community, the family, the fiesta system, and religion. The book also provides references and recommended readings.

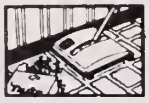
TIRED OF BUYING JUNK?

GET A Dorsay Floor & Carpet Sweeper



The DORSAY Floor and Carpet Sweeper is built with care by people who make nothing else, for people who believe household appliances should last a lifetime. We also think appliances should be noiseless, convenient, pretty, efficient and require no electricity.

If you feel the same way, you're going to love a non-electric DORSAY Floor and Carpet Sweeper. We believe it is the lightest, strongest, most efficient and convenient appliance of its type on earth. In the past 6 years, thousands of commercial users worldwide (airlines, hotels, restaurants, etc.) have confirmed our belief by demanding only our floor sweepers. A DORSAY Floor and Carpet Sweeper weighs under 3 pounds, is only 9 inches wide and works as well on a bare floor as it does on carpet. It picks up sugar, sand, pet hairs, paper clips, ashes and much more. Who really needs a vacuum cleaner?

Yes, it looks like an old-fashioned "carpet sweeper" (except it is far smaller and about ⅓ the weight), but there the similarity ends. The DORSAY Floor and Carpet Sweeper is patented and based on entirely new technology. Its natural hog bristle brush will outlast synthetics by about 3 to 1. It should last a lifetime if properly cared for in ordinary household use. The DORSAY Floor and Carpet Sweeper baked enamel surface wipes clean with a damp cloth. Horse hair corner brushes clean right up to the wall, and the whole sweeper can be hung up in 2 inches of wall space. EVERY PART IS REPLACEABLE AND CARRIED IN STOCK.

If you can find any other sweeper that can make the above claim, BUY IT. We are sure you can't, so we want you to try our DORSAY Floor and Carpet Sweeper.

Pick up unexpected messes in seconds.

Clean stairs quickly & easily.

Reach hard-to-get-at-places.

The Dorsay Floor & Carpet Sweeper

NO NOISE, NO HOSE, NO ELECTRIC CORDS

Only $19.88 plus $3.50 for ship./hand

ARCHEOLOGY TOUR TO MEXICO January 11-29, 1982

ANCIENT MAYA ARCHEOLOGY February 1-18, 1982

Discover the ancient civilizations and archeology of pre-Columbian Mexico and the Maya world with the American Museum's C. Bruce Hunter. Sites on the Mexican tour include Mexico City, Cuicuilco, El Tajin, Jalápa, Cholula, Teotihuacan, Tula, Oaxaca, Mitla, Monte Alban, Cuernavaca, Xochicalco and Taxco. The Maya tour includes visits to Merida, Dzibilchaltun, Chichen Itza, Tulum, La Venta, Palenque, Edzna, Uxmal, Sayil, Xlapak and Labna. Tours include colonial towns, museums and the finest accommodations, and are limited to 18 participants. C. Bruce Hunter is Lecturer in Archeology at the American Museum, and author of A Guide to Ancient Mexican Ruins and a Guide to Ancient Maya Ruins. For further information write to DISCOVERY TOURS, American Museum of Natural History, Central Park West at 79 St., NY NY 10024, or call (212) 873-1440.

THE AMERICAN MUSEUM OF NATURAL HISTORY

Adriatic, Aegean & North Africa Cruise

August 31 to September 1 1982

Discover the ancient and natural wonders of Italy, Greece, Crete, Sicily, Tunis and Malta with seven distinguished lecturers and friends of the American Museum.

Dr. Thomas D. Nicholson, Director of the Museum, invites you to join him on this unique educational vacation retracing the great historical travels of the Greeks, Romans, Phoenicians and Venetians.

Our custom-designed itinerary will be executed by Swan Hellenic whose meticulous arrangements assure you of a relaxed, care-free vacation.

Discuss the fascinating ancient sites with renowned experts in Classical times... see and identify a host of European birds in migration with our staff ornithologist... explore beautiful islands, sea coasts and volcanoes with our Museum geologist... share evenings on deck with Dr. Nicholson learning of the ancient navigators and the stars that guided them.

For further information send us the postage-paid insert card in this issue of Natural History, page 87, or call the Discovery Tours Office, (212) 873-1440. Discovery Tours is the American Museum's travel program whose office is in the Museum complex, Central Park West at 79th Street, New York, NY 10024.

Pin Cherry Perceptions

The language we use in our investigations of nature affects the questions we ask and the answers we get

by Robert E. Cook

In late April and May, when birches turn New England's hillsides pale green and swamps grow pink with red-maple buds, the blossoms of pin cherry burst out in an umbrella of white-petaled flowers surrounded by a haze of honeybees. The rise of sap from the cherry's roots brings a reddish hue to the shiny black bark with its horizontal gray lenticels. The pin cherries are soon lost in the foliage of the summer forest, but they become prominent again in August when the ripening fruits draw late-nesting waxwings and flocks of migrating robins to harvest strings of cherries. Without much delay the birds process the sweet pulp and pass the stony seeds on to the forest floor.

Conspicuous members of the northern hardwood forests of the Northeast, pin cherries (*Prunus pensylvanica*) never grow very old, seldom living beyond thirty years in the forest. The biology of this short-lived species seems designed to rapidly produce a large number of single-seeded drupes, fleshy fruits with an inner stone that holds the seed. A young pin cherry may first show flowers only four years after germination, when it is barely a sapling. Peak yields occur between the ages of fifteen and twenty-five, and over its entire life, a healthy, free-growing female may form more than 32,000 drupes.

The fruiting pin cherries are often found thriving on land that has recently seen disturbance or destruction of the vegetation: about the edges of breaks and trails or scattered among the young oaks, beeches, and sugar maples that revegetate cutover land. The species is sometimes called fire cherry because its seedlings quickly occupy burned-over forests, where they may form a single stand of rapidly growing foliage. It also follows promptly in the wake of loggers, emerging through the piles of slash and raw stumpage within a year or two of the cut. As salvager of ravaged landscapes, the pin cherry has recently captured the attention of ecologists investigating the recovery of damaged ecosystems.

By the middle sixties, the growing alarm among environmentalists concerning the devastating impact of some human activities on wilderness areas had thrown the wisdom of forest clear-cutting into question. Clear-cutting is economically efficient: all the trees in a large tract of forest are cut to the ground, stripped of branches, and carried off to the sawmill. Many years later a new forest has usually replaced the old one through a revegetation process called succession. Ecologists asked whether the economically efficient practice of removing all the trees, rather than selectively cutting choice individuals, might adversely affect the pattern of subsequent forest recovery and permanently damage the land. They were particularly concerned about any decline in soil fertility—the capacity of the deep layers of humus to provide the mineral nutrients needed for the growth and development of later forests. In mature stands, much of the nutrient capital, such as nitrogen, potassium, and calcium, can be tied up in living plant tissue or intimately complexed with the decomposing layers of organic matter on the forest floor. Ecologists wondered whether, in addition to the minerals that depart with the harvested timber, clear-cutting might cause a loss of nutrients through erosion and excessive runoff in stream water.

Herbert Bormann of Yale's School of Forestry and Environmental Studies and Gene Likens of Cornell University decided to test these ideas, and in 1964 they established the Hubbard Brook Experimental Watershed Study on a tract of second-growth hardwood forest in the White Mountains of central New Hampshire. The experimental unit they manipulated is known as a watershed, an area of forest draining into a single stream. Two adjacent watersheds at the headwaters of Hubbard Brook were chosen: one was to be clear-cut for the experiment and the other, the control, was to be left uncut. By constructing a notched dam, or weir, at the head of each stream, they could measure stream flow from both watersheds and periodically sample the water to assess nutrient content and the loss of particulate matter from erosion. All the trees in the experimental watershed were cut, and the effects of devegetation were accentuated by the application of herbicides for three years. After the cut, Bormann and Likens, and their students, monitored the water chemistry and the change in the growth and composition of

DINOSAURS OF NORTH AMERICA

"brings back to life the very different world of the distant past—with its exotic and spectacular creatures."
—John H. Ostrom, Curator of Vertebrate Paleontology, Peabody Museum of Natural History, Yale University

Now, in the most authoritative book of its kind—and the first devoted exclusively to North America—Helen Roney Sattler describes more than 80 kinds of dinosaurs that roamed the continental United States and Canada. For 140 million years, dinosaurs dominated the earth. The fossils they left help us to know what they really looked like, from the gigantic *Brachiosaurus*, 40 feet tall and 80 feet long, to *Nanosaurus*, about the size of a chicken.

Dinosaur history is told against a background of vast geological changes. Included is information about exciting discoveries being made today and the latest theories about what caused dinosaurs to become extinct. For future fossil hunters, this book is a must. For everyone, reading it will be an adventure.

the cut forest and compared this with the control.

Bormann and Likens have recently published the results of this experiment in *Pattern and Process in Forested Ecosystems* (New York: Springer-Verlag, 1979), and it is a brilliant piece of ecological investigation. In an effort to achieve a broad understanding of forest systems, they have constructed an ecosystem model based on the Hubbard Brook data to predict the recovery of a forest following the devastation of its vegetation. In this model, the ecosystem—all of the dead and living organisms as well as the inorganic nutrients—is pictured metaphorically as a highly integrated organic entity that is subjected to a serious wound or disturbance, much like a severe injury suffered by an animal. The entire system undergoes a process of recovery (succession) in which internal homeostatic mechanisms repair the damage and return the system to a normal state. Bormann and Likens divide their model of forest recovery into four phases: an early period of declining biomass through the decomposition of dead slash; a hundred years of succession as biomass accumulates; a transition time when old trees begin to die, creating local gaps of disturbance; and a long-term steady state when the forest is a mosaic patchwork of mixed-age trees in different stages of succession. The goal of this recovery process is the original plant community that covered the landscape prior to the intrusion of humans. This image of a primeval forest has haunted plant ecologists for more than half a century, touching their deepest feelings for unspoiled wilderness. Armed with this conceptual model and its underlying organismic metaphor, Bormann and Likens set about interpreting the remarkable results of their deforestation experiment.

The most fundamental effect of clear-cutting was a dramatic increase in the volume of stream flow, particularly during spring snowmelt and after heavy rainstorms. One midsummer shower in 1969 generated a peak flow that was more than three times higher in the cutover watershed than in the control. Precipitation, which would normally have been absorbed through the roots of living plants and transpired via evaporation into the atmosphere, moved out of the watershed in a massive flush of water accompanied by enhanced concentrations of nutrients. Dissolved nitrogen, for example, which is so critical to the growth of plants, peaked nearly 160

For the eighth year, we invite you to witness North America's greatest wildlife spectacle:

The Seals on the Icepack

MARCH 4 to 9, and MARCH 8 to 13, 1982

Each year, thousands of seals end their migration in Canada's Gulf of St. Lawrence and congregate on the icepack, turning it into a huge natural nursery as the females give birth to their babies.

We are the only company in the world with the experience, knowledge and audacity to offer these unique, thrilling and exhilarating tours.

Detailed brochures of the tours and a copy of our newsletter which lists all our fascinating travel programs, available from:

times higher in the stream flow of the devegetated watershed than in the forested area. The authors concluded that "the ecosystem responds to enforced devegetation by dumping substantial quantities of nutrients into drainage water." Much of this loss of minerals derives from the decomposition of dead and dying vegetation on the forest floor. Equally important, however, is an increase in the erosion of soils throughout the watershed. Particulate matter in streams is proportional to the flow of water, and in the first three years after the forest was cut, the forest floor actually sank three centimeters in depth.

This stark picture of system degradation changed dramatically as soon as the herbicide treatments ceased and the vegetation was permitted to grow. Within four or five years the concentration of dissolved nutrients in the drainage water was close to that of the uncut watershed, particulate matter was significantly reduced, and in general, stream flow during the summer months began to approach the small volumes normally trickling out as forest ground water in midsummer. When vegetation returns after clear-cutting, foliage quickly overgrows the cut stumps and decaying piles of litter and fresh roots proliferate in the soil, consolidating the crumbling humus against erosion and absorbing ground water rich in nutrients. Precipitation percolates out of the watershed through the plants, moving upward in conducting vessels to the surface of the leaf and leaving through stomatal evaporation. During this passage, the plant extracts minerals critical for growth. This solid stream of water within the mass of the shoot provides the force for plant growth by increasing the turgor in new cells at the growing tips, expanding cell walls and slowly unfolding new leaves. Vigorously developing plants live much like fish in a stream, depending on the flow of water to provide continual support and sustenance.

Herein lies the short-lived but exalted glory of pin cherry, for in many New England forests, it is the primary species responsible for this dramatic turn of events. Its influence is felt so quickly because it really begins living in the forest—in the form of dormant seeds in the soil—long before a cut. There may be as many as fifty pin cherry seeds in each square meter of forest loams. In the Northeast, many of these individuals have probably been leading quiet lives since the last flush of cherries followed the lumbering of the forests soon

FROZEN STIFF?

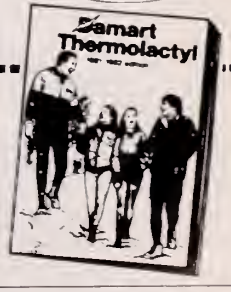
It's 10° outside . . . Even getting colder. So you bundle up in layers and layers of heavy clothes. First with long underwear . . . then bulky, restrictive thermalwear on top.

Oh, you were warm all right. Like in a Turkish bath. Because you began to perspire from all your activity. And perspiring in that mountain of clothes is like perspiring in a plastic bag! The perspiration is locked in. So there you are. Wet and miserable.

But now, at last, Damart has solved the problem. Because Damart invented underwear that keeps you *warm, dry and comfortable* no matter how cold it is or how long you stay out. Underwear that's soft and light so you can move easily. Underwear knitted to let the *perspiration evaporate through* so you always stay warm and dry next to your skin. Nothing else does this like Damart!

Damart does this with a new miracle fabric—Thermolactyl. You can wear Damart indoors too, and turn your thermostat down into the 60's. You'll feel perfectly comfortable and enjoy dramatic savings in home heating costs.

Damart is so comfortable that the Mt. Everest climbing expedition wears it. So does the Chicago Bears Football Club, New England Patriots and Philadelphia Eagles.



Our free color catalog tells the full Damart Thermolactyl story and displays the whole Damart line for men and women, *including tall sizes.* Send for your FREE copy now!

after the turn of the century. Others have arrived more recently with the passage of birds. The cutting of the trees leads to the massive germination of these seeds and the rapid transformation of the decomposing litter into a garden of seedlings. Pin cherries display one of the highest growth rates of the prominent forest species, forming a closed canopy of knee-high saplings within a year or two of release from life as a seed. Fruit production soon begins, and the high fragrance and spring blossoms of *Prunus pensylvanica* will command the canopy for the next twenty years.

Pin cherry eventually relinquishes the stage to other hardwood species, such as beech, yellow birch, and sugar maple, that dominate the uncut forest. Bormann and Likens drew their account of pin cherry biology from the work of Peter Marks, a plant ecologist at Cornell who studied extensively in the Hubbard Brook forest. Marks found small saplings of the future hardwoods, which had apparently survived the lumbering, growing in the midst of a thicket of pin cherry seedlings within a couple of years after the start of revegetation. Thus all the individuals in the succession are present at the beginning. Mortality among the dense cherry seedlings is extremely high, with only one out of twenty-five reaching the age of peak reproduction. Individuals of beech and maple fare much better than the smaller cherry plants because they can tolerate the deep shade cast by the overstory. These small hardwoods achieve some marginal growth each year, and by the time they penetrate the canopy, the oldest pin cherries have begun to senesce, freeing space for the emerging hardwoods. With time the forest's original composition is restored.

The coincidence of the cutting of the forest and the massive germination of pin cherry seeds is striking. Equally remarkable is the relationship between the high growth rate of these seedlings and the recovery of control over the export of nutrients through ground water. Finally the deposition of a new population of seeds through abundant fruit production appears to renew the potential for a similar response in the future. Bormann and Likens find this biology so persuasive that they call it the buried seed strategy and assign it a critical function in their forest model. The adaptations of pin cherry—its dormant seed populations, simultaneous and rapid germination, high rate of growth, abundant fruiting, and early senescence—are interpreted in their model as part of a plan

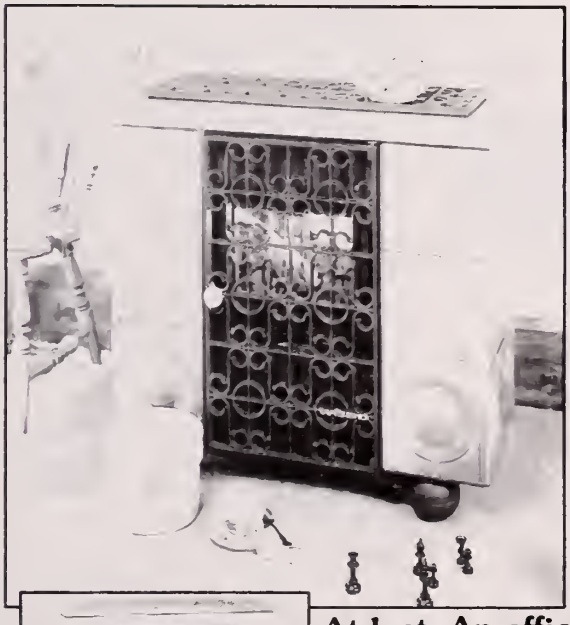
for recovery of the ecosystem following catastrophic destruction. The "behavioral patterns of species using this strategy," they write,

> suggest that it may have evolved specifically in response to the highly specialized conditions that follow serious disturbance of a previously intact ecosystem. In terms of system dynamics, the strategy is not simply exploitation of an injured ecosystem but is also part of an elaborate feedback mechanism that acts rapidly to limit temporarily accelerated nutrient export and return the system to a condition of greater stability.

At the risk of being picky, we can ask whether an ecosystem, the ensemble of living organisms and associated mineral constituents, can become "injured." Has pin cherry evolved dormant seeds to "limit . . . nutrient export . . . and return the system to . . . greater stability," as implied in the quote above? Ah, you say, this is but a figure of speech, not to be taken literally. At this point readers may accuse me of getting stuffy about language and metaphor in science. I plead guilty to the charge of extracting a single quote, out of an exceptional work of scholarship, upon which to hang a fine distinction, and I ask the reader's indulgence while I try to delineate an important matter of interpretation.

What's wrong with an organismic metaphor lying within the model of forest recovery? After all, an ecosystem behaves *as if* it were a living organism. And, by analogy with an organism, it appears to have a mechanism of self-repair, a healing process that leads to the return of normal function. Why couldn't a process much like the capacity for tissue reconstruction in the individual have evolved in the ecosystem? Does the choice of the language with which an abstract model is constructed have any effect on the quality of the science?

I am as susceptible as anyone to the intuitive beauty of a finely chosen metaphor in any medium. The problem arises when our metaphors take on a life of their own and become so deeply rooted in our minds that they generate fundamental misconceptions about nature. Metaphors do more than affect how we understand our perceptions; they actively shape the kinds of questions with which we approach our ignorance. Once passed on to our students, metaphors truly acquire independent flight, free from the contextual qualifications that accompanied their birth.



Perhaps the question of ecosystem evolution can be clarified through appli-

cation of a simple Darwinian test to the biology of pin cherries. Most evolution occurs through natural selection, which causes an increase in the frequency of those inherited traits that allow individuals to leave relatively more offspring in future generations. In many instances these traits of individual organisms will also promote some ecosystem process, such as the recovery of nutrients from ground water. But suppose, for a moment, that a mutation occurred in a pin cherry seedling that decreased the efficiency or rate of recovery of an injured ecosystem but had the effect of increasing the number of future grandchildren descended from this individual. For instance, I can imagine a gene that channels energy into greater fruit production at the expense of an expanding canopy. Would such a gene spread through the population, decreasing the rate of transpiration and ecosystem recovery? If it increased the fitness of the individual cherry tree, we can say that it would, with high probability, soon characterize all the pin cherries in the population. Similarly, a gene that caused individual trees to leave relatively fewer descendants than neighbors would never increase in frequency, independent of its effects on ecosystem recovery. The appearance of adaptive order in the properties of the whole ecosystem—homeostasis, feedback recovery, stability—is just that, an appearance of design.

I suspect my colleagues who study ecosystems may still prefer a holistic vision of system stability. The quality of the science in the Hubbard Brook study is not in question here. Bormann and Likens have constructed a piece of research that is brilliant, synthetic, and rigorous, and it will surely prove immensely important for predicting the long-term effects of disturbance on natural habitats. At issue is the way we choose our conceptual language while creating our interpretations of nature. As the great geneticist Theodosius Dobzhansky said, nothing in biology makes sense except in the light of evolution. Should not the figurative language with which we dress our perceptions at least harmonize with the principle of natural selection? To do so, the words we choose must reflect the perspective of the individual, whose growth and reproduction are the gist of fitness. Ecosystems evolve only as their constituent organisms live and die, and our sense of adaptive design is only a mirage.

Robert E. Cook is associate professor of biology at Harvard University.

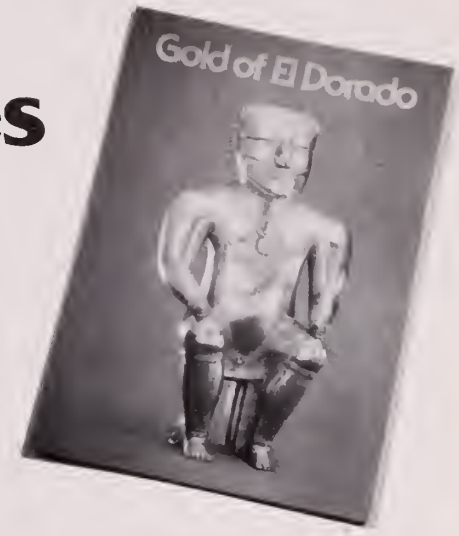
UNION CITY, NEW JERSEY 07087

For the fifth year, we invite adventurous travelers to join us on a unique travel experience:

The Snows of Kilimanjaro

FEBRUARY 5 TO 22, 1982



Our expedition begins with a wildlife safari to Ngorongoro Crater, the Serengeti Plains and Lake Manyara, where we also undertake hikes to prepare us for the ascent of Africa's highest mountain, crowned with its permanent icecap.

In order to make the climb not only memorable but enjoyable, we allow plenty of time for resting at huts and camps to become used to the high altitude.

Detailed brochure of the expedition and a copy of our newsletter which lists all our fascinating travel programs, available from:

An Art Book That Took Centuries To Create

It took the American Museum of Natural History four years to arrange its exceptional exhibition of more than 500 pieces of ancient gold from Colombia. But those few years are a brief time when compared with the decades archeologists have spent digging (literally!) and studying the gold artifacts from tombs, caves, and buried sites. And all that time is short when compared with the many centuries prehistoric Indians practiced their craftsmanship and artistry to create these treasures.

So when it became the United States sponsor for this outstanding collection, the American Museum faced a dilemma. Could we do justice to all this effort and scholarship and beauty? We think we have. First, by dramatically displaying *Gold of El Dorado: The Heritage of Colombia* in one of our largest halls. The glowing reports from visitors tell us our efforts have been worthwhile. If you don't have a chance to see the show for yourself in New York, we hope you will see it in Chicago, San Francisco, or New Orleans on its year and a half tour.

The second challenge for the American Museum was the creation of an appropriate book to accompany the exhibition. We decided against a traditional catalog; against a small, boring volume with tiny black-and-white pictures that could never do justice to these fine objects. Instead, we decided to present a select number of the finest pieces of pre-Columbian gold in a large, stunning format. And to represent the three important elements that make a great art book we chose outstanding professionals.

First, photographer Lee Boltin. One of the greatest photographers of art objects, he also took the famous pictures of the Tutankhamun show. We sent him abroad to find and record great pieces of pre-Columbian art.

Second, archeologist Warwick Bray, from the University of London. One of the world's foremost authorities on pre-Columbian art, Bray is also a skilled writer, able to present fascinating background in a succinct, readable essay in the book. Dr. Bray organized the Colombian gold exhibition in London.

Third, Harry N. Abrams, Inc., America's leading publisher of fine art books. In a co-publishing venture with the American Museum, Abrams designed the book, supervised the preparation of 30 large color plates, and monitored the fine-quality printing.

The result is an unprecedented exhibition book. It is bold and big—each plate is 16 by 11½ inches—bigger than this magazine opened up. The paper is heavier than most posters. In fact, many persons have purchased two copies of the book in order to have one set of these fine art prints for framing.

And now for the happy ending. Because the Museum is a co-publisher, we are able to offer this soft-bound art book at a major savings from its normal retail price of $12.50. We are pleased to offer *Gold of El Dorado* to subscribers for only $6.25—a 50% savings off its regular price. This special offer is valid only during the exhibition and only while our limited supply lasts. We suggest that you order one or more copies immediately. Of course, if you are not satisfied after you have had an opportunity to examine it in your home, simply return the book and the Museum will refund the purchase price.

Patterns of Paradise

" I [s]hall now describe their method of makeing cloth, which in my opinion is the only curious manufacture they have, all their cloth is I beleive made from the bark of trees, the finest is made from a plan[t] which they cul[t]ivate for no other purpose.... They let this plant grow till it is about six or eight feet high the stem is than about as thick as ones thum or thicker, after this they cut it down and lay it a certain time in water, this makes the bark strip easy off the out side of which is than scraped off with a rough shell, after this is done it looks like long strips of raged linnen. These they lay together, by means of a fine paste made of some sort of a root, to the breadth of a yard more or less and in length Six, Eight or ten yards or more according to the use it is for, after it is thus put together it is beat out to its proper breadth and fineness upon a long square piece of wood with wooden beaters the cloth being kept wet all the time; the beaters are made of hard wood with four square sides and about a foot long including the handle which is round, each of the square sides are about 3 or 4 inches broad and cut into grooves of different fineness this make the Cloth look at first sight as if it was wove with threed.... The finest sort when bleached is very white and coms nearest to fine Cotton. Thick cloth especialy fine is made by pasting two or more thickness's of thin cloth made for that purpose together."

The Journals of Capt. James Cook: The Voyage of the Endeavour *1768–1771*

Wherever James Cook met indigenous tribes on his voyages in the South Seas, he found the "curious manufacture" of bark cloth in use—for clothing, bedding, swaddling, bandaging, burials, and for buying and selling. He collected all kinds of bark cloth products, including magnificent cloaks from Hawaii, rolls of fine white linenlike cloth, effigies and masks, and thick mats decorated with colorful geometric patterns. To the British of Cook's day, the South Pacific was an exotic paradise, inhabited by natives "wearing nothing but the bark of trees." Interest in bark cloth was great enough that some of Cook's specimens were cut up for a catalog—a bark sampler if you will—with the somewhat extended title: "A Catalogue of the Different Specimens of Cloth Collected in the Three Voyages of Captain Cook to the Southern Hemisphere, with a Particular Account of the Manner of the Manufacturing the Same in the Various Islands of the South Seas, Partly Extracted From Mr. Anderson's and Reinhold Forster's Observations, and the Verbal Account of some of the most knowing of the Navigators with Some Anecdotes that Happended to them Among the Natives."

Cook's catalog and 125 other fine specimens of bark cloth (properly called tapa) will be on display in "Patterns of

Painted bark cloth is stretched over a rattan frame in this night-dance mask from Papua New Guinea.

Ron Testa/Field Museum of Natural History

Paradise," a new exhibition opening at the American Museum of Natural History on Wednesday, November 18. The exhibition comes from the Field Museum of Natural History in Chicago, which has one of the best collections of Oceanian art in the United States.

The making of tapa is an ancient craft, and anthropologists think it may date back to 2,000 B.C. or earlier. By 1,000 B.C. tapa making was widespread in Asia and Indonesia, where the material was used for much the same purposes as woven cloth elsewhere. In the eighteenth century, Pacific islanders wearing "nothing but bark" were actually handsomely attired in dresses, robes, blouses, and skirts with intricately painted patterns, often embellished, among the ruling classes, with feathers and other decorations. In Hawaii, skirts, called *pa'u*, were made of as many as ten layers of tapa, each up to six or seven feet long. Kamamalu, the wife of King Kamehameha II, who ruled Hawaii in the first part of the nineteenth century, was said to have worn a ten-layered *pa'u* that was so long and unwieldy that she had to lie down to have it put on. When Cook was killed in the Hawaiian Islands in 1779, his body was buried in the traditional tapa shroud.

There are a number of tropical plants with a pliable inner bark suitable for making cloth, and in most places where these plants grow—Africa, South America, Asia, the Pacific—bark cloth is made. The paper mulberry is the favored plant in the Pacific; the islanders still make tapa in much the same way that Cook described—by stripping off the bark and then removing its outer layer to expose the soft inner skin. Often the bark is soaked before it is beaten. Most tapa beaters have a ribbed or textured surface; beating is done with increasingly finer textured beaters, until finally either a beater with a smooth face or one with a carved pattern to be imprinted on the finished cloth is used. The beating of tapa—women's work—is traditionally a very public and social

Broad bands with sawtooth edges were probably painted freehand on this tapa cloth from the Samoa Islands.

activity, often performed like a symphony with each beater producing a different tone and rhythm. On islands where tapa making is a thing of the past, older women remember the tapa beating of their childhood with nostalgia.

The finished cloth is often dyed, painted, or printed. Each group of Pacific peoples has its characteristic colors and patterns, which range from somewhat realistic renditions of plants and leaves to geometric, repeating designs.

"Patterns of Paradise" was organized by two members of the Field Museum staff—John Terrell, associate curator of Oceanic archeology and ethnology, and Anne Leonard, anthropology researcher. Splendid examples of tapa—among them specimens collected by Cook—are included, as well as stonework, pottery, woodcarvings, tapa tools, and other artifacts from the Pacific islands. The traveling exhibition will remain in Gallery 77 of the American Museum until February 14, 1982.

Patterns of Paradise

An exhibition containing more than 150 examples of tapa from the Pacific and Caribbean islands, Southeast Asia, Africa, and South America will open in Gallery 77 of the American Museum on Wednesday, November 18. See article on page 104.

Patterns of Paradise will be free to all Museum visitors.

Dance Première

Hurakan (*Heart of Heaven*), a full-length modern dance piece by the Sundance Company, will have its New York première in the Museum's Auditorium on Sunday, November 1, at 2:00 P.M. The Sundance Company spent two years conducting research on the ancient Maya before the piece began to take its final form. Based on Maya myths and symbolism, *Hurakan* is not a re-creation of ancient dances but an impressionistic dance, created to give the viewer a sense of the Maya culture.

The program is free to all Museum visitors.

Glories from the Sea

On the weekend of November 21 and 22, Education Hall will turn into a veritable paradise for people intrigued and awed by the beauty of shells. For this *Member's Shell Weekend*, samples from the Museum's collection of more than two million specimens, and from the collections of the New York Shell Club, will be on display; scientists from the Museum's Department of Invertebrates will be on hand to discuss mollusks and their life styles; and a Mollusk Film Festival will be screened in the Auditorium. Many more activities are planned for this two-day look at some of the world's most beautiful creatures. The program is free for members, $2.00 for nonmembers. No reservations are necessary.

John Burroughs: Poet-Naturalist

How Far Are We from Home: John Burroughs, a film portrait of the American poet-naturalist, will be shown in the Auditorium on Wednesday, November 18, at 7:00 P.M.

Through his books and articles, Burroughs (1837–1921) probably did more than any other writer to create an interest in the natural sciences and outdoor life. His essays were used as the basis for the first nature studies in American schools.

The program will be free to all Museum visitors.

Ghost Stories

All manner of spooks and spirits will haunt the Museum on Sunday, November 1. Still reveling from Halloween the night before, they will join Laura Simms and other storytellers for sessions of *Ghost Stories from Around the World*. There will be three sessions: at 11:00 A.M. and at 1:30 and 3:30 P.M. The morning session, with slightly friendlier ghosts, is especially geared for children up to age seven. The two afternoon sessions are for all ages. Tickets are $1.00 for members,

Tapa headbands (deep orange) and loincloths from the Solomon Islands derive their color from turmeric.

$2.50 for nonmembers. Reservations are required. For information call (212) 873-1327.

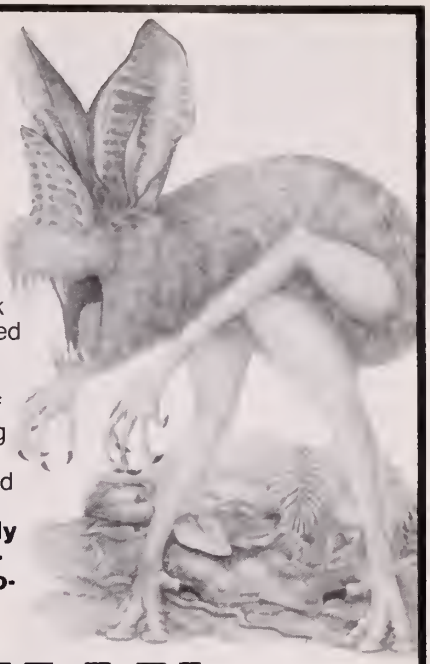
Classical Dances from Cambodia

Only a year ago it was feared that the classical dances of Cambodia had vanished under the Khmer Rouge regime. Nevertheless, for five years, a troupe of artists, musicians, and dancers managed to disguise themselves as farmers before working their way through the Thai refugee camps to get to the United States. This troupe will perform in the Museum Auditorium on Sunday, November 15, at 2:00 P.M. in a program presented in cooperation with the Society for Asian Music.

Training for Khmer dance begins in early childhood when the limbs are supple enough to bend in the characteristic curves of the classical dances. Many of the dancers in this group trained in the Royal Palace Dance School in Phnom Penh and once danced with the Palace troupe.

The program is free to all Museum visitors. For information call (212) 873-1300, ext. 559.

Sky Show



Beginning November 25, the Sky Show at the Hayden Planetarium will be *Star of Wonder*. This show has been delighting New York holiday audiences for more than forty years. It journeys back 2,000 years for a look at the sky of Bethlehem at the time of Jesus' birth. What was the "star of wonder" that led the wise men on their journey? Was it a comet? A bright meteor? Some have suggested that it was a nova or even a rare grouping of the planets. The show will run through January 5, 1982, and is a celebration of the holiday season for one and all. For more information call (212) 873-8828.

To Dance One's Dreams

Myths and stereotypes concerning Native Americans have acted as barriers to cultural communication between Indians and non-Indians. On Sunday, November 8, at 2:00 P.M. in the Auditorium, a new bridge will be explored: communication through movement and dance. Solaris, a modern dance company, will perform in conjunction with dancers from the Lakota Sioux nation. *Ihanbla Waktoglag Wacipi* (*To Dance One's Dreams, Visions, or Exploits*) combines traditional dances performed by the Lakota Sioux with Solaris's interpretations of some of the modern-dance legends and myths.

This free performance will be the New York première of the work. For information call (212) 873-1300, ext. 559.

Following the Caribou

by John P. Kelsall

CARIBOU AND THE BARREN-LANDS, by George Calef. *Canadian Arctic Resources Committee*, 46 Elgin Street, Ottawa, Ontario K1P 5K6, *$34.95; 176 pages, illus.*

An old Chipewyan Indian proverb says that "no one knows the ways of the wind and the caribou." While this is still partly true, George Calef in his beautiful new book *Caribou and the Barren-lands* shows how far knowledge of this once mysterious animal has advanced.

The caribou of northern North America have interested succeeding generations of explorers, traders, missionaries, settlers, and scientists since the sixteenth century. It is fair to say that a good deal of human endeavor, and simple subsistence, could not have been maintained had it not been for the ubiquitous caribou and for the meat and hides that they provided. Settlements and seasonal camps were strategically placed so that once or twice a year an abundance of caribou would migrate by and provide the hunters with the necessities of life. When the caribou did not come, and that sometimes occurred, hardship or starvation resulted.

The migration and numbers of the caribou were a mystery to man until the twentieth century. The realization that the same caribou that were hunted on the arctic coast in summer by Inuit (Eskimos) were also hunted in the forest in winter by Indians was slow to become generally accepted. Despite great reductions in the numbers of the animals on the peripheries of their ranges, some instances being recorded near the turn of the eighteenth century by Samuel Hearne and Sir John Franklin, most people believed that there were vast untapped herds in the uninhabited centers of their ranges. As late as 1930, George Critchell-Bullock wrote that the caribou as a whole were safe because "all but the flankers of the annual movements [are] immune from systematic slaughter." In the early twentieth century Ernest Thompson Seton estimated that the Canadian Barren Lands held 30 million caribou "with the wind blowing through their whiskers." That figure haunted successive generations of caribou biologists who knew that the ranges involved were unlikely to have held one-tenth that many animals.

Much of the mystery of caribou movement and numbers began to disappear when biologists were able to survey and census from the air. Development and use of bush aircraft, on skiis in winter and floats in summer, made all the caribou ranges safely and quickly accessible by the 1930s. *Caribou and the Barren-lands* draws primarily on knowledge gained during the past thirty years by scientists using air transport.

Profusely illustrated with the author's own superb photographs, the book must not be relegated to the "coffee table" category. Sponsored by the Canadian Arctic Resources Committee, Calef's book makes a strong plea for the conservation of the caribou while providing exhaustive information about the life cycle, ecology, and management of this remarkable animal.

Part I is devoted to a year in the life of the caribou, and describes in great detail

the cycle of migration and all associated phenomena: the spring migration; the attainment of the far northern calving grounds and the birth of a new generation; the formation of great aggregations of insect-tormented animals in summer; the rutting period and a traditional annual hunt by Indians; and finally, the vicissitudes of the often harsh and hazardous northern winter.

Caribou and the Barren-lands deals with North American caribou, and particularly with three herds that traditionally make great annual migrations from winter ranges in the northern coniferous forests to calving grounds and summer ranges far north on the tundra. For his descriptive narrative of spring migration and calving, the author chose the Bathurst herd of the central Canadian mainland as a subject. For his study of caribou in winter, Calef uses the Beverly herd, the next great herd to the east. While they are neighbors, sometimes even exchanging animals, those two herds are considered discrete because they consistently use separate and distant calving grounds—Bathurst Inlet on the arctic coast and Beverly Lake in the central tundra, respectively.

Having spent much of my time from 1949 to 1959 following one or the other of those herds by foot, dog team, canoe, and aircraft, I can honestly say that reading Calef's narrative was rather like going home after a long trip. Beautifully done! Where I disagreed with the text, it was usually on interpretation rather than observation. It would, after all, be a strange pair of field biologists who saw everything in the same light.

Detail from Age of Reptiles

Dinosaurs and Mammals from Yale

The original 110-foot "Age of Reptiles" mural in the Great Hall of the Peabody Museum took four and a half years to complete and won the artist, Rudolph F. Zallinger, a Pulitzer Prize. The mural depicts thirty dinosaurs in six successive eras of earth history. The 60-foot "Age of Mammals" mural presents the fauna and flora of the Paleocene to the Pleistocene era. Beautiful full-color reproductions of these unique masterpieces are available in two sizes. The larger, deluxe format—over 9 feet long—is a lithographic print on a heavy, durable paper. The smaller version (6 feet long) is printed on glossy paper. Illustrated guidebooks are available for each mural.

To order your copies of these beautiful reproductions, fill in the coupon below and send with your payment to:

Yale Peabody Museum Associates
Department NH81, 170 Whitney Ave.,

If you'd like a wall poster of our distillery's founder, drop us a line

MR. CLAYTON TOSH has more good tales about Jack Daniel than most folks can ever believe.

He'll tell you that Mr. Jack promised marriage to two girls at once in 1875; that nobody ever saw him without a coat and tie; and that he perfected a way of manufacturing his whiskey (called charcoal mellowing) that made it uncommonly smooth. Of course, there's no one living who can vouch for the first two tales. But after a sip of Jack Daniel's, most everyone goes along with the third.

CHARCOAL MELLOWED DROP BY DROP

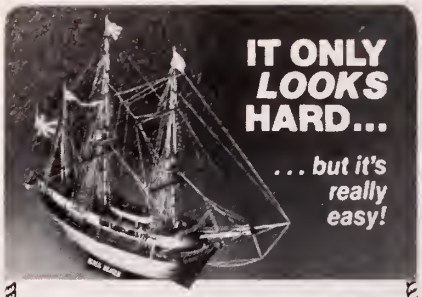
Tennessee Whiskey • 90 Proof • Distilled and Bottled by Jack Daniel Distillery
Lem Motlow, Prop., Inc., Route 1, Lynchburg (Pop. 361), Tennessee 37352

Placed in the National Register of Historic Places by the United States Government.

For the narrative of summer and autumn activities, the author turns westward to the Porcupine herd (named for the Porcupine River). That herd, still numbering about 100,000 animals, ranges impartially back and forth across the international boundary between Alaska and the Yukon Territory. The herd tends to calve in the United States and winter in Canada, crossing the border several times each year. When the caribou cross the Porcupine River in autumn and spring, they are subject to a traditional Indian hunt, which Calef describes graphically.

For the sake of continuity, it might have been easier for the author, as well as the reader, if a single caribou herd had been chosen and followed throughout the year. Perhaps the author wished to show, through contrast between the herds and their habitat, how caribou have adapted to diverse biological and geographical conditions.

An innovative technique is used to present each chapter in part I of the book. First, an accurate and entertaining narrative, designed perhaps for the lay reader, follows the caribou through a particular part of their annual cycle. Each narrative is followed by a more scientific account of the events of the same period. Additional details are given of the seasonal biology and ecology, as well as current thought in the dynamic and argumentative field of caribou—and predator—management. This dual approach comes off well in my view, despite some lingering doubts as to why it was done. Redundancy, which could become a great problem in using such a technique, has been avoided by the author.



Part II, the shorter part of the book, describes the dependence of man on the caribou as a source of meat, hides, bone, antler, and perhaps spiritual well-being, from prehistoric times to the present. The thorny problems of management are described. While the author makes his feelings on some aspects of management clear in earlier text, it is here that he puts them all together.

George Calef has studied caribou for a decade and, in that time, he has observed at all seasons the herds that he has described. Beyond his personal experience with caribou, he is an expert synthesizer of information taken from many sources. He is also an accomplished photographer. His 118 pictures, in color, depict not only the caribou but also a wide array of the fauna, flora, and the biogeography of the country. Adequate maps have been provided so that

IT ONLY *LOOKS* HARD...

... but it's really easy!

The secret's in our kits—imported from Europe—where these historic ship models are hand-crafted in walnut and rich woods by some of the finest model makers in the world. Solid brass, cast bronze and detailed wood fittings are used throughout. The hard work is done for you—most parts are *pre-cut*. Assembly is simple as you follow step-by-step instructions and large scale plans. Everything you need to complete is included, and we guarantee satisfaction.

Even if you have never built a ship before send for our full-color catalog. See how easy it can be to build a museum quality model you will display with pride in home or office. Only $2.00

the reader can follow the text and the caribou.

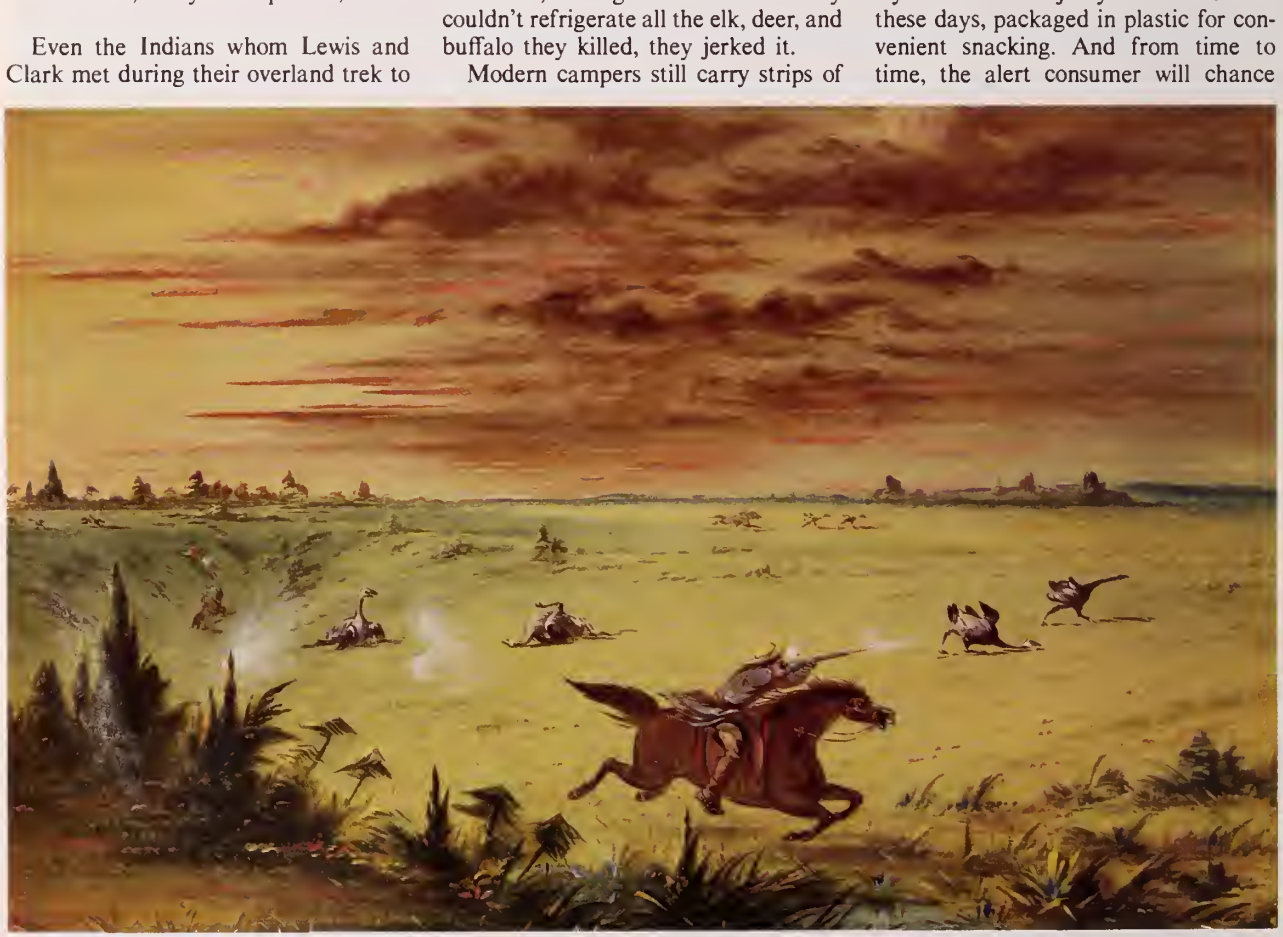
Sponsored by the Canadian Arctic Resources Committee, *Caribou and the Barren-lands* is a credit to both author and publisher. For those interested primarily in fine photography of arctic wildlife, this book provides a feast. While biologists may pick a few nits here and there over minor discrepancies, the narrative is a pleasure to read. The committee's purpose, to contribute to public understanding of a major renewable resource, has been well served.

The real debate over *Caribou and the Barren-lands* will be between people who have been following recent technical arguments over the place of the wolf in the world of the caribou. Calef supports those who say that wolves, and men equipped with the most modern hunting technology, provide simply too much predation for caribou herds to stand. In fact, some argue that wolves alone can cause a caribou herd to decline. Others take the view that since wolves and caribou have evolved and lived together for countless millenniums, wolf control is only necessary in particular places and cases. There has been much spirited debate on this at technical conferences in recent years. George Calef's view is a legitimate one to put forward for consideration, and it deserves a hearing. For my money, however, the jury is still out.

John Kelsall was until recently a senior research scientist with the Canadian Wildlife Service. He is the author of numerous technical and popular articles, including an award-winning book on Canadian caribou.

Cut and Dried

Preserving meat by drying it is a simple, prehistoric process



by Raymond Sokolov

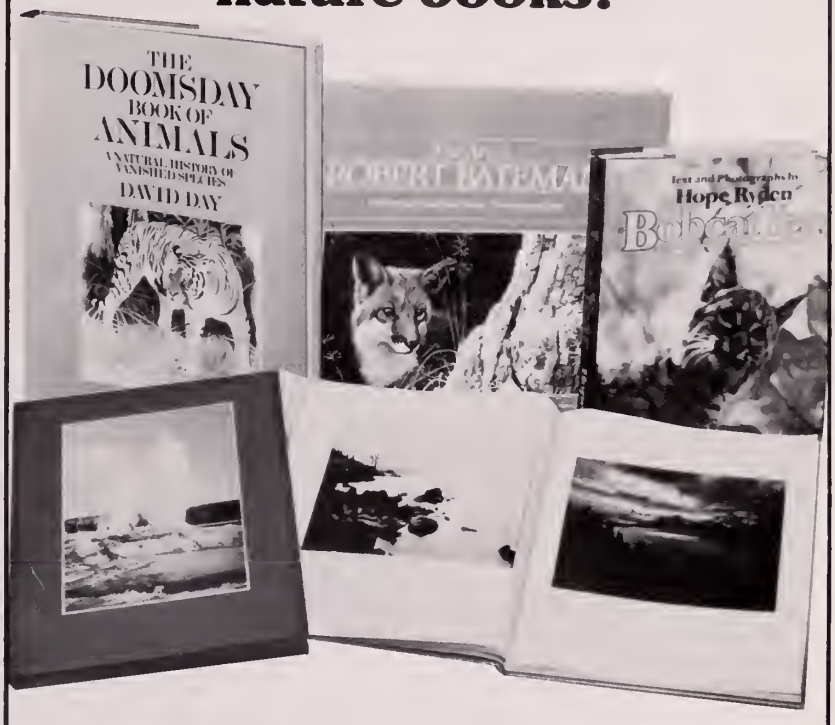
After going 12 miles we were fortunate enough to find a few willows, which enabled us to cook a dinner of jerked elk and the remainder of the dogs purchased yesterday.

The History of the Lewis and Clark Expedition,
by Meriwether Lewis and William Clark, entry for April 26, 1806.

Even the Indians whom Lewis and Clark met during their overland trek to the Pacific Northwest thought it disgusting that white explorers would eat dog meat. But fresh meat was sometimes desperately scarce, especially to the west of the Continental Divide, and the Indian taboo against eating dog left many a cur for less fastidious visitors. Lewis and Clark's other mainstay was, of course, shot game. But since they couldn't refrigerate all the elk, deer, and buffalo they killed, they jerked it.

Modern campers still carry strips of beef jerky with them on the trail. It is a light, compact source of protein with a long "shelf life," and it is tasty. I had some in my pack this summer and enjoyed chewing it on the way up Tuckerman's Ravine, the sheer glacial gouge that runs up to the summit cone of Mount Washington. Almost any country store sells beef jerky over the counter these days, packaged in plastic for convenient snacking. And from time to time, the alert consumer will chance

Painting of rhea hunt by George Catlin. From the Mellon Collection, National Gallery of Art, Washington, D.C.



upon roadside jerky producers who sell this vestige of frontier days in larger quantities. A couple in eastern Maine, who were principally engaged in commercial smoking in their backyard, had a sideline in jerky when I stopped in a year ago. So did a butcher shop in Bay City, Oregon, on the Pacific Coast.

Despite these widely scattered signs of persisting interest in jerky, it is safe to say that this prehistoric method of meat preservation has virtually dropped from view in the United States and that no serious jerky revival is about to engulf us as the next chic food fad following upon the heels of the quiche.

Indeed, I will wager that few Americans can explain what jerky is. The answer is as simple as the process. Jerky is any meat that has been preserved by drying. Most jerked meat is cured in salt, first of all, and then set out to dry, but salting is not strictly necessary. The important thing is to cut the meat in thin strips and then expose them to the air. Some people pin the strips to a clothes line. Others set them outside on racks and protect them from insects with screens. Thick pieces of meat dry more slowly and run a greater risk of spoiling.

The resultant meat not only keeps well, but has a mild flavor and an appealingly chewy texture. The Swiss have perfected jerking to its highest level, using the cool, dry air of the Alps to create that sublime form of beef called Bündnerfleisch and a jerked ham named Bündnerschinken. "Bündner" comes from the Swiss-German name for the mountainous canton of Graubünden. Because the thin air thereabouts is dependably low in temperature, whole pieces of meat can be dried without fear of spoilage and without heavy salting.

The season's most beautiful nature books!

And when Bündnerfleisch and schinken are sliced paper thin, they resemble a fine prosciutto of extreme mildness. Northern Italians serve the same delicacy under the name bresaola.

In the Americas, where the jerking of meat antedates Columbus, Indians cut the flesh of various game animals very thin so that they could dry it in the heat of the sun. Hopis still jerk mutton, beef, venison, and rabbit. In our day, some cooks in Hopiland practice oven jerking. They marinate meat that has been cut across the grain in ⅛-inch slices, then put it on a rack set in a pan and bake it in a 150-degree oven for six hours with the door ajar. The meat has to be turned every two hours. It turns leathery dry and can be eaten as is. Hopis also cook jerky in some fairly elaborate recipes—roasted and served with chili and tortillas, in tamales, in hash or stews, boiled in bite-sized pieces and mixed into drop dumplings, or boiled until tender and then pounded to shreds, or chopped in a blender and combined with cornmeal gravy.

Plains Indians jerked buffalo before the great herds were destroyed forever by white hunters. Lewis and Clark also jerked buffalo meat when they could get it, and reported that it kept much longer than jerked elk. By the late nineteenth century, when the buffalo were gone, the federal government supplied Indians with beef as a substitute, and they dried it in the ancestral manner of their cultures.

Sometimes Indians used jerky as the main ingredient of pemmican (from a Cree word whose root means fat), an almost imperishable concoction consisting essentially of chipped jerky mixed with melted fat, usually stored in a hide sack. Arctic explorers packed pemmican on their expeditions. They would order it by the ton from north country outfitters, who dressed the stuff up with fruit or raisins and sugar. Even so, pemmican seems to have nauseated explorers and possibly contributed to the deaths of some of those who ate a steady diet of it for months on end and, according to one survivor, succumbed to protein poisoning.

In early America, especially in the isolated homesteads of the plains and prairies, slightly more settled folk dried meat in large batches. Louise K. Nickey, in *Cookery of the Prairie Homesteader*, recalls that when she was growing up on a farm in northeastern Montana before World War I, her mother would dice a cup of dried beef, simmer it in two cups of water for nearly an hour and then serve it in a skilletful of milk gravy, along with buttermilk biscuits.

When I was growing up, one occasionally encountered a survival of this dish, made from a commercial dried beef called chipped beef. Old-fashioned cookbooks often feature recipes for such things as creamed chipped beef on toast. And modern supermarkets still sell chipped beef, which now tends to be smoked, rather than air-dried, and typically comes in jars. But to my mind, chipped beef still counts as a survival from pioneer days, when midwestern and western settlers fried jerky in little shreds until it began to curl at the edges. The technical term for this is "frizzling." Once cooked in this way, or reconstituted through boiling, the beef could be combined with a whole range of foods, mostly starch or vegetables, to give them a protein boost and a crunchy, salty taste.

All through this hemisphere, cooks have done much the same thing with beef jerky. In Brazil, for instance, jerky shreds are mixed with toasted manioc or cornmeal (see recipe). And the national dish of Brazil, that black bean feast called feijoada, canonically includes jerky (*xarque* or *carne seca* in Portuguese) along with various smoked meats and pork oddments.

Jerky is native to Latin America. The word itself derives from *charqui*, the Quechua name for air-dried meat. One imagines that Spanish explorers discovered it when they conquered the Quechua-speaking Incas of the Andes, adopted the word (which is still current in Spanish), and exported the process to the American Southwest.

To this day, in Latin America, people jerk most available meats, not only beef and pork but also the rhea, an ostrich-like bird of the Argentine pampas, and the guanaco, a cameloid relative of the llama, whose flesh is said to resemble veal in taste. Guanaco is particularly prized in the extreme south of South America, where, reportedly, the meat of tough older animals is considered especially desirable when jerked and permitted to go slightly rancid.

In the West Indies, jerked beef also has an honorable history. The French colonizers called it *boucan*, the source of our word *buccaneer*, presumably because the pirates of the Antilles found jerked beef a convenience food in their fast-moving, homeless way of life. In official French, the original Quechua word survives as *charquer*, "to air dry meat." Probably it came into the French language as a result of New World contact between Spanish and French colonists.

It appears, then, that throughout the Western Hemisphere in the age of exploration, jerky was a meat that everyone ate. It was the most primitive and therefore the most appropriate form of cured meat. Today, when we continue to eat more technologically sophisticated preserved meats—corned beef, pastrami, and smoked ham—because we like their taste, we should probably pay just as much attention to jerky, the typical meat of the frontier and an estimable alternative, even in the computer age, to a hamburger.

Raymond Sokolov's new book, Fading Feasts *(Farrar Straus and Giroux), is a collection of food columns that first appeared in* Natural History.

Paçoca de Carne Seca

(Adapted from *Brazilian Cookery, Traditional and Modern*, by Margarette de Andrade)

- 1 pound jerked beef
- 2 tablespoons bacon fat
- 1 tablespoon butter
- 1 grated onion
- Salt
- Malagueta pepper (or cayenne)
- 1½ cups toasted manioc meal or cornmeal

1. Cut meat in pieces, trim off excess fat, and wash well. Soak overnight in cold water.
2. Next morning, hold under running cold water, then dry.
3. Heat bacon fat and butter in a heavy skillet. Sauté onion until it begins to brown. Then add meat pieces and cook over low heat. Stir with a fork, adding a few drops of boiling water from time to time as liquid evaporates. When the meat is brown and tender and almost dry, add salt and chopped malagueta pepper (or cayenne) to taste. Turn into a mortar and pound the meat to fine shreds or chop in blender.
4. Add the manioc or cornmeal a little at a time, until the mixture is the consistency of bread crumbs. Serve immediately.

Yield: 4–6 servings

WE'RE EXXON

We're Bob Payne, turning solid coal into a new source of liquid fuel for America.

America has more energy in coal than the Middle East has in oil. For many uses, however, the coal must be turned into a liquid. Bob Payne is using his 30 years of experience in petroleum refining to do something about that. He manages a test plant that's finding better ways to turn American coal into liquid products we can use in industry, homes and transportation.

The test program will cost $350 million. In addition to Exxon, it's funded by the U.S. Department of Energy, the Electric Power Research Institute, two other U.S. oil companies and companies from Japan, Germany and Italy.

The test plant uses the Exxon Donor Solvent Process which works on many different kinds of coal. It turns 250 tons of coal a day into a liquid that's a substitute for products made from natural crude oil.

Bob Payne and the scores of Exxon people at the test plant know their work is important, because coal is an alternative to foreign oil. It's one more way to produce energy in America, for America.

We're more than 100,000 people working on energy.

Authors

A clinical psychologist in private practice, a free-lance writer and photographer, a charter-boat operator, and a commercial fisherman, **James W. Greenough** may best be described as an inveterate whale watcher. The waters off the coast of southeastern Alaska provide him with ample opportunities to pursue the last activity. His professional research is on high-risk human health behaviors in Alaska. When not engaged with that project, he gardens, not too successfully, in the back of his home in Juneau.

An architect with the firm of Martin/Soderstrom/Matteson in Portland, Oregon, for twenty years, **Willard K. Martin** has been a student and practitioner of the art of watercolor for even longer—thirty years. Curiosity about plants, especially seed pod forms and dispersal mechanisms, combined with a love of travel, has taken him to "many parts of the world to search for and record unusual varieties of seed dispersal methods." Selections of Martin's paintings appeared in the April 1978 issue of *Natural History* ("Seeds in Flight") and in the June–July 1973 issue ("Seeds: Carriers of Life").

During a recent sabbatical, **John Alcock** hied himself to Australia to investigate a group of wasps he had read about. In Wyperfeld National Park, he met up with his quarry: thynnine wasps. The male wasps feed their mates before, during, and after copulation; feeding varies by species. Alcock determined to find out why they do so, rather than copulate and run as so many other male insects do. An associate professor of zoology at Arizona State University, Alcock's research has been on insect reproductive behavior, with a primary interest in the evolution of diversity in insect mating systems. His major diversion is a backyard garden in which, he claims, he grows an unrivaled crop of swiss chard.

Agassiz in the Galápagos

Why did the last great scientist-creationist retrace Darwin's footsteps?

by Stephen Jay Gould

I once had a gutsy English teacher who used a drugstore paperback called *Word Power Made Easy* instead of the insipid fare officially available. It contained some nifty words, and she would call upon us in turn for definitions. I will never forget the spectacle of five kids in a row denying that they knew what "nymphomania" meant—the single word, one may be confident, that everyone had learned with avidity. Sixth in line was the class innocent; she blushed and then gave a straightforward, accurate definition in her sweet, level voice. Bless her for all of us and our cowardly discomfort; I trust that all has gone well for her since last we met on graduation day.

Nymphomania titillated me to my pubescent core, but two paired words from the same lesson—anachronism and incongruity—interested me more for the eerie feeling they inspired. Nothing elicits a greater mixture of fascination and distress in me than objects or people that seem to be in the wrong time or place. The *little* things that offend a sense of order are the most disturbing. Thus, I was stunned in 1965 to discover that Alexander Kerensky, alive, well, and living as a Russian émigré in New York, had just written a book. Kerensky, the man who preceded the Bolsheviks in 1917? Kerensky, so linked with Lenin and times long past in my thoughts, still among us? (He died, in fact, in 1970, at age 89.)

Last month, on a ship headed for the Galápagos Islands, I encountered an incongruity that struck me just as forcefully. I was listening to a lecture when a throwaway line cut right into me. "Louis Agassiz," the man said, "visited the Galápagos and made scientific collections there in 1872." What? The primal creationist, the last great holdout against Darwin, in the Galápagos, the land that stands for evolution and prompted Darwin's own conversion? One might as well let a Christian into Mecca. It seems as incongruous as a president of the United States portraying an inebriated pitcher in the 1926 World Series.

Louis Agassiz was, without doubt, the greatest and most influential naturalist of nineteenth-century America. A Swiss by birth, he was the first great European theorist in biology to make America his home. He had charm, wit, and connections aplenty, and he took the Boston Brahmins by storm. He was an intimate of Emerson, Longfellow, and anyone who really mattered in America's most patrician town. He published and raised money with equal zeal and virtually established natural history as a professional discipline in America; indeed, I am writing this article in the great museum that he built.

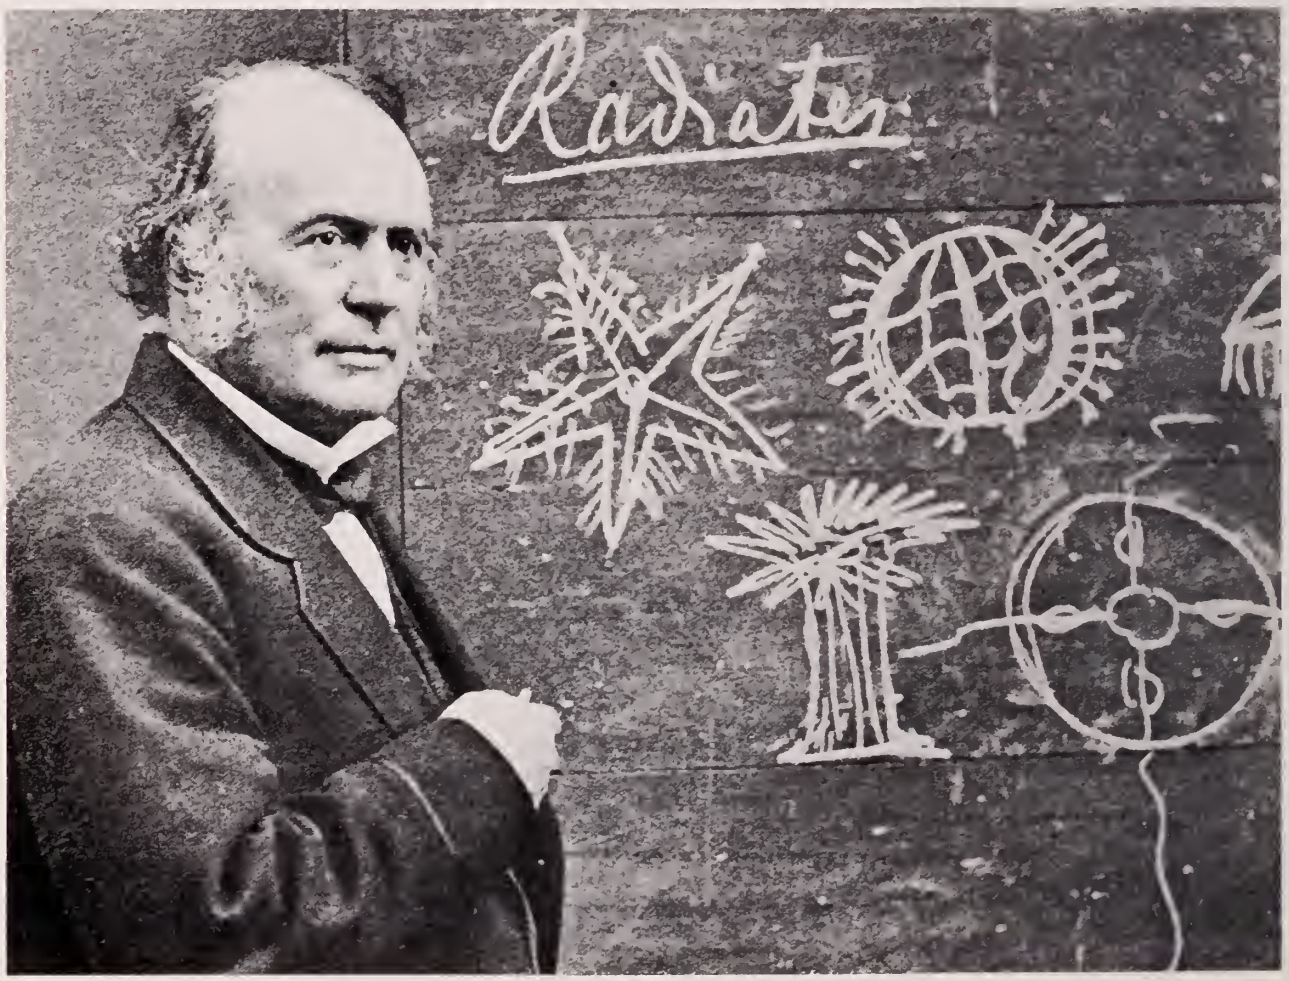
But Agassiz's summer of fame and fortune turned into a winter of doubt and befuddlement. He was Darwin's contemporary (two years older), but his mind was indentured to the creationist world view and the idealist philosophy that he had learned from Europe's great scientists. The erudition that had so charmed America's rustics became his undoing; Agassiz could not adjust to Darwin's world. All his students and colleagues became evolutionists. He fretted and struggled, for no one enjoys being an intellectual outcast. Agassiz died in 1873, sad and intellectually isolated but still arguing that the history of life reflects a preordained, divine plan and that species are the created incarnations of ideas in God's mind.

Agassiz did, however, visit the Galápagos a year before he died. My previous ignorance of this incongruity is at least partly excusable, for he never breathed a word about it in any speech or publication. Why this silence, when his last year is full of documents and pronouncements? Why was he there? What impact did those finches and tortoises have upon him? Did the land that so inspired Darwin, fueling his transition from prospective preacher to evolutionary agnostic, do nothing for Agassiz? Is not this silence as curious as the basic fact of Agassiz's visit? These questions bothered me throughout my stay in the Galápagos, but I could not learn the answers until I returned to the library that Agassiz himself had founded more than a century ago.

Agassiz's friend Benjamin Peirce had become Superintendent of the Coast Survey. In February of 1871, he wrote to Agassiz offering him the use of the *Hassler*, a steamer fit for deep-sea dredging. I suspect that Peirce had a strong ulterior motive beyond the desire to collect some deep-sea fishes: he hoped that Agassiz's intellectual stagnation might be broken by a long voyage of direct exposure to nature. Agassiz had spent so much time raising money for his museum and politicking for natural history in America that his contact with organisms other than the human kind had virtually ceased. Agassiz's life now belied his famous motto: study nature, not books. Perhaps he could be shaken into modernity by renewed contact with the original source of his fame.

Agassiz understood only too well and readily accepted Peirce's offer. Agassiz's friends rejoiced, for all were saddened by the intellectual hardening of such a great mind. Darwin himself wrote to Agassiz's son: "Pray give my most sincere respects to your father. What a wonderful man he is to think of going round Cape Horn; if he does go, I wish he could go through the Strait of Magellan." The *Hassler* left Boston in December 1871, moved down the eastern coast of South America, fulfilled Darwin's hope by sailing through the Strait of Magellan, passed up the west-

ern coast of South America, reached the Galápagos (at the Equator, 600 miles off the coast of Ecuador) on June 10, 1872, and finally docked at San Francisco on August 24.



A possible solution to the enigma of Agassiz's silence immediately suggests itself. The Galápagos are pretty much "on the way" along Agassiz's route. Perhaps the *Hassler* only stopped for provisions—just passing by. Perhaps the cruise was so devoted to deep-sea dredging and Agassiz's observations of glaciers in the southern Andes that the Galápagos provided no special interest or concern.

This easy explanation is clearly incorrect. In fact, Agassiz planned the *Hassler* voyage as a test of evolutionary theory. The dredging itself was not designed merely to collect unknown creatures but to gather evidence that Agassiz hoped would establish the continuing intellectual validity of his lingering creationism. In a remarkable letter to Peirce, written just two days before the *Hassler* set sail, Agassiz stated exactly what he expected to find in the deep dredges.

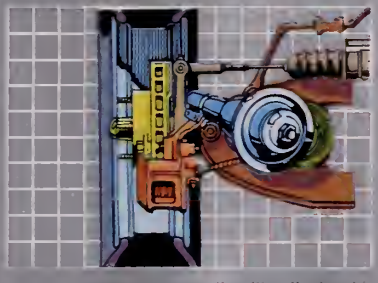
Agassiz believed that God had ordained a plan for the history of life at the beginning and then proceeded to create species in the appropriate sequence throughout geological time. God matched environments to the preconceived plan of creation. The fit of life to environment does not record the evolutionary tracking of changing climates by organisms but rather the construction of environments by God to fit the preconceived plan of creation: "the animal world designed from the beginning has been the motive for the physical changes which our globe has undergone," Agassiz wrote to Peirce. He then applied this curiously inverted argument to the belief, then widespread but now disproved, that the deep oceans formed a domain devoid of change or challenge—a cold, calm, and constant world. God could only have made such an environment for the most primitive creatures of any group. The deep oceans would therefore harbor living representatives of the simple organisms found fossil in ancient rocks. Since evolution demands progressive change through time, the persistence of these simple and early forms will demonstrate the bankruptcy of Darwinian theory. (I don't think Agassiz ever understood that the principle of natural selection does not predict global and inexorable progress but only adaptation to local environments. The persistence of simple forms in a constant deep sea would have satisfied Darwin's evolutionary theory as well as Agassiz's God. But the depths are not constant, and their life is not primitive.)

The letter to Peirce displays that mixture of psychological distress and intellectual pugnacity so characteristic of Agassiz's opposition to evolution in his later years. He knows that the world will scoff at his preconceptions, but he will pursue them to the point of specific predictions nonetheless—the discovery of "ancient" organisms alive in the deep sea:

> I am desirous to leave in your hands a document which may be very compromising for me, but which I nevertheless am determined to write in the hope of showing within what limits natural history has advanced toward that point of maturity when

Until his death in 1873, Louis Agassiz argued against the theory of evolution. AMNH

FORD MUSTANG



From simmer to sizzle.

Whether you choose the simmer of Mustang L or the sizzle of Mustang GT, you can be sure of one thing: excitement is not far behind.*

Your kind of sizzle.

Inside Mustang's slick aerodynamic shape lives a finely engineered power plant. Choose from the standard 2.3 liter 4-cylinder with optional 5-speed transmission, all the way up to the 5.0 liter High-Output engine, that's designed and built to be a performer. Coupled with Mustang's standard rack and pinion steering and modified MacPherson strut suspension—we've got your performance needs covered.

*Mustang model availability limited in some states. See your dealer for details.

Options. Whatever you choose, you're going to be right.

Inside Mustang you'll find impressive comfort and convenience. Maybe you'll go for the leather-wrapped steering wheel surrounded by an easy-to-read instrument cluster. Or maybe you'll turn up the heat with an AM/FM stereo radio with cassette tape, coupled with Ford's Premium Sound System, then choose air conditioning to cool things down. But whatever you choose you're going to be right.

We've got you covered for good mileage.

Mustang is aerodynamically designed to move freely through the streets while squeezing every drop of fun out of a gallon of gas.

33 EST HWY **22** EPA EST MPG

For comparison. Your mileage may differ depending on speed, distance and weather. Actual highway mileage lower.

And sometimes, we've even got you uncovered.

The optional T-Roof makes Mustang an excellent place to watch the world watch you back.

Whether you buy or lease, see Mustang at your Ford Dealer now.

science may anticipate the discovery of facts. If there is, as I believe to be the case, a plan according to which the affinities among animals and the order of their succession in time were determined from the beginning . . . if this world of ours is the work of intelligence, and not merely the product of force and matter, the human mind, as a part of the whole, should so chime with it, that, from what is known, it may reach the unknown.

But Agassiz did not sail only to test evolution in the abstract. He chose his route as a challenge to Darwin, for he virtually retraced—and by conscious choice—the primary part of the *Beagle*'s itinerary. The Galápagos were not a convenient way station but a central part of the plot. His later silence becomes more curious.

The *Beagle* did circumnavigate the globe, but Darwin's voyage was basically a surveying expedition of the South American coast. Agassiz's route therefore retraced the essence of Darwin's pathway—physically if not intellectually. One cannot read Elizabeth Agassiz's account of the *Hassler* expedition (published in her official biography of her husband) without recognizing the uncanny (and obviously not accidental) similarity with Darwin's famous account of the *Beagle*'s voyage. (Elizabeth accompanied Louis on the trip.) Darwin concentrated primarily upon geology and so did Agassiz. The trip may have been advertised as a dredging expedition, but Agassiz was most interested in reaching southern South America to test his theory of a global ice age. He had studied glacial striations and moraines in the Northern Hemisphere and had determined that a great ice sheet has descended from the north. (Striations are scratches on bedrock made by pebbles frozen into the bases of glaciers. Moraines are hills of debris pushed by flowing ice to the fronts and sides of glaciers.) If the ice age had been global, striations and moraines in South America would indicate a spread from Antarctica at the same time. Agassiz's predictions were, in this case, upheld—and he exulted in copious print (faithfully transcribed by Elizabeth and published in the *Atlantic Monthly*).

Darwin was appalled by the rude life and appearance of the "savage" Fuegians and so was Agassiz. Elizabeth recorded their joint impressions: "Nothing could be more coarse and repulsive than their appearance, in which the brutality of the savage was in no way redeemed by physical strength or manliness. . . . They scrambled and snatched fiercely, like wild animals, for whatever they could catch."

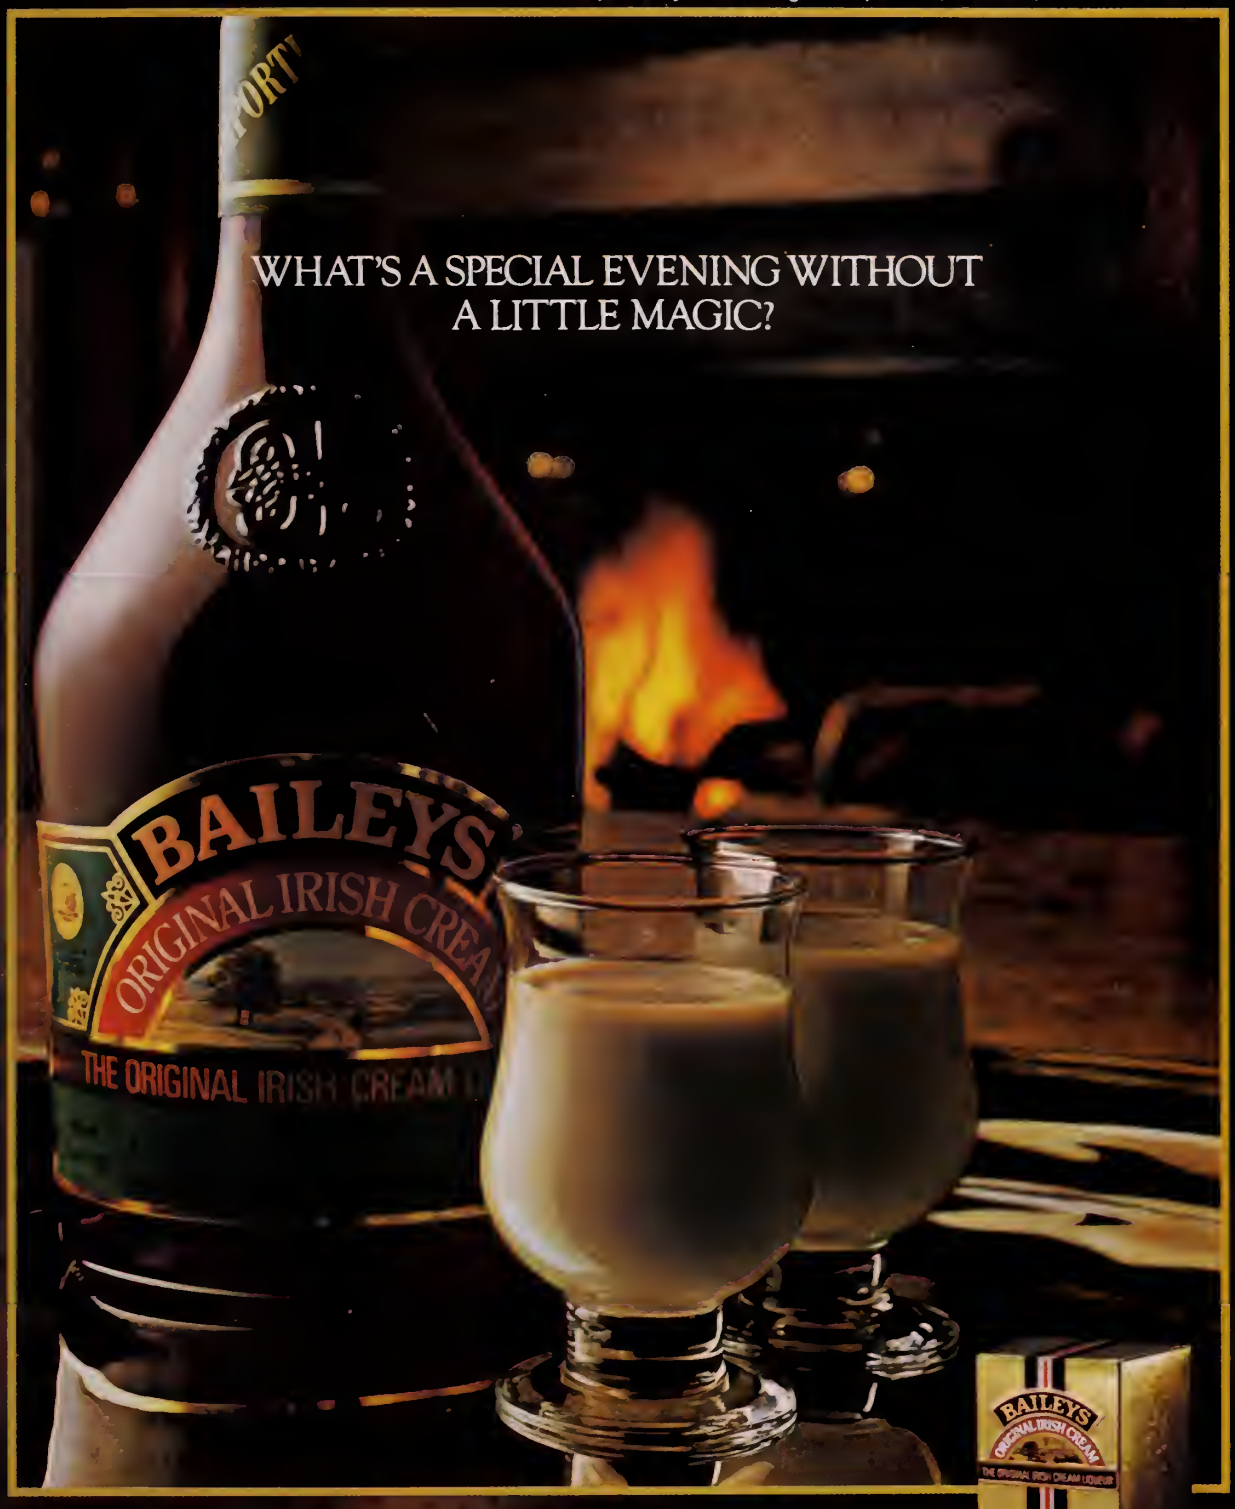
If there be any lingering doubt about Agassiz's conscious decision to evaluate Darwin by retracing his experiences, consider this passage, written at sea to his German colleague Carl Gegenbaur:

I have sailed across the Atlantic Ocean through the Strait of Magellan, and along the western coast of South America to the northern latitudes. Marine animals were, naturally, my primary concern, but I also had a special purpose. I wanted to study the entire Darwinian theory, free from all external influences and former surroundings. Was it not on a similar voyage that Darwin developed his present opinions! I took few books with me . . . primarily Darwin's major works.

I can find few details about Agassiz's stay in the Galápagos. We know that he arrived on June 10, 1872, spent a week or more, and visited five islands, one more than Darwin did. Elizabeth claims that Louis "enjoyed extremely his cruise among these islands of such rare geological and zoological interest." We know that he collected (or rather sat on the rocks while his assistants gathered) the famous iguanas that go swimming in the ocean to eat marine algae (some of his specimens are still in glass jars in our museum). We know that he crossed and greatly admired the bare fields of recently cooled ropy lava "full of the most singular and fantastic details." I walked across a similar field, which Agassiz could not have seen since it formed during the 1890s. I was mesmerized by the frozen signs of former activity—the undulating, ropy patterns of flow, the burst bubbles, and lengthy cracks of contraction. And I saw Pele's tears, the most beautiful geological object, at small scale, that I have ever witnessed. When highly liquid lava is ejected from small vents, it may emerge as droplets of basalt that build drip castles of iridescent stone about their outlet—tears from Pele, the Hawaiian goddess of volcanoes (not from Martinique's Mount Pelée, which has an extra *e*).

Thus, I return to my original inquiry: if Agassiz went to the Galápagos as a central part of his plan to evaluate evolution by putting himself in Darwin's shoes, what effect did Darwin's most important spot have upon him? In response to this question we have only Agassiz's public silence (and one private communication, to which I will shortly return).

Two nonintellectual reasons may partly explain Agassiz's uncharacteristic reticence. First, despite his productive observations on South American glaciers, the *Hassler* expedition was basically a failure and a profound disappointment—and Agassiz may have chosen largely to forget about it. The dredging equipment never worked properly, and Agassiz recovered no specimens from the deepest oceans. The crew tried its best, but the ship was a misery. Jules Marcou, Agassiz's faithful biographer, wrote: "It was a great, almost a cruel, carelessness to embark a man so distinguished, so old [Agassiz was 64; perhaps concepts of age have changed], and so much an invalid as Agassiz was, in an unseaworthy craft, sailing under the United States flag."



Secondly, Agassiz was ill during much of the voyage, and his listlessness and discomfort increased as he left his beloved southern glaciers and moved into the sultry tropics. (The Galápagos, however, despite their equatorial location, lie in the path of a cool oceanic current and are generally temperate; the northernmost species of penguin inhabits its shores.) Shortly after his return to Harvard, Agassiz wrote to Pedro II, emperor of Brazil (and an old buddy from a previous voyage):

When I traversed the Strait of Magellan . . . work again became easy for me. The beauty of its sites, the resemblance of the mountains to those of Switzerland, the interest that the glaciers awakened in me, the happiness in seeing my predictions affirmed beyond all my hopes—all these conspired to set me on the right course again, even to rejuvenate me. . . . Afterwards, I gradually declined as we advanced towards the tropical regions; the heat exhausted me greatly, and during the month that we spent in Panama I was quite incapable of the least effort.

(For all citations from letters, I have relied upon the originals in Harvard's Houghton Library; none have been published in full before, although several have been excerpted in print. Agassiz wrote with equal facility in French [to Pedro II], German [to Gegenbaur], and English [to Peirce], and I have supplied the translations. I thank my secretary Agnes Pilot for transcribing the Gegenbaur letter into sensible Roman. Agassiz wrote it in the old German script that is all squiggles to me.)

So far as I can tell, Agassiz's only statement about the Galápagos occurs in a private letter to Benjamin Peirce, composed at sea on July 29, 1872, the day after he had written to Gegenbaur (and said nothing about the Galápagos). The letter begins with the lament of all landlubbers: "I fancy this note may

Baileys. A unique taste so silken, so full of character, only one word can describe it. Magic.

Perhaps it's that taste of magic that has made Baileys America's fastest growing liqueur.

BAILEYS. TASTE THE MAGIC.

reach you in Martha's Vineyard, and I heartily wish I could be there with you, and take some rest from this everlasting rocking." Agassiz continues with his only statement:

Our visit to the Galapagos has been full of geological and zoological interest. It is most impressive to see an extensive archipelago, of most recent origin, inhabited by creatures so different from any known in other parts of the world. Here we have a positive limit to the length of time that may have been granted for the transformation of these animals, if indeed they are in any way derived from others dwelling in different parts of the world. The Galapagos are so recent that some of the islands are barely covered with the most scanty vegetation, itself peculiar to these islands. Some parts of their surface are entirely bare, and a great many of the craters and lava streams are so fresh, that the atmospheric agents have not yet made an impression on them. Their age does not, therefore, go back to earlier geological periods; they belong to our times, geologically speaking; Whence, then, do their inhabitants (animals as well as plants) come? If descended from some other type, belonging to any neighboring land, then it does not require such unspeakably long periods for the transformation of species as the modern advocates of trans-

Agassiz's friend Benjamin Peirce, right, arranged for his voyage to the Galâpagos.

The Granger Collection

WE'RE EXXON

We're Jay Stone, making waves in the search for oil.

Finding new oil is one of America's most difficult energy problems. Jay Stone has eased that problem by helping design high-tech trucks that carry unique seismic devices for vibrating the earth.

Unlike similar devices, these Broad Band Vibrators can send much more powerful seismic waves into the ground. And give us a more accurate picture of the rock structures that lie beneath the earth's surface.

By studying charts of the returning echoes, Exxon's explorers can find the areas most likely to harbor oil, and determine the best sites for drilling wells.

Jay Stone's work on Exxon's seismic trucks is helping America reduce its chance of coming up dry in the search for oil and gas. And Stone is just one of thousands of Exxon people who are extending America's reach for American energy.

We're more than 100,000 people working on energy.

EXXON

mutation claim; and the mystery of change, with such marked and characteristic differences between existing species, is only increased, and brought to level with that of creation. If they are autochthones, from what germs did they start into existence? I think that careful observers, in view of these facts, will have to acknowledge that our science is not yet ripe for a fair discussion of the origin of organized beings.

The quotation is long, but it is, so far as I know, exclusive. Its most remarkable aspect is an extreme weakness, almost speciousness, of argument. Agassiz makes but a single point: many animals of the Galápagos live nowhere else. Yet the islands are so young that a slow process of evolution could not have transformed them from related ancestors in the time available. Thus, they were created where we find them (the obvious bottom line, despite Agassiz's final disclaimer that we know too little to reach any firm conclusion).

Two problems: First, although the Galápagos are young (two to five million years for the oldest islands by current reckoning), they are not so pristine as Agassiz indicates. In the letter, Agassiz describes lava flows of the past hundred years or so, and these are virtually devoid of vegetation and so fresh that one can almost see the flow and feel the heat. But Agassiz surely knew that several of the islands (including some on his itinerary) are more densely vegetated and, although not ancient, were surely not formed in a geological yesterday.

Second, Agassiz leaves out the most important aspect of Darwin's argument. The point is not that so many species of the Galápagos are unique but rather that their nearest relatives are invariably found on the adjacent South American mainland. If God created the Galápagos species where we find them, why did he imbue them with signs of South American affinity (especially since the temperate climates and lava habitats of the Galápagos are so different from the tropical environments of the ancestral forms). What sense can such a pattern make unless the Galapagian species are modified descendants of South American forms that managed to cross the oceanic barrier? Darwin wrote in the *Voyage of the Beagle*:

> Why, on these small points of land, which within a late geological period must have been covered by the ocean, which are formed by basaltic lava, and therefore differ in geological character from the American continent, and which are placed under a peculiar climate,—why were their aboriginal inhabitats . . . created on American types of organization.

And the famous, poetic statement earlier in the chapter: "We seem to be brought somewhat near to the great fact—that mystery of mysteries—the first appearance of new beings on this earth."

Agassiz could not have misunderstood, for, like Darwin, he was a professional biogeographer who, unlike Darwin, had used arguments of geographical distribution as his primary defense for creationism. Why did he skirt Darwin's principal argument? Why did he say so little about the Galápagos and argue so poorly?

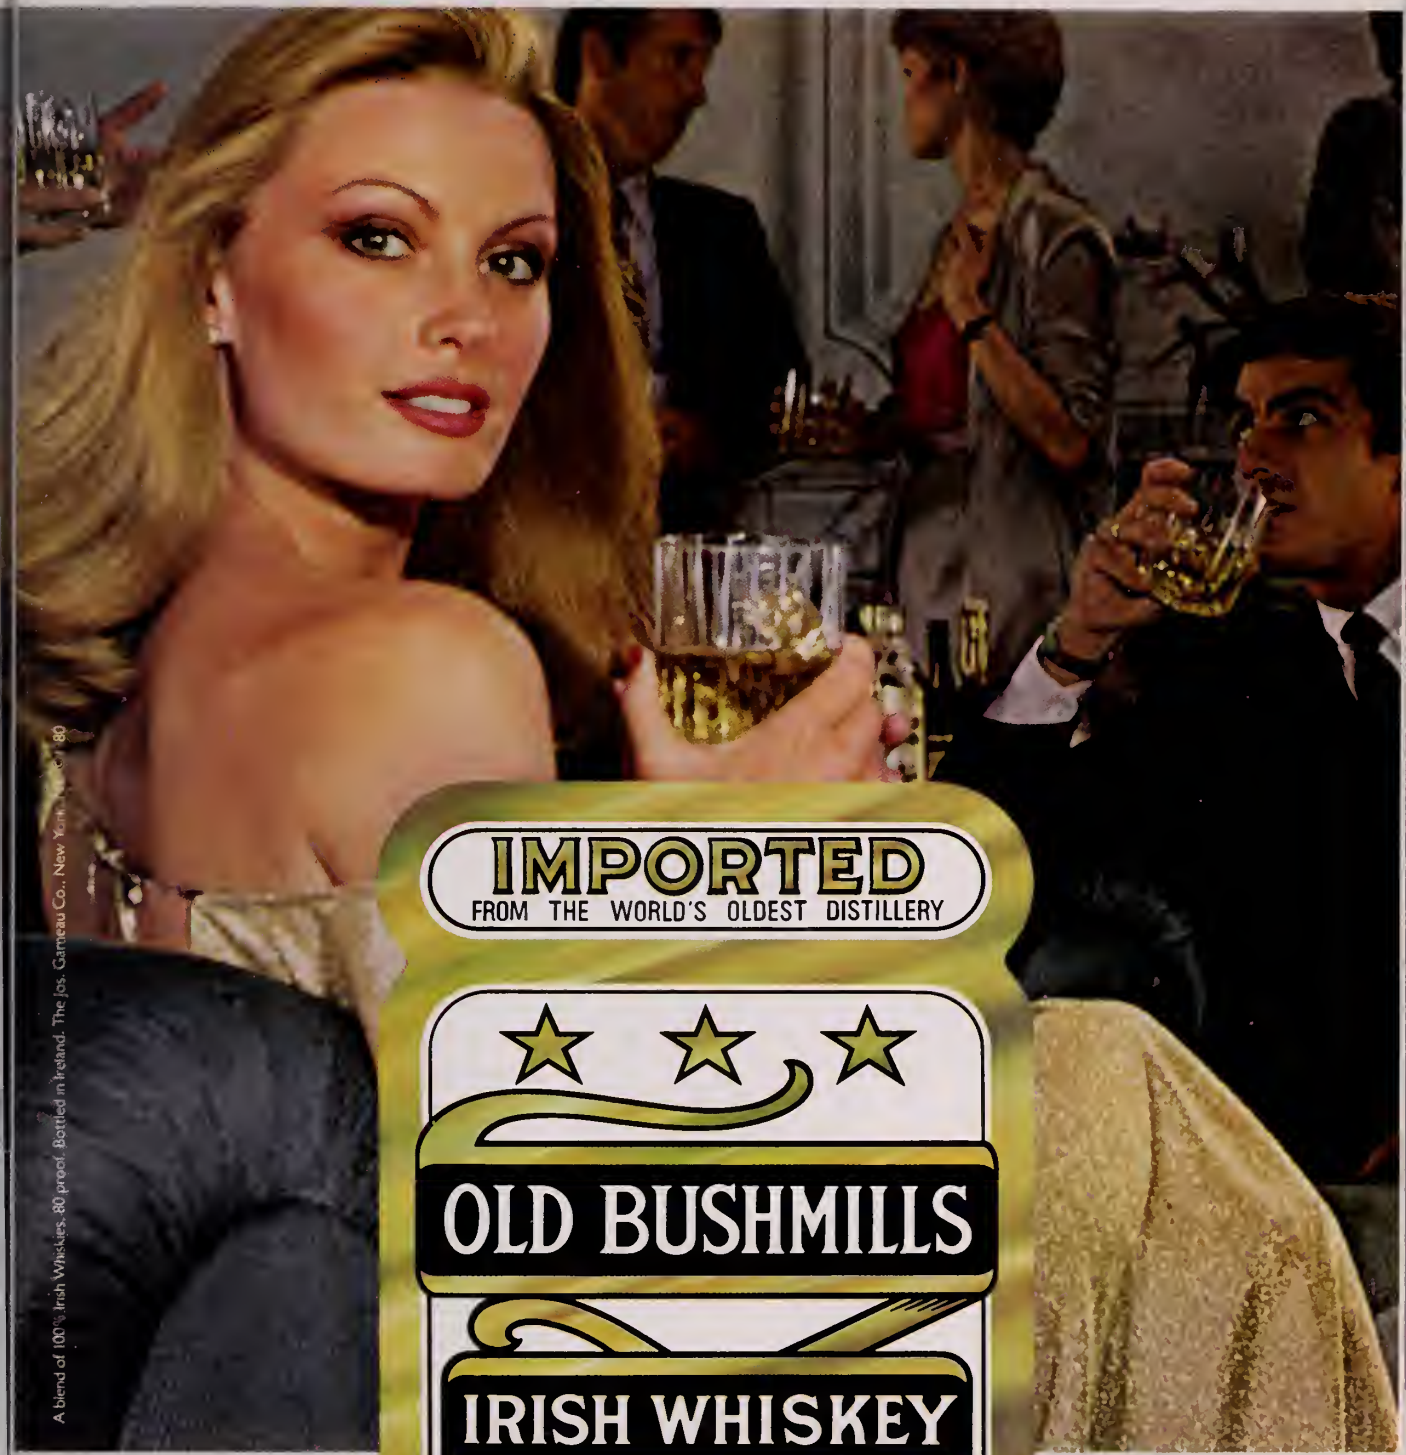
I think that we must consider two possibilities as resolutions to the conundrum of Agassiz's silence (or failure to consider the critical points in his one private statement). Perhaps he knew that his argument to Peirce was hokey and inadequate. Perhaps the Galápagos, and the entire *Hassler* voyage, had produced the same change of heart that Darwin had experienced in similar circumstances and Agassiz simply couldn't muster the courage to admit it.

I cannot accept such a resolution. As I said earlier, we see abundant signs of psychological distress and deep sadness in Agassiz's last defenses of creationism. No one enjoys being an intellectual outcast, especially when cast in the role of superannuated fuddy-duddy (the part of ignored but prophetic seer at least elicits moral courage). Yet, however weak his arguments (and they deteriorated as the evidence for evolution accumulated), I sense no failure of Agassiz's resolve. The letter to Peirce seems to represent still another of Agassiz's flawed, but perfectly sincere, defenses of an increasingly indefensible, yet steadfastly maintained, view of life. (Agassiz's last article, posthumously published in the *Atlantic Monthly* in 1874, was a ringing apologia for creationism entitled: "Evolution and Permanence of Type.")

I think that we must accept the second resolution: Agassiz said so little about the Galápagos because his visit made preciously little impact upon him. The message is familiar but profound nonetheless. Scientific discovery is not a one-way transfer of information from unambiguous nature to minds that are always open. It is a reciprocal interaction between a multifarious and confusing nature and a mind sufficiently receptive (as many are not) to extract a weak but sensible pattern from the prevailing noise. There are no signs on the Galápagos that proclaim: Evolution at work. Open your eyes and ye shall see it. Evolution is an inescapable inference, not a raw datum. Darwin, young, restless, and searching, was receptive to the signal. Agassiz, committed and defensive, was not. Had he not already announced in the first letter to Peirce that he knew what he must find? I do not think he was free to reach Darwin's conclusions, and the Galápagos Islands, therefore, carried no important message for him. Science is a balanced interaction of mind and nature.

Agassiz lived for little more than a year after the *Hassler* docked. James Russell Lowell, traveling abroad, learned of his friend's death from a newspaper and wrote in poetic tribute (quoted from E. Lurie's fine biography of Agassiz, *Louis Agassiz: A Life in Science*, University of Chicago Press, 1960):

> . . . with vague, mechanic eyes,
> I scanned the festering news we half despise
> When suddenly,
> As happens if the brain, from overweight
> Of blood, infect the eye,
> Three tiny words grew lurid as I read,
> And reeled commingling: Agassiz is dead!



I do not know. Perhaps a bit of his incorporeal self went up to a higher realm, as some religions assert. Perhaps he saw there old Adam Sedgwick, the great British geologist (and reverend), who at age 87 wrote to Agassiz a year before the *Hassler* sailed:

> It will never be my happiness to see your face again in this world. But let me, as a Christian man, hope that we may meet hereafter in heaven, and see such visions of God's glory in the moral and material universe, as shall reduce to a mere germ everything which has been elaborated by the skill of man.

Be that as it may, Agassiz's ideas had suffered an intellectual death before he ever reached the Galápagos. Life is a series of trades. We have lost the comfort of Agassiz's belief that a superior intelligence directly regulates every step of life's history according to a plan that places us above all other creatures. ("If it had been otherwise," Agassiz wrote to Pedro II in June 1873, "there would be nothing but despair.") We have found a message in the animals and plants of the Galápagos, and all other places, that enables us to appreciate them, not as disconnected bits of wonder, but as integrated products of a satisfactory and general theory of life's history. That, to me at least, is a good trade.

Stephen Jay Gould teaches biology, geology, and the history of science at Harvard University.

Early Bird Photographers

Seventy-five years ago, two young men braved storms, cliffs, and mosquitoes to photograph birds—and sometimes themselves

by Worth Mathewson and Margaret Thompson Mathewson

To the student of nature of three generations ago, the names of William L. Finley and Herman T. Bohlman were instantly recognizable. Today, Bohlman is almost entirely forgotten, and save for the William L. Finley National Wildlife Refuge south of Corvallis, Oregon, and a rather obscure memorial marker at the edge of a vast desert marsh named Malheur in southeastern Oregon, Finley's name too has faded from the public memory. Their contributions to the young art of bird photography, however, and Finley's efforts on behalf of conservation both in his home state of Oregon and on the national level should have earned them a permanent place in the minds of all interested in natural history and concerned with the preservation of wildlife.

Finley and Bohlman were boyhood friends in Portland in the last quarter of the nineteenth century. Bohlman had a camera and Finley an interest in birds. During the years 1898 to 1912, they worked closely together on several photography projects that gained fame for Finley and that, by calling the attention of the American public and Pres. Theodore Roosevelt to the plight of our native birds, advanced the cause of wildlife protection. Finley came to be known as a dedicated conservationist through photographs (produced first in collaboration with Bohlman and later on his own), writings, films, and political activities. Bohlman (who went on to become a plumber and a landscape painter) never achieved the national recognition that Finley enjoyed for most of his life, but the excellent photographs of the early period were clearly the result

AMERICAN MUSEUM OF NATURAL HISTORY
Vacations on sea and land with Museum Lecturers

NILE CRUISE: Explore the astounding ancient sites and natural wonders of Egypt with a Museum geologist, ornithologist illustrator, and Egyptologist. Cruise 600 miles on the Nile from Cairo to Assuan aboard the custom-built, air-conditioned *Nile Star* stopping at all the important sites which have intrigued visitors since their construction.

INDONESIAN ODYSSEY: Cruise through the paradise islands of Bali, Java, Komodo, Sulawesi, Lombok, Flores, Butung, the Moluccas and Luciparas aboard the luxury vessel, *Regina Maris*. Share with a Museum astronomer, anthropologist, ornithologist, geologist/volcanologist, and herpetologist a unique, in-depth travel experience. The itinerary takes you to lush tropical landscapes with exotic peoples influenced for centuries by India, Islam and Europe.

GALAPAGOS ISLANDS CRUISE: Discover a special natural world with fantastically tame and exotic animals such as sea lions, giant tortoises, marine and land iguanas and countless rare and beautiful birds. Enjoy the expertise of a Museum ornithologist and herpetologist and four local naturalists as we cruise through this equatorial archipelago which so influenced Darwin.

ADRIATIC AND AEGEAN ADVENTURE: Relive the great historical travels of the Greeks, Romans, Phoenicians and Venetians. Follow their paths on a classical cruise starting in Venice and going to Dubrovnik, Corfu, Corinth, Crete, Rhodes, Tunis, Carthage, Malta, Sicily, Pompeii, Herculaneum and Naples. The *Orpheus* will be your home for 14 beautiful days; the Museum faculty will be outstanding.

LAND PROGRAMS: Seven outstanding overland itineraries have been custom-designed for small groups of 15-25 participants. Famous and remote sites and cultures are discovered while staying at the finest accommodations available with expert Museum Lecturers.

DESTINATION	1982 Dates
Archeology Tour to Mexico	January 11 to 29

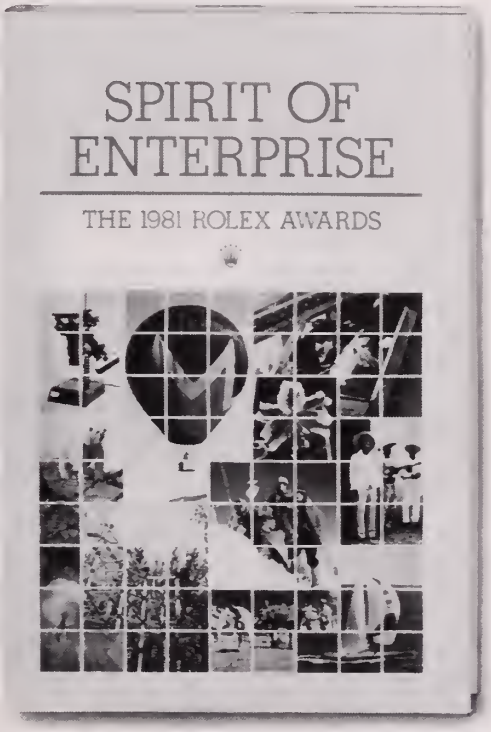
of joint effort. Indeed, some people familiar with the team's work believe that during this time Bohlman was actually the more skilled artist.

According to Finley, the pair's first photography ventures of "any consequence" took place in the Pacific Northwest on canoe trips in the summers of 1897, 1898, and 1899. During these years, the two men established their method of working together, generally making exhaustive life histories of the birds they photographed. The first such project, and one that proved remunerative, focused on a pair of red-tailed hawks nesting in a cottonwood tree 120 feet above the Columbia River. Finley and Bohlman found the nesting area in 1898, located the actual nest in 1899, and finally accomplished the difficult climb up to the nest in 1900. Over the course of a month, they took a large number of photographs. Some, along with an article, were sold to *Country Life in America.*

The rest of the decade continued to be

In Portland, Oregon, Finley and Bohlman (with moustache) posed with flickers in 1901, below. Two years later, they scaled sheer cliffs, right, to reach sea bird nesting grounds on Three Arch Rocks, large basalt formations off the Oregon coast.



productive for Finley and Bohlman. In 1901, on their first serious photography trek out of the Portland area, they arranged for sea lion bounty hunters to ferry them out to Three Arch Rocks, three looming basalt formations that lie a mile off the north Oregon coast and are the nesting grounds of vast colonies of sea birds. The 1901 visit was short and produced few good photographs, but they returned early in the summer of 1903, equipped with boat, tent, and food for an extended stay. Rough weather forced them to camp on the beach for more than two weeks before wave action subsided sufficiently to allow them to reach the rocks, where they encountered great numbers of common murre, pigeon guillemot, tufted puffin, western gull, three species of cormorant, and two species of petrel. Photographing the birds required considerable agility and strength. For example, to reach a murre colony the men had to scale a sheer rock face, heavy camera gear in hand.

The next summer, Finley and Bohlman pursued golden eagles, great blue herons, and night herons in California. Earlier efforts to photograph herons in a rookery near Portland had met with only limited success because the nests were high up in tall firs. Of this experience, Finley wrote:

> The photographer had selected the most "climbable-looking" stronghold in the heronry, where the nearest tree was a hundred and thirty feet up. But after the long, arduous ascent, he found that ... fifteen feet away in the branches of an adjoining tree was a nest containing four eggs. To get this, the photographer strapped himself

A book as unique as the watch itself.

The book is Spirit of Enterprise — The 1981 Rolex Awards. And the watch, of course, is Rolex.

Simply put, we asked the worldwide scientific community for ideas that challenge the mind and quicken the heart. Projects were submitted for consideration in three broad categories: Applied Sciences and Invention, Exploration and Discovery, and The Environment.

A distinguished international committee examined thousands of entries, and, after months of deliberation, conferred five Rolex Awards for Enterprise. The prize for each Award was 50,000 Swiss francs and a gold Rolex Chronometer.

Spirit of Enterprise details the winning projects, along with hundreds of unusual, imaginative and otherwise stimulating proposals for scientific investigation.

Everything from a method that just might get useful energy from magnetism to how to save the sperm whales by cultivating a desert plant.

The Rolex Awards for Enterprise celebrate the fertility of humankind's imagination. And the book makes worthwhile, exciting reading, particularly if you're the kind of person who appreciates the spirit of Rolex itself.

Spirit of Enterprise — The 1981 Rolex Awards isn't a book for everybody. But then again, Rolex isn't a watch for everybody, either.

ROLEX

*Spirit of Enterprise — The 1981 Rolex Awards, 460 pages, suggested list price, $15.95.**

carefully in the branches and wrapped his legs about the trunk. With a rope, he lassoed the broken end of a limb on the adjoining tree, and, by slipping the cord back and forth, worked the rope up to the trunk. A slow, steady pull and the tops of the trees bent closer together. The tension became stronger and stronger between the two trees, until at four feet it looked like a huge catapult that might suddenly be sprung and shoot the climber backward into space. In another instant an aerial bridge was formed in the treetop while the photographer secured his prize.

The California rookery was situated in sycamores, where nests were much more accessible. In a single tree, the two men counted forty-one blue heron nests and twenty-eight night heron nests. The photographs from this summer turned out well, but they were obtained at great personal suffering caused by thick

In 1904 the pair traveled to California, where they photographed golden eagles in the nest, right. While photographing herons, they were forced to sleep in a haystack, below, to escape hordes of mosquitoes.

stands of poison oak and mobs of mosquitoes. To escape the latter Finley and Bohlman slept in the dusty, prickly confines of a haystack.

In the spring of 1905 Finley and Bohlman traveled to Klamath Marsh in southeastern Oregon. Three years later, they visited Malheur Marsh, farther to the east at the base of steeply rising Steens Mountain. These were extended visits, each more than a month in length, and were not without hardships. The two men often slept on top of muskrat houses and were forced to deal with alkaline drinking water, hordes of insects, and sudden storms. At Klamath Lake, they landed on an island only to find it covered with fleas, and at Malheur they were lost for a full day and night in the towering tule reeds.

These two trips were taken partly at the urging of William Dutcher, president of the fledgling National Association of Audubon Societies. Dutcher wanted Finley and Bohlman to secure information and photographs for a report regarding the killing of egrets, grebes, terns, and other birds for the millinery trade. At this time, the widespread destruction of native birds for their plumage was coming increasingly under attack, and in 1910 *Atlantic*

AMERICA'S TRUCK. BUILT FORD TOUGH.

LION IN WINTER.

Bronco roars to the top nonstop. Its husky 4.9L (300) Six churns out more torque than any competitive Six. It also turns out excellent gas mileage ratings: 24 est. highway, (17) EPA est. mpg.*

Inside it's a real family 4-wheeler. There's room for six with front and rear bench seat options (front buckets are standard). But Bronco's trim outer size makes it easy to maneuver, fun to drive *wherever* you drive.

Underneath you'll find the only independent front suspension in an American-built sport utility. It's smooth *and* tough!

Mileage-boosting 4-speed overdrive, another Ford first, is optional. So are automatic locking hubs. They run free on the highway, lock in automatically when you shift to 4WD.

No other 4-wheeler offers all this. So why settle for less than Bronco—it's one beautiful beast!

*With std. 4.9L (300) Six and opt. 4-speed overdrive. Use for comparison. Your mileage may differ depending on speed, distance and weather. Actual highway mileage and California estimates lower.

Chivas Brothers make the world's finest Scotch.
And the same renowned Chivas quality and tradition goes into its equally-regal Lochan Ora Liqueur. With a unique taste all its own. Lochan Ora is to be lingered over—sipped slowly, savored fully. It's expensive but, then, good taste invariably is.

Lochan Ora.

The Imported Liqueur from Chivas Brothers.

70 PROOF • IMPORTED BY GENERAL WINE & SPIRITS CO., N.Y., N.Y.

Monthly published "The Trail of the Plume-Hunter," an influential article by Finley based largely on his Malheur experience. The photographs of waterfowl at Klamath and Malheur helped the Audubon cause and captured the attention of President Roosevelt, whose decision to establish the two marshes and Three Arch Rocks as federal wildlife refuges was influenced by Finley and Bohlman's work.

In 1906, between the two marsh studies, Finley embarked on the project that he and many others considered the most important of his long career. The naturalist Joseph Grinnell located a California condor's nest in the Sierra Madre Mountains and invited Finley to make a photographic study—the first done on the species, which was diminishing rapidly even then. Arriving at the nest in March within an hour or so after the young condor had hatched, Finley secured two good plates of the chick and mailed prints to Bohlman, who took three months off from work to join the expedition. In July, Finley took the young condor, which he had named General, back to Oregon and kept it at his home until the early fall; then he sent it by rail to William Hornaday, director of the New York Zoological Society.

The young condor did well for a number of years until it tragically succumbed to the effects of swallowing a rubber band.

The year 1906 also saw Finley's marriage to Irene Barhart. Finley and Bohlman worked closely together for the last time during the summer of 1912, when they revisited many of their old haunts; in subsequent years, Finley's fieldwork was primarily shared by his wife. The Finleys also wrote several books and numerous magazine articles together. For many years, Finley was a chief contributor to *Nature* magazine, which was incorporated into *Natural History* in the 1950s.

In his lifetime, Finley produced more than 50,000 still photographs (many with Bohlman) and 200,000 feet of motion picture film on various natural history subjects. His productivity was not limited, however, to photography and writing; Finley was also involved throughout his life in conservation activities. Among other appointments, Finley served as president of the Oregon Audubon Society, and vice-president of the Isaak Walton League of America and the National Wildlife Federation; he also established and headed, as state game warden, Oregon's Fish and Game Department. He spoke out perhaps most strongly for the protection of the waters and wildlife of his home state against the extremes of commercialism, but he also traveled across the country giving lectures on wildlife and conservation.

The respect with which he was looked upon is exemplified by the thoughts of the cartoonist and champion of conservation Jay Norwood ("Ding") Darling in a personal letter sent to Finley on his seventieth birthday: "Among all the friends with whom we have worked you have been the only one who was militant enough to suit me. Your vigor of statements and your vision matched the great objectives for which we fought." The photographs on these pages, which were taken in the days of close association with Bohlman, clearly show that Finley's commitment to conservation was equaled by his dedication to bird photography.

Worth Mathewson, a free-lance writer, has been a student of William Finley's life for twenty-five years. He and Margaret Thompson Mathewson, a physician, have spent many hours tracking down glass negatives, movies, and other materials pertaining to Finley and Herman T. Bohlman.

Below: Finley and Bohlman photograph a pintail duck in southeastern Oregon's Klamath Marsh in 1905. Right: Three years later they found this black-crowned night heron in Malheur Marsh, to the east.

THE WOMAN THAT NEVER EVOLVED

Sarah Blaffer Hrdy

What does it mean to be female? Sociobiologist and feminist Sarah Blaffer Hrdy shows us that evolutionary biology can provide surprising answers. She introduces us to our nearest female relatives – highly competitive, independent, sexually assertive female primates.

Hrdy proves that the sexually passive, non-competitive, all-nurturing woman of prevailing myth never could have evolved within the primate order.

"A spectacular and pioneering work!" — Jane B. Lancaster

"A stunning achievement." — Jessie Bernard, author of *The Female World*

Stellar Togetherness

Most stars in the Milky Way are members of binary or multiple systems, but no one knows exactly why

by Stephen P. Maran

Most astronomical facts are gleaned from new observations, but sometimes clever analysis of existing data discloses a significant pattern that had been overlooked. A good example is a 1974 investigation of binary stars by Virginia Trimble, an astrophysicist with the University of California at Irvine and the University of Maryland at College Park. Her study of data on what are known as spectroscopic binary stars led to a better understanding of how binary systems are formed.

A binary star, of course, consists of two stars in orbit around a mutual center of mass. A spectroscopic binary is a binary system that can be identified from the lines in its spectrum, whose wavelengths shift back and forth periodically owing to the Doppler effect as the two stars travel their orbits. Trimble analyzed the data on known spectroscopic binaries by estimating the "mass ratio" of each such binary star. This quantity is simply the mass of the "secondary," or fainter, star in the binary divided by the mass of the primary star. Thus, if the primary has twice the mass of the secondary, the mass ratio is 0.5, whereas if the two stars have equal mass, the mass ratio is 1.0.

Taking the ratio of two masses is a simple matter, but the results of Trimble's analysis were still very significant. She found that the distribution of mass ratios has two peaks: there are a large number of binaries with mass ratios close to 0.7 (meaning that the secondary star in each case has about 70 percent the mass of its primary) and there are also many binaries with mass ratios near 0.3 (the fainter star having just 30 percent the mass of the primary). By contrast, there are relatively few binaries with intermediate mass ratios, such as 0.5. The existence of two preferred values, 0.7 and 0.3, immediately suggested to Trimble that two different processes must be involved in forming binary stars. One process is apparently effective in making binaries with nearly equal masses (the 0.7 mass ratio systems), while the other process forms binaries with very unequal masses (the 0.3 mass ratio binaries).

Most stars are members of binary or multiple star systems. (Although the sun, which is single, is considered to be an average star, in this respect, it is *not* average.) The rarity of being single, which has long been suspected, was confirmed recently by several investigations carried out by Helmut A. Abt and Saul G. Levy, spectroscopists at Kitt Peak National Observatory in Tucson, Arizona.

To determine the relative occurrence of binary, triple, and quadruple star systems, Abt and Levy made thousands of spectrograms of hundreds of stars. Typically, they observed a star on twenty different nights and then compared the twenty spectra to see if their spectral lines shifted as a result of orbital motion. The results proved that single stars are indeed a minority. For example, in one 1976 study, Abt and Levy found that among stars resembling the sun (including those that are slightly hotter and brighter), 46 percent were observably binary, 9 percent were triples, and 2 percent were quadruple stars. A minority of 42 percent seemed to be single. (These numbers don't add up to 100 percent because they have been rounded off.)

Since 42 percent is not an extreme minority, one might think that the sun, as a single star, is not so unusual after all. Forty-two percent is actually an

¡Speak Spanish like a diplomat!

What sort of people need to learn a foreign language as quickly and effectively as possible? *Foreign service personnel,* that's who. Members of America's diplomatic corps are assigned to U.S. embassies abroad, where they must be able to converse fluently in every situation.

Now you can learn to speak Spanish just as these diplomatic personnel do—with the Foreign Service Institute's Programmatic Spanish Course

The U.S. Department of State has spent thousands of dollars developing this course. It's by far the most effective way to learn Spanish at your own convenience and at your own pace.

The Programmatic Spanish Course consists of a series of cassettes and accompanying textbook. Simply follow the spoken and written instructions, listening and repeating. By the end of the course, you'll be learning and speaking entirely in Spanish!

This course turns your cassette player into a "teaching machine." With its unique "programmatic" learning method, you set your own pace—testing yourself, correcting errors, reinforcing accurate responses.

This Programmatic Course comes in two volumes. Order one or both.

☐ **Volume I.**
12 cassettes, (17 hrs.), 464-page Text, and Instructor's manual, $115

☐ **Volume II.**
8 cassettes, (11½ hrs.), 614 page Text, and Instructor's manual, $98.

overestimate of the stars without companions, however, because some kinds of binary and multiple stars are hard to recognize as such (see "Searching for Dim Companions," *Natural History,* June 1981). So-called selection effects—that is, circumstances that may result in certain specimens being overlooked or underrepresented in a scientific survey—prevented Abt and Levy from identifying these difficult cases as binary or multiple stars. For example, binaries with very long orbital periods were missed because their orbital velocities are correspondingly slow and hence the Doppler shifts of their spectral lines are too small to measure. Also, if a secondary star is much less massive than its primary, the primary will orbit at very low speed while the secondary star orbits at high speed. Because the massive primary is much brighter, only its spectral lines will be detectable. The Doppler shifts of the massive primary star's spectral lines will be too small to measure and thus the binary will pass for a single star.

Still another selection effect occurs when the members of a pair orbit in a plane at nearly right angles to the line of sight from the earth. In that case, even though a pair may zip around their orbits at high speeds, there is no significant motion toward or away from the earth and thus no observable Doppler shift. Binaries of this type are also missed.

When Abt and Levy extrapolated the observed percentages of binary and multiple sunlike stars, increasing the percentages to compensate for those missed due to selection effects, the "42 percent single" category shrank dramatically. After making these corrections, Abt and Levy concluded that nearly all stars are at least binary, with a typical star having an average of 1.4 companions. (Thus, among every ten stars seen in the sky, there will be a total of about fourteen companions.)

Abt and Levy also made another important finding that brings us back to Trimble's discovery that two distinct processes are at work making binary stars. The Arizona team studied the masses of the secondary stars in binary systems and found that there are two types of secondaries that differ according to their orbital periods. Long-period binaries (those whose stars are widely separated from one another and whose large orbits take a century or more to complete) have secondaries that, as a class, are indistinguishable from the general population of stars in the Milky

Way. For example, among every 100 of these long-period secondaries, there are as many stars having 1 solar mass as there are among 100 stars chosen at random in the Milky Way, and there are as many stars of ½ solar mass as are found among 100 stars of the galaxy's general population. Stars with ¼ solar mass seem to be the most numerous of all in the Milky Way, and they are also the most numerous among the long-period secondaries.

But among short-period binary systems (in which the stars are fairly close together and take less than 100 years to complete their orbits), the secondaries do not have the same occurrence rates according to their masses as stars of the general Milky Way population. Instead of being most numerous at about ¼ solar mass, these secondaries tend to have masses approaching those of their primary stars. If we were to study 100 short-period primaries, each having 1 solar mass, for instance, we would find that ¼-solar-mass stars are not the most numerous among their secondaries. Instead, secondaries with closer to 1 solar mass would be the most numerous.

This distinction in the properties of mass between the secondary stars of long- and short-period binary systems was the second striking clue that two different processes form binary stars. From this second clue, we deduce that one process creates long-period binaries, in which the secondaries resemble the general population of stars. The other process, which creates the short-period binaries, somehow produces secondaries that are slightly smaller copies of their primaries.

The leading theories of binary star formation invoke the phenomena of fission, capture, fragmentation, disruption of clusters, and condensation of adjacent protostars, respectively. A star begins as a protostar, condensing from a cool nebula of gas and dust. As the protostar contracts and warms on its way to igniting nuclear reactions and becoming a real star, it spins ever faster. According to the fission theory, if the protostar spins fast enough, it will throw off matter, which then forms a companion protostar. The pair will eventually become true stars, constituting a binary system. Some astronomers believe that fission is inevitable and that it explains why almost all stars are binary or multiple. Nevertheless, there are objections to this theory. One is that tidal forces might prevent the ejected matter from condensing, just as tidal forces around Saturn seem to have prevented the particles in its rings from collecting into one or more moons. In addition, computations by Leon B. Lucy of Columbia University, an expert on binary stars, indicate that the matter ejected from a rotating protostar is sufficient only to form a secondary star with ⅛ the mass of the primary. Thus, the many close binaries whose primary and secondary stars have comparable masses could not form by fission. Finally, fission could not hurl the secondary star far enough from the primary to form a long-period binary.

According to the capture theory, a binary is created when two unrelated stars happen to pass close enough to each other to enable their gravitational attraction to form a permanent bond. This theory is more applicable to the long-period binaries with their large separations than to short-period binaries that are fairly close together, because stars passing randomly in space are more likely to pass at a large distance than at a small one (just as a badly thrown dart more often hits an outer target zone than the bull's-eye). The objection to this theory is that simple analysis shows that two passing stars will almost always keep on going; capture

The Soligor 80-200mm Expand Your Horizons By Getting Close.

You've got a terrific 35mm SLR camera, but not all of your shots are terrific. Some suffer from too much unwanted scenery, some from tiny people in big frames... shots that didn't work because your creative I.Q. was more than your *lens* could handle.

That's right, lens. But, Soligor has a solution: the affordable, innovative Soligor 80-200mm One-Touch Zoom + Macro lens that lets you and your camera turn blah into beauty.

Zoom in to crop out extraneous details. Bring your subjects up to 4 times closer than a standard lens can. Frame your shots exactly as you want them, and Soligor quality captures them faithfully. Create exciting portraits, instead of just pictures of people; capture a still life or sports action as the kind of picture you bought your camera to get; experiment with amazing close-ups, thanks to macro ability. And it's all so easy with Soligor's single One-Touch control for zoom, focus and macro.

If some of the zip has gone out of your picture taking, zip down to your Soligor dealer and try our 80-200mm on your Canon, Minolta, Pentax, Olympus, Nikon or other fine camera. Or, write for full information.

only occurs when an additional force (other than the gravity of the two stars) helps to slow the pair down. One suggested additional force is the gravity of a third star that may be nearby. But close approaches of one star to another are very rare and a three-way close approach would be extremely unlikely among unrelated stars. Two stars that already compose a binary system might be able to capture a third star and form a triple system, but at first glance, capture is an improbable way to form a binary to begin with.

In the fragmentation theory, a protostar does not condense toward the center, as is assumed in the fission theory. Instead, the protostar is supposedly shaped like a huge torus, or doughnut, and eventually breaks up into several fragments. Two of the fragments condense and form a binary star. Computer calculations by Lucy, which start out with the hypothesized torus, show that the protostar fragments can form a short-period binary. Further, in contradistinction to the fission theory, fragmentation does seem capable of making binaries with nearly equal masses. We are not certain, however, that protostars will form toruses rather than condensing toward their centers.

The theory that binary stars form by cluster disruption assumes that the members of a small star cluster escape, leaving just two stars, which then constitute a binary. There is more to it, but that is the general idea. This theory begs the question of how the cluster itself formed. Further, if virtually all stars are at least binary, as determined by Abt and Levy, then how do the escaped stars get their companions?

Finally, the theory that binary systems are created by the condensation of adjacent protostars is the least profound of all. It postulates that from a single nebula two protostars condense close enough to each other to enable gravity to make them a binary star. This theory is applicable to widely separated, long-period binary stars: protostars are so much larger than the stars they eventually become that if two protostars were close enough to form a close binary, they might merge into a single protostar or tidally disrupt each other.

What if two protostars formed at distant locations within a large nebula and then happened to pass each other? One star might capture the other since the nebula would be a retarding medium, and the retardation could constititute the additional force that (as explained above) is necessary for the capture process. This variant of the capture theory could account for the formation of long-period binaries with their unrelated secondary and primary star masses.

The work of Trimble, Abt, and Levy tells us that two processes are at work, forming two different kinds of binary stars. We are not sure how that happens, but another process—the process of elimination—suggests that, among current theories, fragmentation can best account for the short-period, close binaries with their members' comparable masses. Either capture in a nebular environment or condensation of adjacent protostars may explain the long-period binaries with their unrelated masses.

In some binary systems, mass flows from one star to its partner in the form of a gas stream or of a stellar wind. This further complicates astronomers' efforts to interpret the mass ratios. Explaining exactly how a single star is born is hard enough, but binary stars are clearly double trouble.

Whales at Table

Text and photographs by James W. Greenough

Banqueting in the cold waters off Alaska, humpback whales lunge at their prey with mouths agape

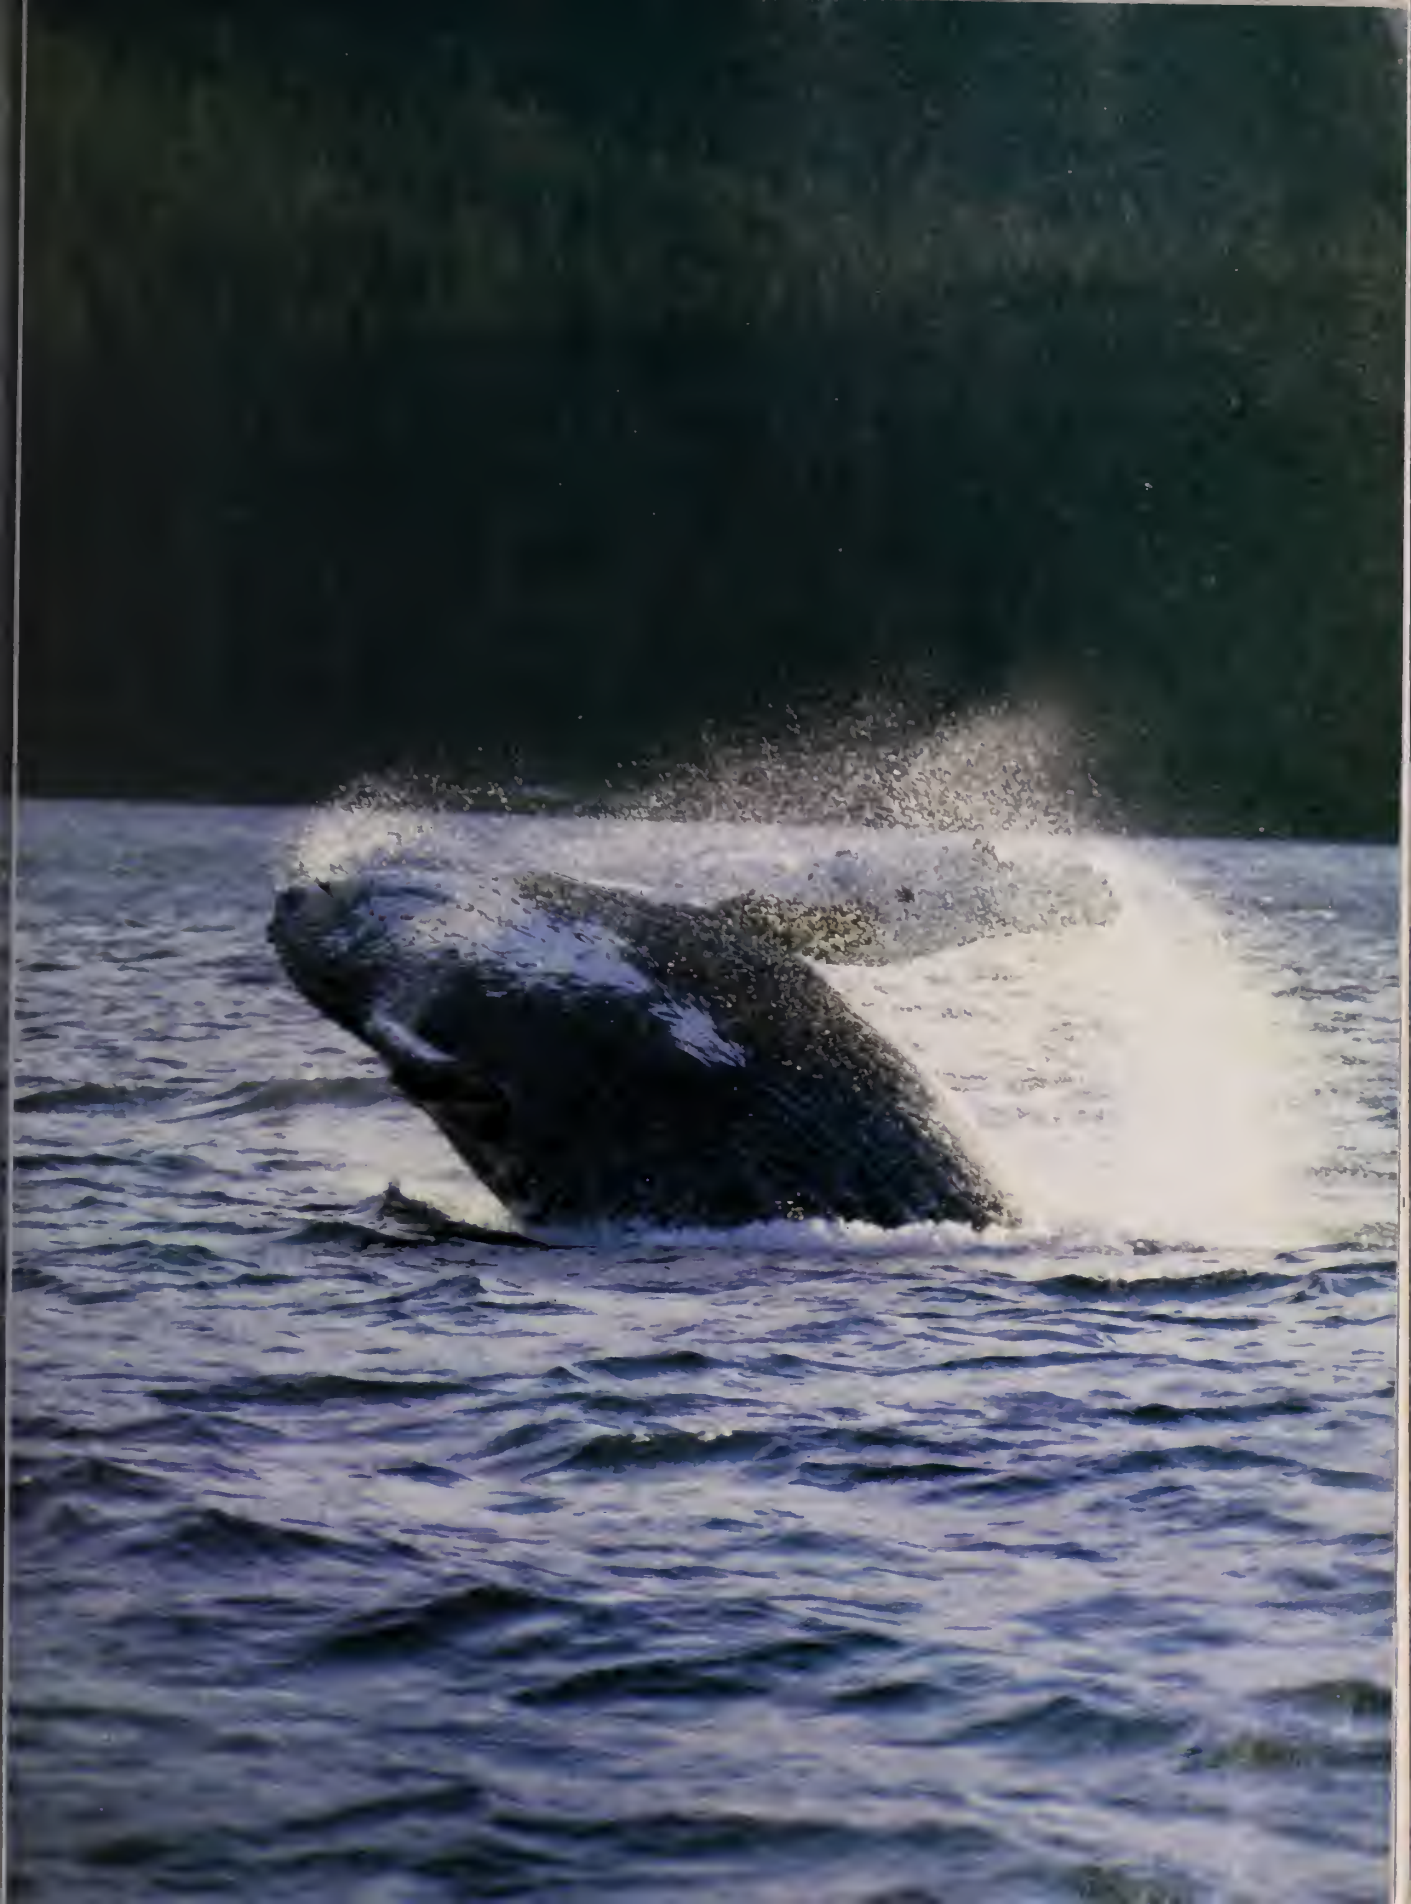
Although not a biologist by education, I am a scientist of sorts—and an inveterate observer of wildlife. I am especially excited by great whales, even though I see them routinely while running my commercial fishing boat. So when the opportunity arose to spend some time watching a group of humpback whales in southeast Alaska during late November and December 1980, I didn't turn it down. One late fall morning I transported John and Jan Straley of Sitka, Alaska, two whale observer friends, to their chosen bay off Admiralty Island.

Well known among whale watchers as the most acrobatic of the great whales, the humpback leaps into the air more than any other species. Nearly everyone interested in whales has heard of or seen the dramatic breaches of the humpback, in which thirty or forty tons of bulbous flesh erupt from the sea. Yet the humpback's most dramatic behavior may well be its eating habits. The huge humpbacks (regularly about forty feet in length and occasionally over fifty feet) feed on a variety of tiny to small organisms, the largest of which is usually the herring (sometimes up to ten or twelve inches, more commonly six inches). Needless to say, it takes a great many herring to feed one humpback whale. Specialized techniques are required to round up and capture such quantities of fish. The techniques that humpbacks have evolved are both spectacular and complex.

For three weeks we watched a group of twelve to fourteen whales surface feed continually during daylight hours. We were intrigued because it is not common knowledge that some humpbacks remain in Alaskan waters and continue to feed so late in the season. With the coming of cold weather and short daylight hours, the humpbacks generally head for warm tropical waters where they mate and rest, but do not feed. Indeed, most humpbacks had departed Alaskan waters by November, but for some reason these errant whales were still actively feeding in early December.

Humpbacks sometimes feed well below the surface in moderately deep waters, but the type of feeding we watched, known as "vertical lunge" feeding, was done at the surface. The process, as performed by one whale, is simple. The whale sounds (dives), locates a school of herring (or a dense concentration of tiny organisms such as krill and plankton), then lunges upward through the prey, mouth agape. In this way it fills its gullet with herring and seawater. The gullet becomes greatly distended, expanding along the longitudinal pleats in the whale's ventral surface. The whale's mouth closes tightly, and then, with its huge tongue, it forces seawater out through its mesh of baleen while retaining the herring.

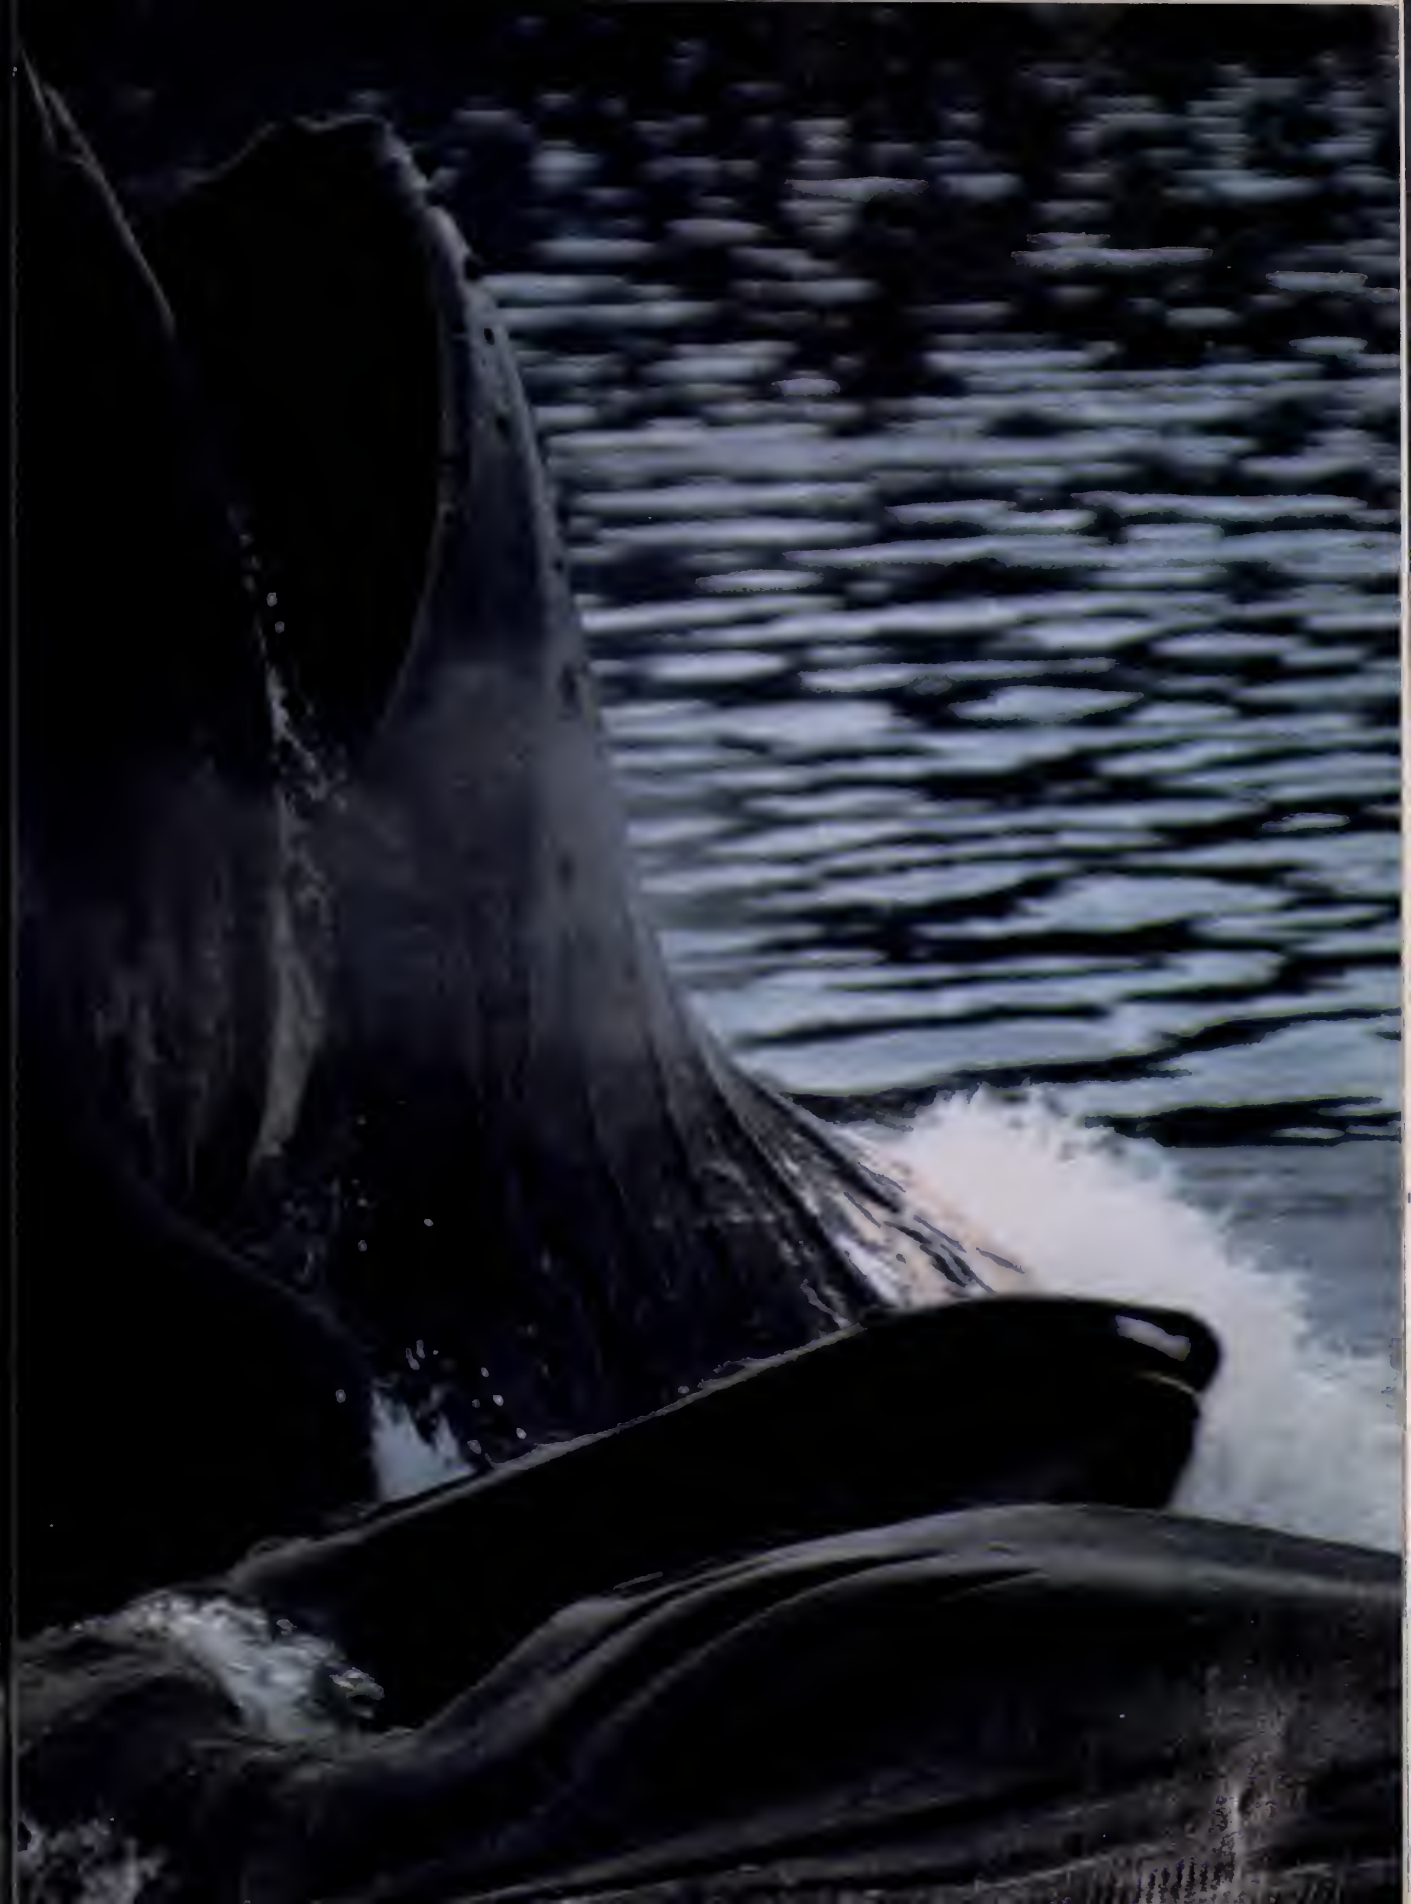
A variation is the "horizontal lunge," in which the whale pursues its food across the surface of the water. Horizontal lunges are made with the whale in virtually any orientation. At times the whale is on its side, often with one flipper out of the water, the lateral surfaces of both upper and lower jaw exposed. At other times its dorsal surface and upper jaw are exposed in a posture reminiscent of a crocodile on the rampage. Or the whale may be completely overturned, its pleated ventral surface and cavernous lower jaw protruding from the sea. Between the vertical and horizontal lunges there is a full range of possible angles in relationship to the sea's surface.



Lunge feeding in a single whale is dramatic enough, but when six or seven of these huge mammals lunge in a coordinated effort, the effect is stunning. Such group feeding seems more common than lunge feeding by individual whales, and we rarely saw fewer than three participate in a lunge. The maximum number we observed was seven.

When such a group of whales feed together, it is not a loose association. Often the whales seem to be actually touching each other, so tightly are they grouped. The entire variety of lunge patterns was regularly observed in a single group lunge. Lateral, ventral, and dorsal surfaces of horizontally lunging whales, interspersed by one or two whales clearing the surface in vertical lunges, were a common sight. To see seven whales (weighing a total of perhaps 250 tons) erupt within a fifty- or seventy-foot circle, their lunges timed within a second or two, is awesome. Even more to the point, it suggests a respectable ability to communicate and coordinate actions.

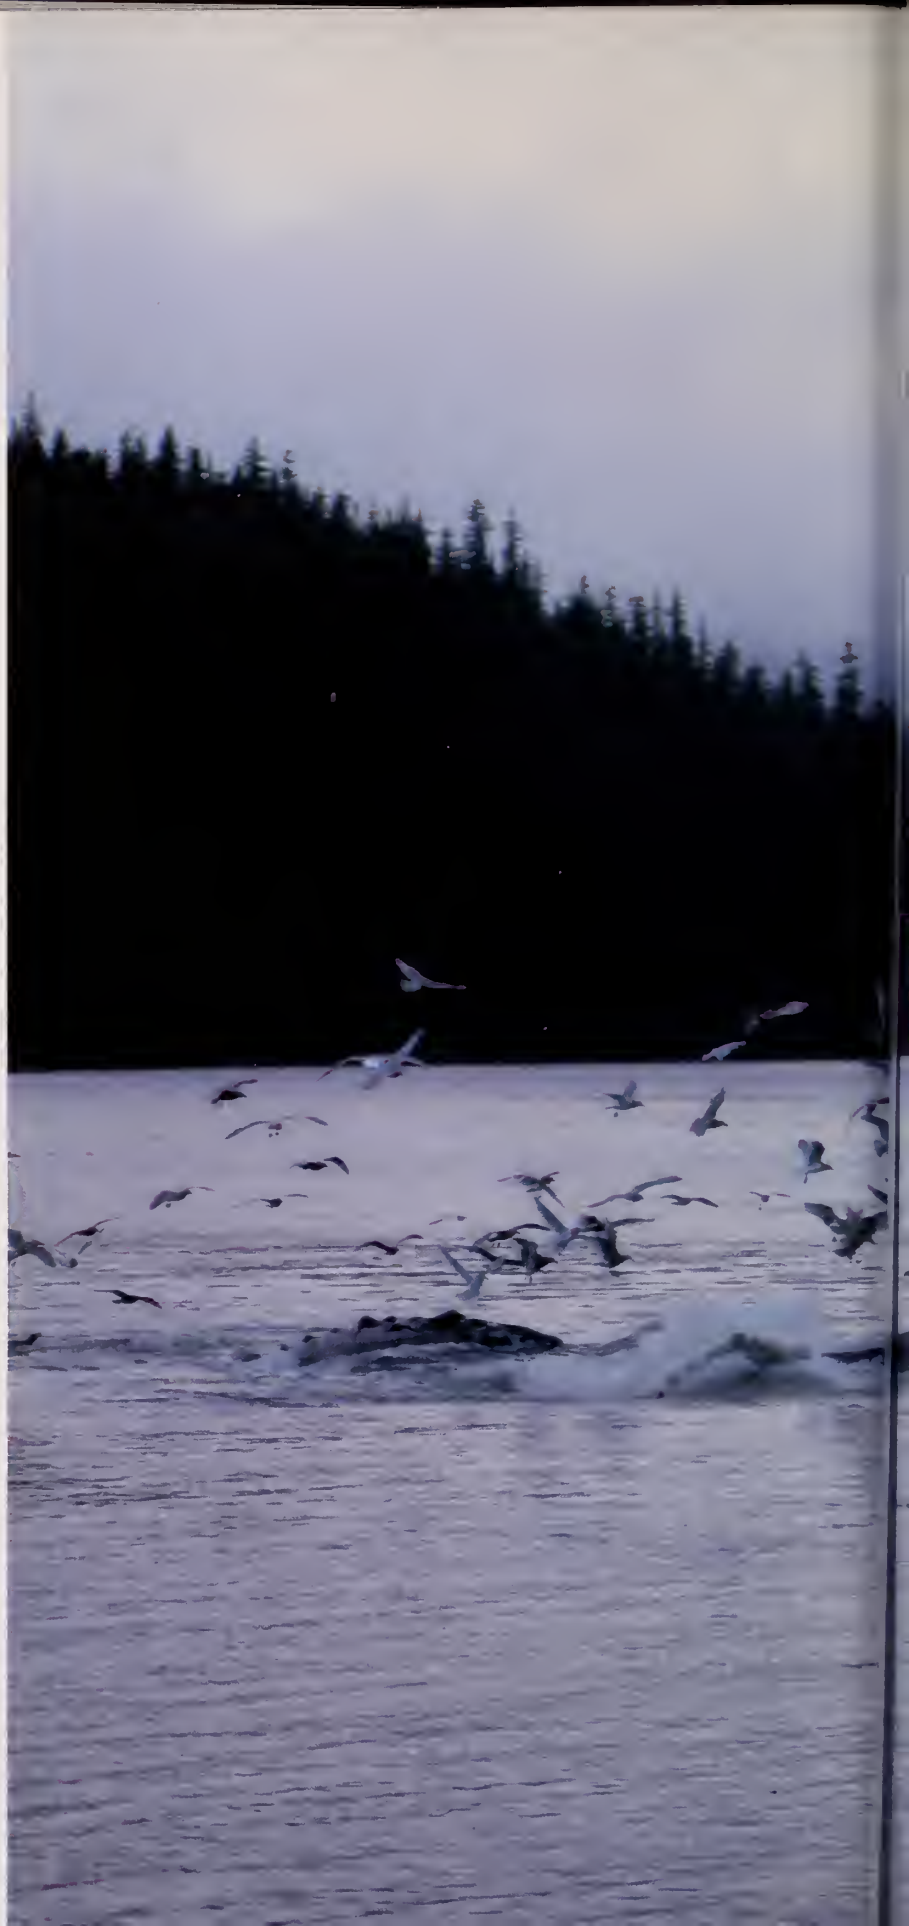
Almost as fascinating are the ways humpbacks prepare for feeding. Or, to be more objective, how they increase concentrations of the prey before expending energy lunging. Bubble-net feeding is the most sophisticated method humpbacks employ to optimize food concentrations. One or two whales swim upward from below the prey in a closing spiral, blowing a constant stream of bubbles. The bubbles rise faster than the whales and form an ever narrower net around the trapped fish. The herring, following their instinct to flee from anything flashing in the water, swim away from the bubbles and gather at the center of the bubble-net. The whales then lunge upward, filling their gullets with seawater and herring. It has been reported that whales may vary the size of the bubbles in the net to suit the type of prey—small bubbles for tiny fish and large ones for larger fish such as herring. Bubble-net feeding has also been reported with plankton and other passively drifting prey.



No visible behavior of the whales can match the bubble-net for subtlety. On

A humpback whale breaches the water off Admiralty Island, Alaska.

Groups of four to six humpbacks commonly lunge-feed together, showing exquisite timing and coordination. In one instance, seven whales erupted from the water within a seventy-foot circle, their lunges coming no more than two seconds apart.



the other hand, when the whales elect to use brawn rather than brain, some interesting things happen. Breaching, lob tailing, and other surface behaviors are occasionally used as herding methods. A whale engaged in lob tailing raises its flukes and a portion of the rear end of its body clear of the water, then forcefully slaps the flukes down on the surface. This is sometimes done with a direct up and down motion of the flukes. At other times, it involves a tremendous diagonal sweep with the flukes and resembles nothing so much as a whale turning cartwheels. In either case, lob tailing results in a tremendous splash and, if you happen to be a herring swimming in the vicinity, a stunning concussion. Thus lob tailing may serve both to stun nearby herring, allowing leisurely feeding, and possibly to drive or herd herring.

Both lob tailing and breaching are performed at times by individual whales, and on some occasions certainly serve purposes unrelated to feeding. We saw instances of a humpback lob tailing on the fringes of a group of whales engaged in feeding. It may have been that the lob tailing (or breaching) whale was coordinating its efforts with those of the other whales, assisting by pushing food toward the pod. Such whales are helping to set the table if you will permit such an image. Once the table is set, the humpbacks are noisy and enthusiastic eaters; one constantly catches glimpses of herring streaming down chins.

Our observations of humpbacks feeding in Alaska during the late fall and winter months raise more questions than they answer. Which whales are wintering-over in the north? Are they sexually immature whales? Or old whales? Or are they cows with calves? And why do they stay? Do they need more food? Can't they make the long journey south with their peers? And is it the same group that stays each year or a different one?

By spending large portions of their own winters watching the humpbacks in remote and rainy regions of Alaska, whale researchers are looking for answers to these questions. □

When a group of humpbacks feed on fish, vertical and horizontal lunges can be seen simultaneously. Seagulls circle overhead, for dead and injured fish offer easy pickings for these scavengers.

Seduction on the Wing

Male thynnine wasps have been known to carry off a female, copulate with her in flight, then drop her

by John Alcock

Among insects, parental behavior is fairly widespread and sometimes highly sophisticated. But the active parent is almost always the mother. An explanation of why, in general, male insects provide their mates only with their sperm can be gleaned from evolutionary theory. Evolution occurs when individuals differ in how many of their genes they are able to pass on to the next generation. If there is variation in the behavior of males in a species, with some males offering assistance to their mates and others providing sperm only, logic dictates that the number of genes contributed by the two types will determine which behavior spreads through a population over time and which will disappear. There is good reason to believe that, under most conditions, males that provide their mates with nothing more than sperm and attempt to copulate as frequently as possible will outreproduce those that allocate some of their limited time and energy to help one or more of their female partners.

To understand why this is the case, consider that males produce smaller gametes than females: sperm are much smaller than eggs. A male usually is able to manufacture so many sperm that he could theoretically fertilize a large proportion of the eggs produced by all accessible females. The male that copulates with a large number of females will have great genetic influence on the next generation, and so the potential evolutionary pay-off of a "Casanova strategy" is extremely large. In contrast, a male that invests in mate-helping behavior must divert energies that could go toward finding and copulating with additional females. The helpful male limits his opportunities to pass on his genes to the progeny of the relatively few females he can assist.

Yet there are male insects that do provide useful services or materials to their partners, as in the case of male giant waterbugs that carry the eggs of their mates on their backs until the young hatch. In other species, males provide food that is used to feed their offspring. Among the dung beetles there

While copulating, a male thynnine wasp (left) gathers nectar from a flowering eucalyptus. The wingless female will soon receive a nuptial gift of the nectar. By feeding his mate, the male may help to insure that it is his sperm that will fertilize her eggs.

A.G. Wells

A.G. Wells

Right: This female has emerged from her burrow in the ground, climbed a piece of vegetation, and is calling for a male by releasing into the air a sex pheromone unique to her species. Far right: Diverse methods of feeding females are used by the male wasps. In this species, the male regurgitates a drop of nectar on a leaf and the female, in copulo, *twists her body underneath the male to imbibe the food.*

are species in which a male may help his partner dig a burrow nest and provision the brood cells with choice dung balls on which the female lays her eggs. In still other insects, males collect food that their mates consume. For example, in certain empidid flies and the unrelated hanging flies, the male captures an insect prey, kills it, and then offers the food to a female as a nuptial gift that she consumes during copulation.

This type of behavior poses an evolutionary puzzle: Why are these males able to transmit more of their genes than would potential competitors using all their time and energy to reach a larger number of receptive females? Randy Thornhill of the University of New Mexico has provided a plausible explanation for the genetic success of helpful male hanging flies. He has found that females that do not receive a nuptial present simply refuse to copulate. Moreover, if the male offers a gift that is not sufficiently large, the female will terminate the copulation prematurely and seek out another male. Once the female has fed to satiation on a large nuptial gift and copulated with the male that presented it, however, she becomes unreceptive for a time to further matings with other males. During that interval, she lays a series of eggs fertilized by her recent mate's sperm. The male's gift to the female therefore advances his own genetic success.

A similar explanation may apply to the evolution of the male mating behavior displayed by some thynnine wasps of Australia. There are well over 500 species of these wasps in Australia, many of them undescribed and most of them unstudied. Judging from the results of the few behavioral studies conducted thus far, however, some features of their biology may be widespread among the group. To begin, the females of these supposedly primitive wasps are wingless, a trait that is related to their method of molelike burrowing through moist soil in woodlands and meadows in search of beetle larvae. When a tunneling female encounters an appropriate victim, she stings and paralyzes the larva, lays an egg on the prey, and excavates a small chamber around it. The egg she leaves behind hatches into a grub that consumes the beetle larva and eventually metamorphoses into an adult wasp.

In a number of species, after a newly adult female emerges from her pupal case she burrows to the surface and crawls up a grass stem or weed. When she has reached a point well above the ground, she adopts the calling posture standard for her species. In many cases this involves perching head-up, with the head held out from the stem. But in other species, the female turns to face down the stem or twig. And in still others, the female holds her abdomen stiffly out at an angle from the perch. In all species studied to date, the female releases a sex pheromone while in the calling position.

Male thynnine wasps possess wings, and often their major activity is to fly about in areas in which females are calling. In my studies of several species in eastern Australia, I captured and then marked males with dots of paint on the back of the thorax. After releasing the marked wasps, I later attempted to net patrolling males in the same area. Individuals were regularly caught as much as two weeks after they had been marked, indicating that the males had home ranges in which they searched day after day for mates.

When a male detects the pheromone of a female, he zigzags upwind toward her. (Although females of several species may release pheromones in the same area, they only attract males of their own kind, presumably because each species produces a unique sex pheromone.) When a male reaches the grass blade or plant stem on which the female is perching, he frantically half-scrambles, half-flies through the foliage in an effort to reach the female before his competitors can find her. The male that makes first contact almost always wins the female, quickly picking her up and carrying her off *in copulo* in a nuptial flight. In some thynnine species, the male transports the female some distance from the call-

John Alcock

ing perch (and away from other males that will fight for possession of a mate) to the relative tranquillity of a nearby resting spot where copulation commences.

Mating patterns of this sort are common among insects, with females calling males to them and accepting the first male of their species to reach them. But what occurs in the thynnine wasps is unique among the Hymenoptera (the wasps, bees, and ants) and unusual among insects generally. Male thynnine wasps often provide their mates with food, offering nuptial gifts analogous to the prey presents given by male hanging flies to females. Unlike hanging flies, these wasps are not predatory but instead feed on the nectar of flowers or the sugary excreta of plant-feeding bugs. Hence their nuptial feeding behavior is somewhat different from that of the hanging flies.

In some thynnine species males merely transport their mates to a source of food; while the male walks forward drinking nectar, the female, linked in copulation, trails behind, also feeding. But in other species, the male's role in feeding his mate is more pronounced. A common pattern is for the male to carry the female, which usually assumes a coiled position at the tip of the male's abdomen (the better to be carried in flight), to a source of nectar. There, the female remains coiled in a ball, head tucked under the male's abdomen, while the male moves energetically from flower to flower or sugar droplet to sugar droplet, collecting liquid food and storing it in his crop. At intervals of several minutes, the male stops foraging and in some way signals to the female; she extends her body and he regurgitates a droplet of fluid to offer to her.

Just as species differ in the coiled carrying position adopted by the female, there are also consistent species-specific patterns of food exchange among thynnines. In some, the male holds the droplet of food in his mouth and the female stretches forward and consumes it. In others, the male deposits a droplet of food on a leaf or branch and the female uncoils, drinks the fluid from the leaf, and then resumes the carrying position. The male laps up any liquid left behind.

There are thynnines in which the male does not offer the female many small regurgitated meals, but instead feeds himself extensively prior to searching for a mate and then offers the female a single large meal during copu-

John Alcock

Right: Males of this species, while copulating, fly from flower to flower collecting nectar. Every few minutes, the female in a mating pair will twist around and drink directly from the male's mouthparts. Far right: These thynnine wasps spend the night in pairs on the plants from which they gather nectar. In the morning the males resume feeding their attached mates. The females' coiled carrying position is typical of their species.

lation. In a species found in southern Australia, the male, after achieving copulation, excretes from the tip of his abdomen a large drop of viscous fluid that the female imbibes while coiled in a U position beneath his abdomen.

All thynnine males expend considerable effort, either before acquiring a mate or during copulation, to secure food for the female. Collecting nectar consumes time and energy that cannot be allocated to the search for additional mates and thus reduces the number of females a male can find in his lifetime. How is male reproductive success advanced by the expenditure of effort to gather nuptial gifts? Because females are wingless, they are probably unable to collect food as efficiently as a male. By providing a nuptial gift for a female, a male saves her the expense of gathering nectar, enabling her to spend more time and energy searching for a beetle larva on which to lay her egg. Moreover, the helpful male provides his mate with nutrients that may contribute directly or indirectly to egg development. Therefore, if the gift-giving male's sperm are used to fertilize the female's egg, he is investing in the propagation of his genes when he feeds her.

Indications are that females that have been adequately fed will not mate again for some time. After nuptial feeding, the pair flies to a spot likely to contain larval prey. As they circle low over the ground, the female disengages from the male and falls to the earth. She remains immobile for a minute or two and then springs to life, scuttling across the ground for a short distance before burrowing into the soil, often at the base of a weed or grass clump. Australian entomologist T.J. Ridsdill Smith found in his study of *Hemithynnus hyalinatus* that females remain underground for about a week, reemerging to call again for another male, another meal, and another copulation. Presumably, if the female had succeeded in finding a beetle larva during her week in the earth, the larva would carry an egg fertilized by the sperm of her most recent partner. Perhaps if females do not receive sufficient nutrients to sustain them for some time underground, they will resume calling at once when released by a male, attract another partner, and receive sperm from him that might supplant those donated by the inferior gift giver. (Geoffrey Parker of the University of Liverpool has found that in insects whose females engage in multiple matings, the last male to copulate before egg laying usually has a reproductive advantage.)

I performed many simple experiments in which I captured and separated mating pairs of several species that had not completed their period of nuptial feeding. Although this must have been a somewhat traumatic experience for the wasps—rough handling was often necessary to get them to disengage—in most cases the female resumed calling almost at once, sometimes even before she had been removed from the insect net in which the pair had been captured. It was not unusual to have several males buzzing frantically about the net a minute or two after a copulating pair had been separated. These experiments indicate that females do have the potential to mate more than once in a short period. Hence a gift-giving male does gain an advantage by feeding his mate adequately, thereby encouraging her to go underground to search for beetle larvae after mating with him rather than remaining above ground and soliciting another mating and more food.

Thus females that are able to mate multiply and displace old sperm with each copulation can actually make it advantageous for a male to provide a food gift for them. When nuptial presents originate, the trait will spread because the sperm of males that do not feed mates will tend to be superseded by the sperm of gift-giving males. Male wasps provide the present because it is in their own genetic interests to do so, but in one sense they have been manipulated by the mating behavior of females. If egg fertilization becomes contingent upon receipt of an acceptable meal, only males that offer food will receive a genetic return from copulating.

Given the advantages to female hanging flies and thynnine wasps in receiving assistance from their mates, one wonders why other female insects have not evolved traits that make helpful actions the adaptive option for males. Perhaps they have. For a growing number of species, ranging from houseflies to butterflies, it is now known that males transfer materials along with the sperm during copulation and that the quantity of these substances determines how long the female waits before she copulates again and receives a competitor's sperm. In some cases it has been established that the extra materials are metabolized by the female and used to produce her eggs. Thus males of many insects may be forced to offer nuptial presents in one form or another if they are to fertilize the eggs of their mates. □

Protean Beauty

An artist's sampling captures the varied beauty in a diverse family of plants

Illustrations and text by Willard K. Martin

Proteus, prophetic old man of the sea in Greek mythology, had the power to change his shape at will, an ability he used to avoid capture by those trying to make him divulge his knowledge. Among plants, the family Proteaceae is an aptly named group of diverse plants whose often showy inflorescences and seed capsules come in a rich variety of forms and colors.

The flamboyance of many Proteaceae flower clusters is due largely to long, colorful bracts, modified leaflike structures. Members of this family typically grow in parts of the world that have a long dry season every year, and their bracts and other leaves tend to be covered with hairlike outgrowths and protected by a thick cuticle that reduces the water lost in transpiration.

Proteaceae characteristically bear clusters of individually small flowers, which may be pollinated by insects, birds, mice, or small marsupials. Some of these are strikingly large clusters. South Africa's king protea (*Protea cynaroides*), a member of one of the family's largest genera, may reach nearly a foot in diameter, and the erect flower cone of Australia's yellow bull banksia (*Banksia grandis*) can include as many as one thousand tiny flowers in a spike up to a foot and a half tall. Other species of various sizes and shapes resemble pincushions, thistles, or asters.

The genus *Banksia*, or Australian

Banksia baxteri

As the many small flowers of the Banksia baxteri *inflorescence drop off, they leave behind a woody seed cone. The cone contains many ovaries, but only a few develop seed capsules. These capsules mature into beautifully colored protuberances covered with delicate white and golden hairs.*

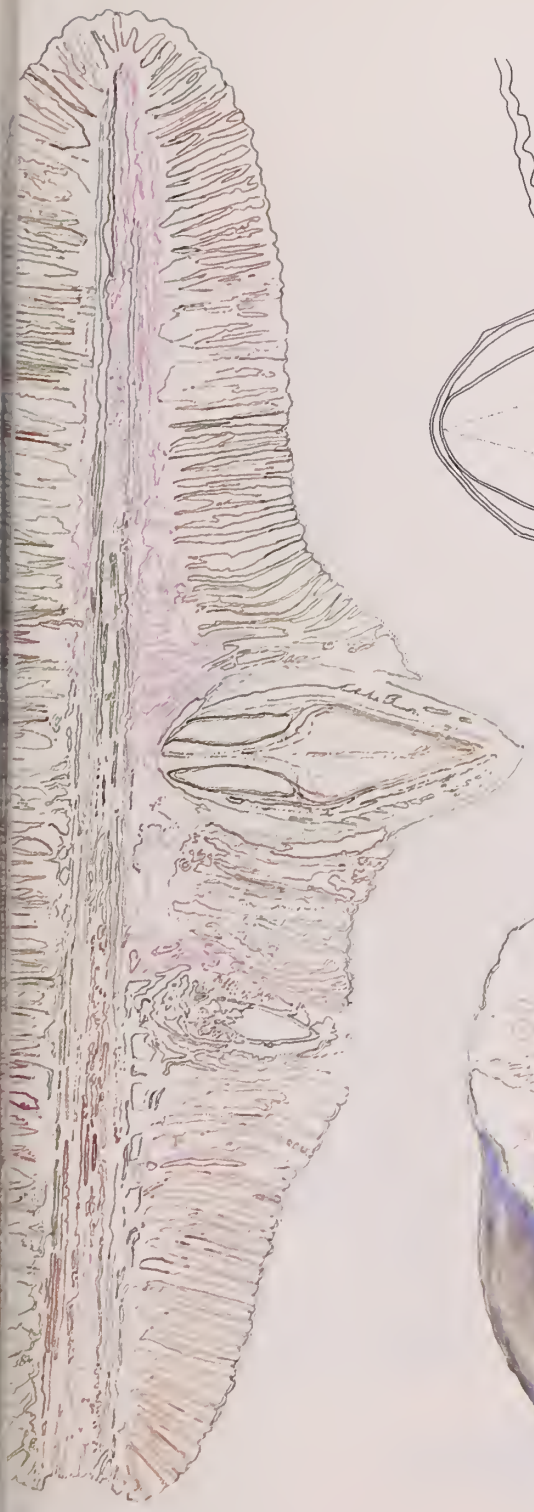
Winged seed

ripe seed cone

honeysuckles, was named after the British naturalist, explorer, and patron of science Sir Joseph Banks, who accompanied Capt. James Cook on his 1768–71 expedition to Australia. In 1770, when Cook discovered the inlet just south of present-day Sydney, he named it Stingray Harbour. Later, the harbor was renamed Botany Bay in recognition of the many plants Banks found in the area. In addition to the Australian honeysuckles, he discovered giant figs, palms, tree ferns, the flame tree (*Brachychiton acerifolium*), and the crimson-flowered waratah (*Telopea speciossima*).

Banksias are among the most diverse members of the family, ranging from prostrate shrubs, with inflorescenses that seem to lie on the ground, to trees that grow up to fifty feet high. Pollinated primarily by honey eaters, all Australian honeysuckles produce copious nectar, and many are valuable sources of honey. Australian aborigines make a honey drink by soaking the dense flower spikes in water, and in many areas of the countryside, children often collect the nectar by banging the flower heads against a dish.

In suitable habitats, within the plants' natural range and outside it, Proteaceae are frequently cultivated in public and private gardens. In Hawaii, outstanding specimens of these plants are grown at the agricultural experimental stations on the islands of Maui and Oahu. The macadamia nut tree (*Macadamia ternifolia*), a Proteaceae native to Australia, is an important commercial crop in Hawaii. Many varieties of Proteaceae are now grown commercially in California, mostly from seeds and rooted cuttings imported from New Zealand and South Africa. The colorfulness of the bracts enhances their appeal and their stiffness lengthens the life of cut flower heads; dried, the heads and bracts are often sold as centerpieces for arrangements.



Dead or alive, wild or cultivated, these beautiful and variously shaped members of the family Proteaceae will captivate all who see them as surely as the family's namesake tried to avoid capture.

Developing seed capsules expand greatly on the seed cone of Banksia menziesii. *At maturity, the capsule, or nodule, pops open, releasing two winged seeds.*

How the Rabbit works: The Diesel.

Oil is a natural liquid energy-storage system. It is produced by burying undecomposed organic matter under hundreds of tons of pressure for 200 million years. Prudence dictates that we use it sparingly.

Which is the fundamental advantage of Dr. Rudolph Diesel's compression ignition engine. Speed and power are controlled directly by restricting the fuel supply.

The engine can have all the air it wants, but only enough fuel to accomplish the job at hand. At idle, that can be as low as 4 tablespoons an hour. Although very efficient, it is also very slow and heavy, unfortunately placing it at odds with the concept of the small passenger car.

Nothing else is a Volkswagen.

To address these disadvantages, VW introduced the lightest 4-cylinder Diesel ever produced. A wider power band and substantially improved performance were provided by a new swirl-chamber, aluminum cylinder head. Fuel economy remained phenomenal.

There are several Diesels on the market, and if all you want is to be prudent, they all should be of passing interest. If you're interested in passing too, there is only one choice.

The Rabbit Diesel. Also known as the best mileage car in America.*

*EPA estimated 45 mpg 58 highway estimate. (Use "Estimated mpg" for comparisons. Your mileage may vary with weather, speed, and trip length. Actual highway mileage will probably be less.)

Survival in Space

Extreme cold is only one of the hazards for astronauts who venture outside a spacecraft

by Bruce Webbon

Unprotected in the vacuum of space, a human being would survive for only a few minutes before swelling up (because water vaporized inside the skin would not be able to escape as fast as it vaporizes) and becoming freeze-dried. Accordingly, without artificial life-support and protective systems that emulate the earth's environment, manned space flight would not be possible.

Humans evolved in an atmosphere composed primarily of oxygen and nitrogen at a pressure of approximately fifteen pounds per square inch. Although it may often seem very hot or very cold, the earth's atmosphere provides a relatively benign temperature environment within an average range of about ± 100 degrees Fahrenheit. It seldom gets colder on Earth than −80° or hotter than 130°. By contrast, space lacks a true atmosphere and the temperature range may go from −460°, an approximation of absolute zero, to 300° or higher.

The main requirements for survival in space are oxygen at an appropriate pressure, supplies of food and water, and systems to control the humidity, insure a comfortable temperature range, remove carbon dioxide and other gases, such as sulfur dioxide, and handle our solid and liquid wastes. Designing equipment to satisfy these requirements within the smallest spaceship of all—the spacesuit—is especially difficult.

The fundamental purpose of the spacesuit is to establish around the astronaut's body an artificial atmosphere containing oxygen. To maintain life and to saturate the blood with oxygen, the oxygen pressure in that atmosphere must be greater than approximately 2.5 pounds per square inch but there is no need to have a maximum pressure higher than our normal one. The spacesuit must also protect the astronaut from other hazards, such as bombardment by micrometeoroids. Because the intensity of sunlight is much greater above the shield of the earth's atmosphere, the side of the suit facing the sun may get very hot, while the other side, exposed to deep space, may get very cold. The suit must therefore be insulated to protect the astronaut from these temperature extremes. The earth's atmosphere also guards us from some of the high-energy radiation in space; the spacesuit must accordingly provide some degree of radiation protection.

Today's spacesuits evolved from the high-altitude flight suits designed in the 1930s and 1940s to protect airplane pilots and balloonists. Those suits, in turn, were originally derived from deep-sea diving suits. The first experimental high-altitude suits were developed in the early 1930s by Mark Ridge, an American aerial stunt man, in conjunction with the British physiologist J.B.S. Haldane. Known for his research on the physiological effects of deep-sea diving, Haldane worked with Ridge to develop a suit that would protect high-altitude balloon pilots. In 1933 Ridge tested the suit in an altitude chamber at a simulated altitude of 90,000 feet—approximately a mid-stratospheric height. At 90,000 feet the air is very thin, so this suit is considered to be the world's first spacesuit. But Ridge's dream of using it to fly in a high-altitude balloon never materialized, and the suit was never used again.

Wiley Post, a well-known test pilot and aviation daredevil, also dreamed of setting a high-altitude record in his Lockheed monoplane, the *Winnie Mae*. Post worked with engineers from the B.F. Goodrich Company to develop the suit that he used for a series of high-altitude flights in 1934 and 1935. But Post never got the opportunity of using his suit to set an official high-altitude record; on a flight with the American humorist Will Rogers, in August 1935, the plane crashed, killing them both.

Data provided by these early, pioneer-

Astronaut Edwin E. ("Buzz") Aldrin, Jr., dressed for a walk on the moon. The photograph was taken during the Apollo II *mission in 1969 by Neil A. Armstrong, the first person to step on the moon.*

NASA

ing modifications of deep-sea divers' suits were used by World War II designers to develop suits that would protect the crewmen flying at high altitudes in unpressurized planes. Above about 30,000 feet, a protective suit is necessary. The development of pressurized suits for use in high-altitude military aircraft continued throughout the 1950s. With the elimination of pressure points (places where the suits rub against the body), the suits became more comfortable and mobile enough to permit the operation of aircraft controls.

In 1958 the newly formed National Aeronautics and Space Administration (NASA) initiated Project Mercury, whose goal was to put manned space capsules into orbit around the earth. To attain this objective, suits and life-support systems had to be developed that could be used for many hours at altitudes of more than 100 miles.

The requirements for the Mercury spacesuit were similar to those for high-altitude military aircraft. The suit served as a backup to the space capsule's pressurization system. It had to be comfortable when worn unpressurized for hours on end, but it did not have to provide much mobility because the Mercury astronauts remained seated in the capsule at all times. Since the suit was not meant to be used outside the capsule, it did not have to protect the astronauts from temperature extremes and the other hazards of space.

The Project Mercury spacesuit was, in fact, two suits—one inside of, and attached to, another. The inner suit was made of rubber, and its purpose was to contain the gas—pure oxygen in this case—used to pressurize the suit, exactly as gas is contained within a balloon. Rubber, however, is highly elastic and, like a balloon, the inner suit expanded if it wasn't restrained. That was the function of the outer suit, which was made of a heavy, synthetic canvaslike fabric and resembled a workman's coveralls.

The astronaut entered the spacesuit through a zippered opening. A helmet and gloves were then mechanically attached. A hose connected to the capsule's life-support system supplied the astronaut with oxygen for breathing, and a second hose removed his expired carbon dioxide from the suit. The carbon dioxide was extracted and the purified gas was then recirculated. Any protective suit will interfere to some degree with the mobility of the wearer. But the astronauts of Project Mercury and the early Gemini missions—our second manned space project—did not leave their capsules. Their suits were designed for use exclusively within a severely limited area and therefore did not need to be very flexible.

NASA

Space suit, above, was designed in the early 1930s for American aviation daredevil Wiley Post. Contemporary prototype units, right, are the result of half a century of evolution.

The first American to venture outside a space capsule was astronaut Edward White during the flight of *Gemini IV* in June, 1965. This first so-called extravehicular activity, or EVA, was simply an experiment to demonstrate that astronauts can survive in space when given the proper protective equipment. White was connected to the Gemini capsule by an "umbilical cord" that supplied oxygen and communication lines. Problems that arose during White's and succeeding Gemini EVAs indicated that more sophisticated suits and life-support systems would be needed if astronauts were to perform useful work in space.

When these early-model suits were pressurized, moving about in them required a great deal of physical effort. This not only tired the astronauts but also caused them to become overheated. There are two main reasons why extraordinary effort was required to move around in those suits. First was friction created between moving parts. Every time an elbow or knee was flexed, the rubberized inner suit rubbed against the

Anthony Wolff

outer restraining fabric suit. Second, just like an inflated balloon, a pressurized spacesuit is forced by the pressure of the gas within it into an inflated and stiffened position. When an astronaut moves in a suit in that condition, the gas inside the suit is slightly compressed, but the energy to compress the gas is supplied by the astronaut.

A spacesuit easier to move around in and a portable life-support system that would allow the astronauts to be independent of their space capsules were clearly needed for the Apollo moon landing program of the late 1960s. The purpose of the Apollo mission was to explore the lunar surface, set up and perform a variety of scientific experiments, make geologic observations, and collect lunar samples. The Apollo spacesuits had to shield the astronauts from the hazards of the lunar environment and provide the necessary life-support systems for periods of up to eight hours during which the astronauts would be walking on the moon.

Most people have seen pictures of white-suited astronauts on the lunar surface. Very few people, however, have ever seen an actual Apollo spacesuit. The familiar white suit is only an insulated outside cover made of canvaslike material, worn over multiple layers of thin plastic film coated with an aluminum spray. The surface of the moon can get as hot as 250°to 300°F where it is exposed to the sun. The shaded areas, on the other hand, can get as cold as −250°. Because the moon has almost no atmosphere to filter out incoming solar radiation, the astronaut is also baked by direct rays from the sun. The white outer suit was designed to insulate and protect the astronaut from these extreme temperatures, but unfortunately, at the same time, it seals in the heat produced by the astronaut's body.

Nylon mesh garment worn under modern spacesuits is equipped with soft plastic tubes that carry cooling water. Below, a model already wearing the lower section of a suit crouches to get into the upper section.

Anthony Wolff

All living creatures generate heat as a result of the metabolic processes that maintain life. A resting human adult produces about as much heat as a 100-watt light bulb. When working hard, the same individual can easily generate ten times as much heat energy. The human body has built-in temperature regulation systems that maintain safe body temperatures of about 97° to 102° during normal activities on the earth. Skin temperature is controlled by blood flow to the skin and sweat rate. Body heat is carried away primarily by the circulation of the air around us and by the evaporation of sweat. But an astronaut enclosed in a pressure suit and an insulated protective suit must be cooled by other means.

Relatively little attention was given to cooling during the Mercury and Gemini programs. The Gemini suit incorporated a system of ventilation ducts that was intended to cool the astronauts by blowing oxygen from the capsule over their bodies. Experience showed that this system was inadequate to cool someone who was working hard while wearing a pressure suit. Therefore a liquid-water cooling system was developed for the Apollo program. The Apollo astronauts wore a liquid cooling garment (LCG) under their spacesuits and next to their skin. The LCG looks like a suit of long underwear with a network of fine, flexible tubing attached to it. Body heat was removed by cool water pumped through the tubes. In addition, the Apollo suits had urine containment and transfer systems, and the astronauts wore a diaper-like garment under the LCG, just in case. These cooling and elimination processes were found effective and they are still in use in the suits designed for the space shuttle.

A backpack first introduced in the Apollo program was a key protective element. All of the life-support systems carried by the astronaut were in this

backpack. Oxygen for breathing on EVAs was in a pressurized tank in the pack. The oxygen was metered into the suit by a regulator that also controlled the suit pressure. The oxygen was circulated by a small fan driven by an electric motor. Gas leaving the suit contained the carbon dioxide exhaled by the astronaut, as well as evaporated sweat and trace gases, such as sulfur dioxide and hydrogen sulfide, produced by the astronaut. The trace gases were absorbed in the backpack by a filter bed made of activated charcoal. The sweat was condensed by a device, called a cooling heat exchanger, that cooled and dehumidified the gas before it was recirculated back into the suit. The carbon dioxide was removed by a chemical, lithium hydroxide. The gaseous carbon dioxide reacted with the hydroxide to form a salt, lithium carbonate. This reaction removed the carbon dioxide as fast as it was produced and the suit gas, enriched by oxygen from the storage tank, was sent back into the helmet through a duct.

The LCG water that had been warmed by the astronaut's body heat was pumped into a cooling device in the backpack called a sublimator. Water from a separate storage tank in the pack was also fed into the sublimator, where it was evaporated by exposing it to the vacuum of space. This evaporation process removed heat from the LCG water so that the cooled water could be recirculated. The water vapor from the sublimator was simply vented overboard. On the earth, this Apollo backpack weighs about 130 pounds, but on the moon it weighs only about one-sixth as much.

The Apollo program demonstrated that space-suited astronauts can work routinely outside their spacecraft. The Skylab program, which followed in the early 1970s, demonstrated the usefulness of EVAs. Skylab's EVAs were quite different from the tasks of lunar surface exploration done during Apollo. The primary reason for the Skylab's EVAs, planned prior to the launch of that spacecraft, was to periodically change film canisters in cameras mounted outside the cabin as part of earth resources and astronomy experiments. The astronauts worked near the capsule airlock so that a life-support system could be maintained through an "umbilical" hose and an autonomous backpack was not necessary. The Skylab spacesuit assembly was essentially the same as that of the Apollo system.

During the unmanned launch of the Skylab laboratory, one of the solar panels was damaged and failed to deploy in orbit. Part of the cabin's exterior insulation was also damaged so that the cabin became very hot. If these problems had not been solved, the entire Skylab program would probably have been canceled. The only solution was to have suited astronauts launched in another spacecraft manually perform the repairs outside the Skylab craft. The problems were compounded because those repairs required the astronauts to work 100 miles up in space on capsule areas where no handrails or tether attachment points had been installed. Handrails are needed for safe movement between the airlock and the work site, where a tether could be attached to hold the astronaut in position while working. The first Skylab crew nevertheless successfully made the needed repairs.

During the period between the end of the Skylab program in the early 1970s and the first shuttle flight in 1981, a new spacesuit was developed. For one thing, women were admitted into the space program as astronauts beginning in 1977. To no one's surprise, they needed smaller suits than those worn by the male astronauts. From the initial Mercury program through the Skylab program, all the spacesuits had been custom tailored to fit individual astronauts. But beginning with the space shuttle in 1981, the suits have been made in separate units of different but standard sizes and were assembled for the astronauts more or less "off the rack." The new spacesuit when assembled is similar to the Skylab suit, except for the torso, which is now made of fiberglass instead of rubber and fabric. The life-support systems in the backpack are permanently attached to the hard fiberglass torso, rather than being removable, as in Apollo. This change improved the reliability of the systems and simplified the hours-long checkout procedures required before an EVA. The shuttle suit operates with an internal gas pressure of approximately one-fourth of an atmosphere—the same pressure as that of earlier suits. The life-support system is functionally identical to that of the Apollo system, although considerable redesigning was required to integrate the systems with the hard torso.

The shuttle spacesuit and life-support system will be used for the first few years of the shuttle program to allow the astronauts to perform a wide range of EVA tasks. Many satellites, such as the large space telescope, are being designed for maintenance and repair by suited crewmen. This is simpler and cheaper than trying to accomplish the same job with a robot. Nevertheless, automated systems are needed for other jobs, such as maneuvering large payloads in the shuttle's cargo bay, and for assembling large space structures.

The current space shuttle EVA system has many shortcomings that preclude its use for routine space construction operations. About two pounds of

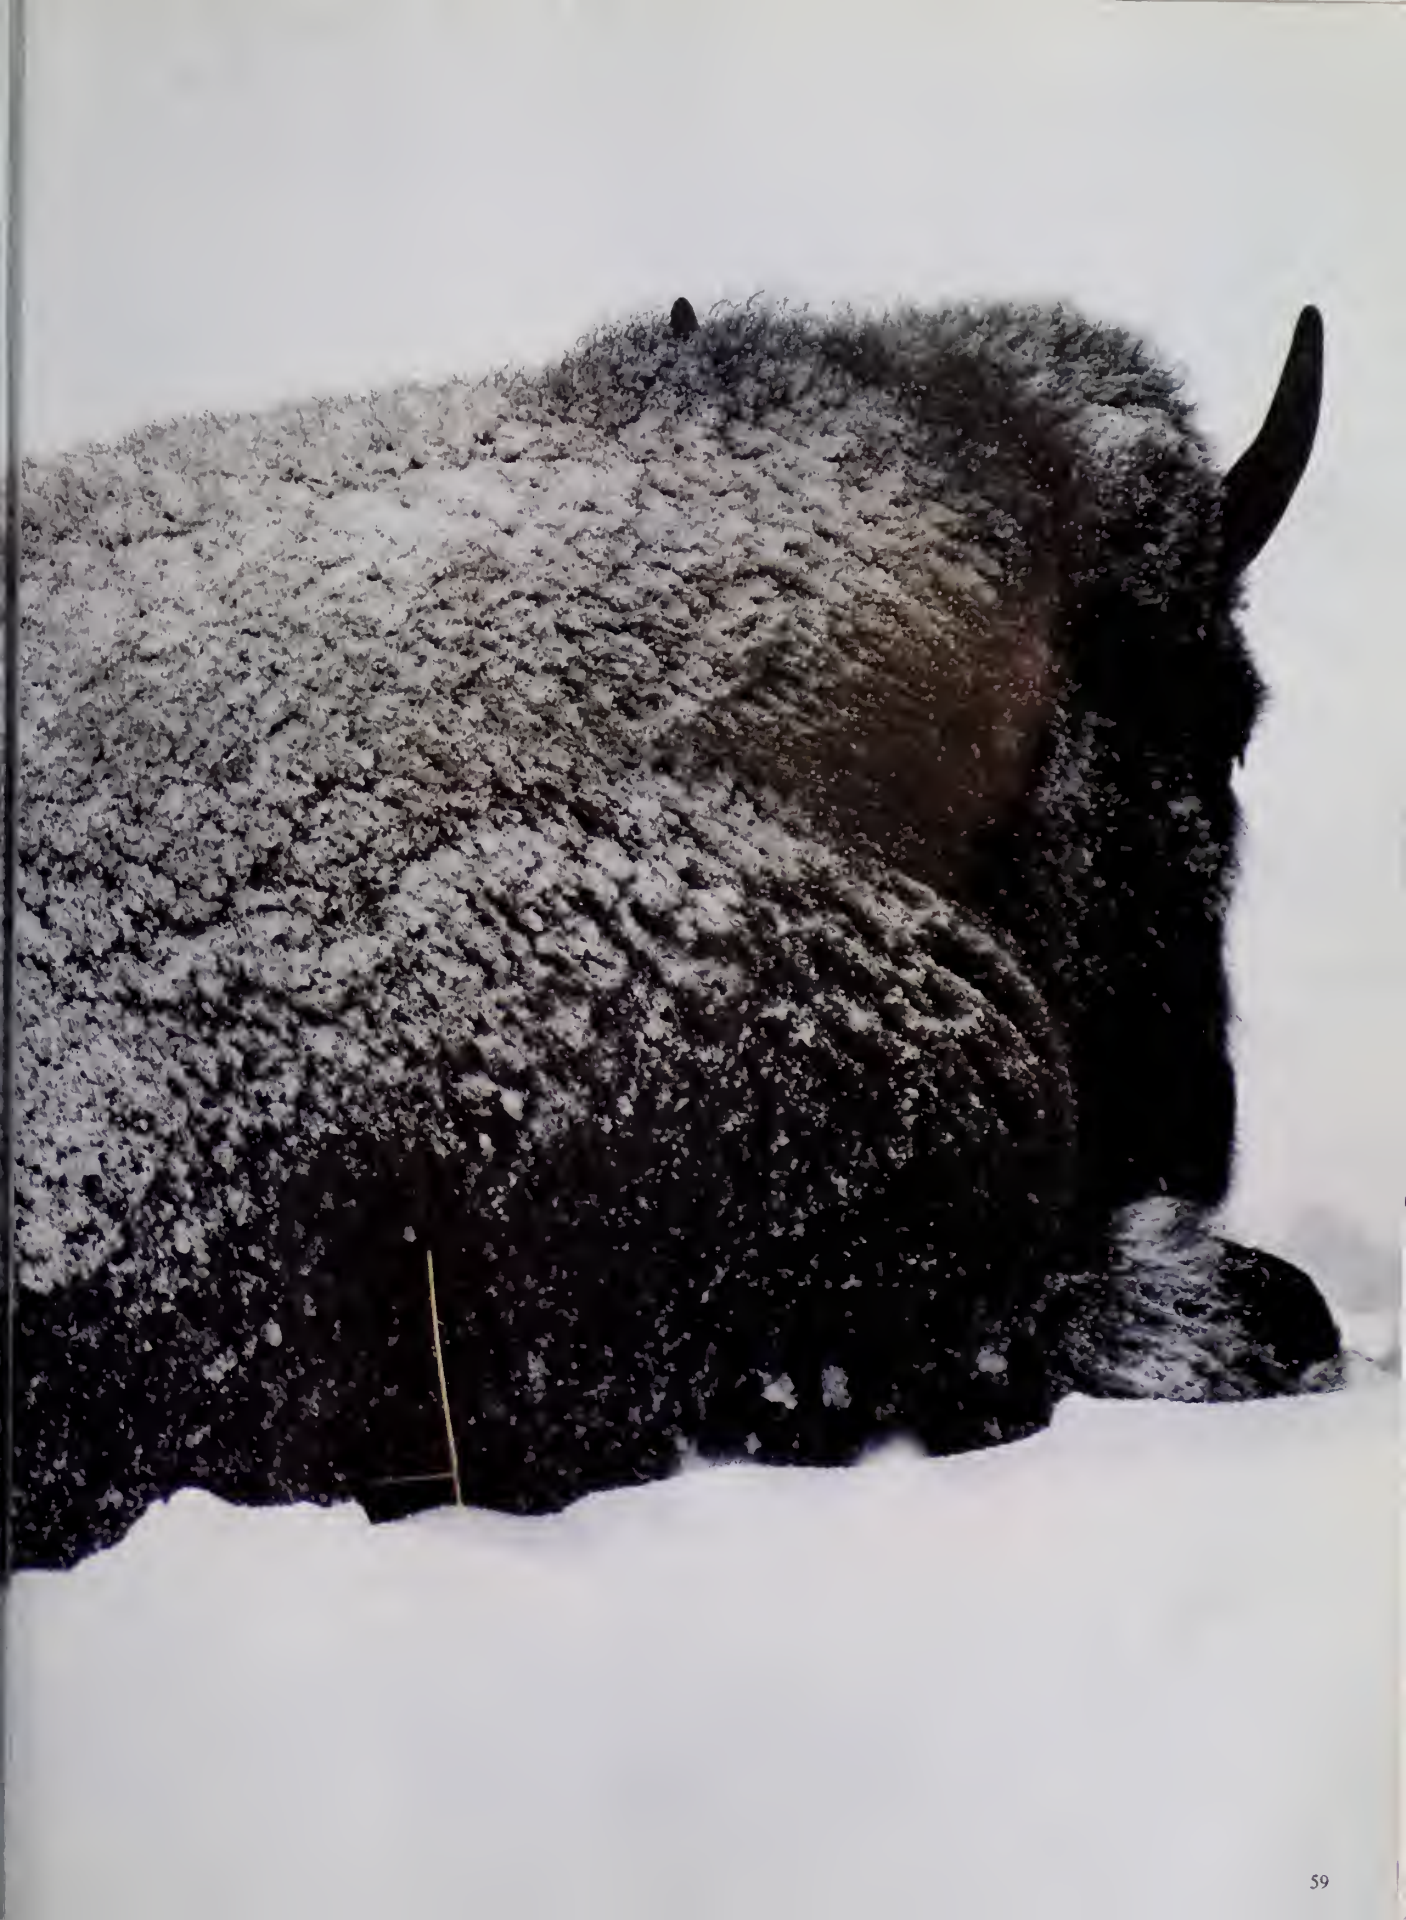
Early mission suits, shown here, were custom tailored for individual astronauts. Today's suits come in standard small, medium, and large size units that are then assembled to give a "custom" fit.

John Grossman

cooling water and lithium hydroxide are used up by the shuttle backpack during each hour of operation in space. Since these expended materials must be resupplied from the earth, many thousands of pounds would be required to support large construction crews working in space. To resupply the cooling water and lithium hydroxide required for expendable systems is too expensive; therefore, cooling and carbon dioxide control systems that can be regenerated for reuse must be developed.

The spacesuit for this "blue collar" EVA system must be durable and reliable enough for months of daily use with only routine maintenance. It must also operate with an internal pressure higher than one-fourth of an atmosphere—on the order of one-half of an atmosphere or more. This is needed to avoid the potential danger of decompression sickness, or "the bends," when the astronauts decompress from the pressure of one atmosphere in the shuttle or space station cabin to the lower suit pressure. This is exactly the same bends problem that deep-sea divers may encounter when ascending after a dive. In both cases, the problem occurs when the ambient pressure around the body is reduced after a period in which the body's tissues and fluids have become saturated with nitrogen and the body is in equilibrium with its surroundings. The pressure reduction takes place at the end of an extended deep dive and requires decompression stops on the way to the surface. It occurs at the beginning of an EVA. The bends are avoided when using the shuttle suit by having the astronaut breathe pure oxygen for three hours prior to an EVA. This period of wasted time would be intolerable for routine EVA operations.

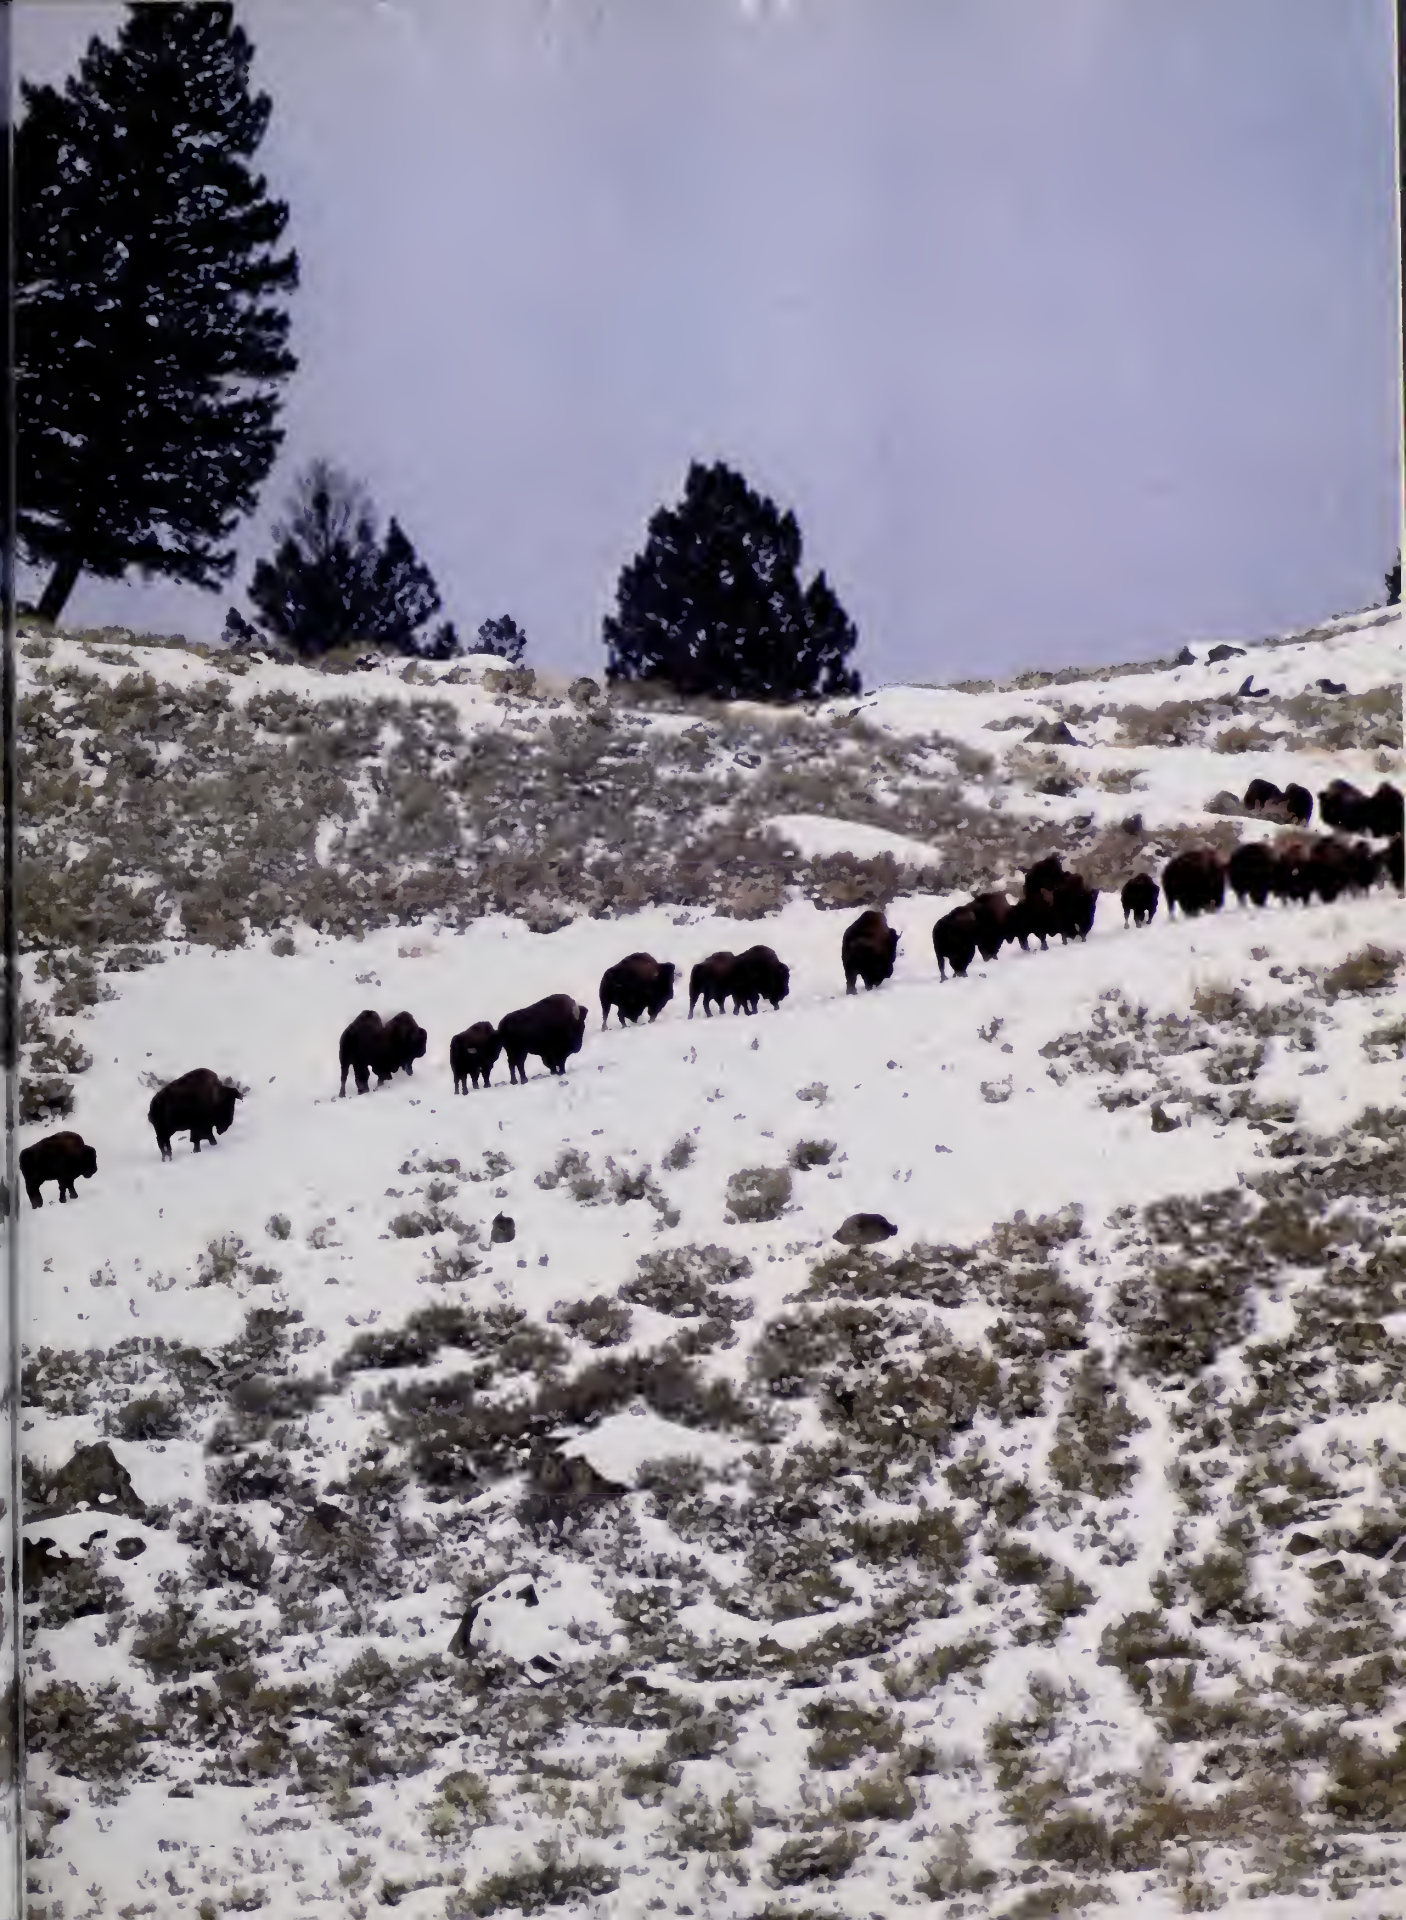
As already mentioned, the suit, which now comes in separate pieces, can be assembled according to the requirements of a particular mission. The basic torso with integral, regenerative life-support systems could have lightweight fabric arms and legs attached when it is to be used in low Earth orbit and arms and legs with additional shielding as protection from radiation when used at higher altitudes. This shielding could easily be provided by making the suit extremities and the torso out of the same material, probably a metal such as aluminum.



Many future space missions have been suggested. Before they become reality, however, new portable life-support systems must be developed. □

Yellowstone Buffalo Winter

Photographs by Jeff Foott



Snow. In Yellowstone National Park, the accumulated flakes of winter precipitation exert a strong influence on the movements of the buffalo herds. Mixed herds, bull groups, and solitary bulls are increasingly confined to wintering valleys as the snow deepens. The animals can scrape away the snow to depths of at least three feet to get at the forage beneath. Relatively secure in the valleys, they pass the winter rummaging through the snow, obtaining enough food to carry them over to spring.

There are winters, however, when some buffalo don't survive. Normally, buffalo can plow through heavy snow, doing so when they move to another valley after having exhausted the forage in one area. Mixed herds can be seen traveling in line, plunging trenches in the snow. But the snow sometimes proves impassable. When this happens, buffalo mortality rises as the food supply of the trapped animals runs out. The severe winter of 1964–65 saw snows that blocked a group of buffalo in a slough in the Bechler Meadows. Eighteen of the animals starved to death.

Llama Caravans of the Andes

For centuries, llama trade caravans have provided the principal link between pastoralists of the Andean highlands and agriculturists who inhabit the valleys

by Terry L. West

From Lake Titicaca in Bolivia, the Desaguadero River meanders southward for 200 miles to Lake Poopó. Off the southern edge of this lake, at an altitude of some 12,000 feet, lies the canton of Pampa Aullagas. The 3,000 Aymara-speaking inhabitants of this cold and arid plateau region subsist on a combination of pastoralism and agriculture, raising sheep and llamas for meat and wool and cultivating potatoes and quinoa, a native cereal. Because frost and drought endanger even these high-altitude crops, which are the dietary staples of the area, the people of Pampa Aullagas depend on exchange with people living at lower altitudes, where agriculture is less precarious. Like pastoralists throughout the Andean highlands, they not only have the motive to engage in trade but also possess the means—

On a ten-day journey from the Peruvian highlands, a llama caravan carries potatoes to Arequipa to be traded for lowland produce.

animals that can transport the products that come from the various levels of this "vertical environment." Llamas, in addition to serving as a source of animal products and as local beasts of burden, have for centuries been assembled into caravans for this long-distance trade. More sure-footed on the rugged terrain than the burros (and horses) imported by the Spaniards, the native llamas are also cheaper to maintain. They can forage along the route for their food, while burros, the usual beasts of burden in nonpastoral areas, require fodder that has to be grown or purchased.

As accustomed as they may be to physical discomfort, the Aymara find journeying with llamas an extraordinary hardship. "To travel with llamas is to suffer," is the refrain of those familiar with the experience. In recent years, as the people of Pampa Aullagas have found alternative means of obtaining valley products, they have tended to abandon the arduous task of conducting llama caravans. Many drovers have so depleted their stock of male llamas by butchering them for market that they lack sufficient numbers to outfit future expeditions. When llama caravans were the rule rather than the exception, however, they helped occupy the dead time between the May harvest and the September planting. In years of poor harvest and famine, entire families embarked on such caravans in the search for food.

Because of a severe drought, the harvest of 1977 was a dismal one, giving me the opportunity to take part in a llama caravan that under other circumstances would probably not have been organized. The instigator was fifty-year-old Sergio, who was accompanied by his new son-in-law, Hilario, age twenty-seven. Hilario confided to me that at that time of the year he normally would be in the Department of Santa Cruz working as a migrant laborer, but he was going along out of obligation to his new father-in-law. The rather domineering Sergio had also succeeded in getting Hilario to convince his own father to join them. Four years older than Sergio,

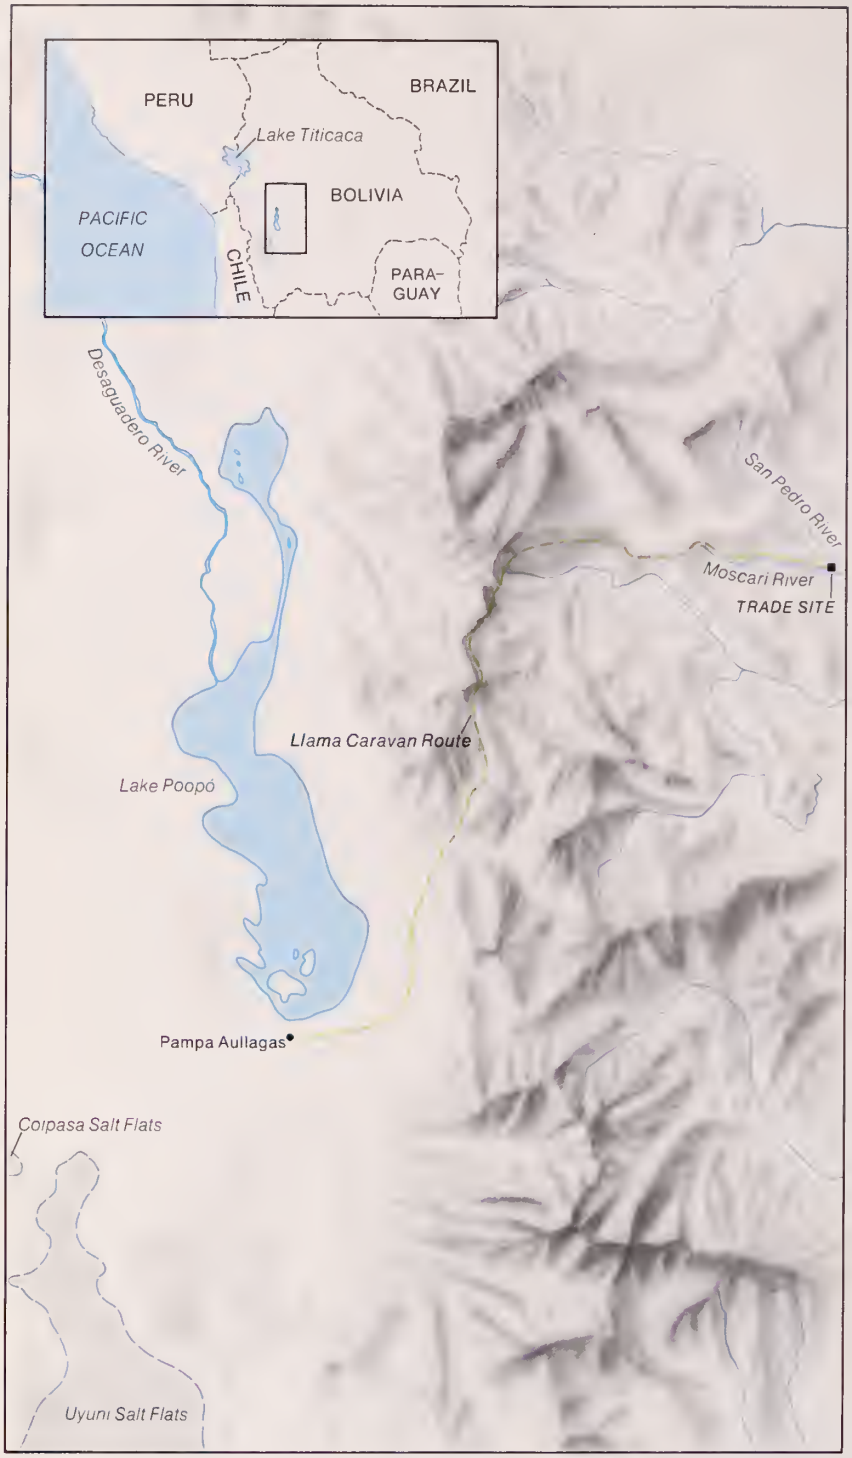
Llamas are useful as beasts of burden on both long- and short-distance trips. Above: Llamas near Lake Titicaca transport goods to market. Right: Individual ownership is indicated by the notches in a llama's ears.

Gregorio had last gone on a caravan in 1974. Because of his age he had not anticipated going on any more, and he had gradually sold off the thirty mature pack llamas he had used on his last caravan, butchering them for the meat market.

Before we began to load for our departure, which took place May 17, there was a brief farewell ceremony. Sergio's aged mother provided a tin incense holder, and Hilario's older brother and wife supplied alcohol. Everyone present sat or squatted in a semicircle, exchanged coca leaves for ritual chewing, and drank sugar cane alcohol. By turns, the three drovers bared their heads and knelt in prayer. Holding the burning incense tray aloft, each beseeched the earth spirits for a safe and successful trip. Then we loaded our cargoes and set out on our journey.



Llama caravans from Pampa Aullagas may be termed salt caravans because salt is the bulk of the cargo the Aymara inhabitants take to trade. In the past, drovers made a one-week trek with their llamas to the salt flats of Uyuni, sixty miles to the south. There they purchased salt from the local residents, pausing a week before making the return trip. Now, most acquire the salt from truckers who transport it to Pampa Aullagas for sale. Then, following the harvest, troops of cargo-laden llamas and their drovers depart Pampa Aullagas on a three-month trade circuit to valleys in the east, where the salt is exchanged for the products of the local Quechua-speaking agriculturists. These include wood, medicinal herbs, and above all, foodstuffs, among which maize ranks first, both for domestic and ceremonial consumption. Until the last few years, no major ritual ceremony in Pampa Aullagas was complete without the serving of corn dishes and maize beer, and even now, guests who enter the houses of local authorities on special occasions are expected to genuflect before a wall altar containing ears of corn. Drovers on caravans will kiss the first few ears of maize they receive en route in exchange for a handful of salt. They also recite prayers to the *tunari*, or "valley," where maize is grown.

On the basis of precedent, drovers from Pampa Aullagas visit specific valley destinations so that both men and cargo are dispersed equitably throughout trade areas. This enables drovers to estimate the quantity of salt they need to take and the amount of maize they will receive. It also assures long-term relations with specific *caseros*, or "trade partners." Since the Aymara drovers and their Quechua clients share neither ethnic, kinship, nor communal ties, the establishment of binding *casero* agreements represents the main link between two otherwise distrustful populations. The potential theft of cargo or animals worries drovers, whereas valley residents are concerned about crop damage from strayed llamas. If drovers have been known to cheat on measurements, valley people have been known to receive cargoes on trust and disappear without reciprocating. Establishment of *casero* ties—and concomitant personal ones—mitigates this mutual distrust. To further cement their bond, *caseros* exchange gifts and services and, in some cases, sanctify their ties through the

Andrew Tomko

Despite the growth of commercialism and motor transport, traditional llama caravans are still to be found in Andean South America. While in Bolivia in 1977, the author accompanied one such caravan from Pampa Aullagas (elevation more than 12,000 feet) into the eastern chain of the Andes and down to a valley trading site. The llama drovers took salt obtained from the Uyuni salt flats near Pampa Aullagas to trade for corn and other valley products that cannot be grown in the high-altitude environment.

institution of *compadrazgo*, the relationship of co-parenthood that is established between parents and godparents.

Drovers learn routes and acquire *caseros* by accompanying their fathers, uncles, older brothers, or other men as helpers. As one drover explained, "When one serves as a helper, you are introduced to people. The next year, when you return to the area, you have your clients. When you travel with your father, you make *caseros* with the sons of his *caseros*."

Most of the veteran drovers that I met began their apprenticeship as helpers to their fathers at age six to eight. A helper is usually a man's son or nephew but can be a daughter or niece if a male helper is not available. Also, young men whose own fathers lack llamas may volunteer to assist drovers to whom they are unrelated. In this way, they obtain maize for their parents, plus experience for their own eventual caravans. The standard compensation for such helpers in Pampa Aullagas in the 1970s was the free use of five of the employer's llamas for the transport of the helper's own trade goods.

Helpers are expected to perform irksome, low-prestige chores, such as fetching water and gathering dung for fuel. On our 1977 expedition, Hilario served as helper mainly to his father, while I acted as Sergio's helper. The caravan contained a total of fifty-five llamas, of which twenty-eight belonged to Gregorio and his family and twenty-seven to Sergio. There were also three burros to carry utensils and provisions and to serve as pack animals once we reached our destination. Each drover was responsible for looking after his own animals and conducting his own trading, although on the march the animals intermingled freely, with one man walking behind them and one on each side of the caravan.

Only male llamas are used as pack animals, and they are usually castrated because the drovers believe that this makes them more resistant to fatigue. Caravan llamas range in age from three to seven, with ages four to six regarded as the best. Whenever possible, caravan veterans are selected as lead animals. The average mature male llama can carry a load of about seventy-five pounds, with some capable of sustaining a hundred pounds over short distances. To avoid unduly fatiguing their llamas, most drovers limit their cargo weight to between fifty and sixty pounds.

The salt we transported came in both solid blocks and granulated chunks. The

NOW WE KNOW WHAT IT'S LIKE TO BE ALONE.

It wasn't always this way.

It used to be hard to decide among all the 35mm SLR's.

Then we created the new Minolta XG-M. A camera so extraordinary it stands alone in its class. With an unrivaled combination of creative features.

First, it's automatic. So it's easy to get sharp, clear pictures. You just point, focus, and shoot. It even has electronic features that keep you from making mistakes.

As your skills advance, you'll appreciate advanced features like metered manual and exposure override for full creative control.

To further separate ourselves from the competition, we built in the option of professional motor-drive. Something normally found only on more expensive cameras.

It lets you shoot a blazing 3.5 frames per second. So you can catch a baseball as it comes off the bat. Or halt a horse leaping a hurdle.

But to fully grasp the XG-M's advanced design, you have to hold it.

The body feels rugged yet light. With a built-in textured grip that's sculpted to fit snugly in your hand. And oversized controls that make it easy to adjust to changing conditions.

As your creative potential develops, you'll have access to over 45 interchangeable, computer-designed Minolta lenses. As well as the Minolta system of SLR accessories.

All in all, the XG-M is a remarkable achievement. But then, we have over 50 years of remarkable achievements to draw on.

The new Minolta XG-M. Now we know how it feels to be alone.

But we're not complaining.

WAIT 'TIL YOU SEE HOW GOOD YOU CAN BE.

If you have a special little niece, a grandson or other favorite child

Give the gift that turns on a child's mind.

The name of this unique gift is HIGHLIGHTS FOR CHILDREN. It is the most honored, and possibly the most beloved, monthly children's magazine in the world. And, in a day and age when fads in toys and trinkets and clothes appear and vanish almost before you turn around, HIGHLIGHTS FOR CHILDREN could be one of the most exciting Christmas presents you will ever give.

For HIGHLIGHTS is not only different from the usual gift, it is different from other children's magazines as well. Its intent is not only to delight and entertain, but to challenge and teach. The editors are nationally known experts in child psychology and family life; they firmly believe that growing children find their greatest pleasure in thinking and creating.

Throughout the year, HIGHLIGHTS FOR CHILDREN brings its young subscribers good fiction and poetry; authoritative articles on science, music, math, nature, space and famous people; craft projects; puzzles, games and just plain fun. It avoids any suggestion of violence or crime in words or pictures. Each issue is 42 or more pages long, bound in sturdy tagboard. The type is large and easy-to-read. There are no coloring or cut-out pages, for HIGHLIGHTS is meant to become part of each young subscriber's permanent library.

HIGHLIGHTS appeals to a wide age range: from tots of 2 who love to listen to its stories and do the simple preparation-for-reading exercises within its pages . . . to 12-year-olds who find the biographies and science articles prime sources for school reports. HIGHLIGHTS helps children develop positive habits that will benefit them as long as they live. The fun-with-a-purpose concept helps children experience success—at home and in school.

For a relatively small price, HIGHLIGHTS brings your love and remembrance to children you treasure . . . not just at Christmas, but all through the year. The contribution HIGHLIGHTS FOR CHILDREN can make to a child's development, however, as it reinforces reading as a pathway to pleasure and information, is a gift that will last a lifetime.

1 year $13.95 (Postage & handling: Canada, $2.50/year; other foreign $3/year.) Gift rate valid to 12/25/81.

latter are carried in llama-hair bags, which weigh about fifty pounds when half full. The bag is draped across the back of the llama, with the salt separated into two equal compartments and tied on with an eight-foot length of thick, braided llama-hair rope. Salt blocks, purchased in pairs, are wrapped in coarse straw (to protect the llama's back) and linked together with strands of llama-hair rope. Draped over the llama and tied on by ropes, two blocks are designated "one cargo" of salt, equivalent to a bag. We took fewer cargoes than animals to allow younger, weaker llamas a respite. Each morning we took care to leave unloaded the half dozen llamas that had been particularly fatigued the previous day, rotating their loads to stronger animals.

A typical day's travel for us averaged six hours, beginning at about 9:30 A.M. and ending at 3:30 P.M., in time for the llamas to graze. Once on the move, we seldom stopped to rest until camp was made. Veteran drovers attempt to pace their daily march so as to reach familiar campsites each afternoon. In addition to pasture, access to water holes and firewood is an important consideration. Only occasionally are there stone corrals in which to herd the animals at night. The lack of corrals complicated our daily chore of loading and unloading the cargoes.

Although a relative of the camel, the shorter llama is always loaded when standing. Only semidomesticated, llamas are not reared from birth to be pack animals. Our llamas were not trained to harness and only partially trained to voice commands, and we had to start, stop, and guide them by flailing a short length of rope, whistling, and making body blocks. The first few days of the journey were a constant battle to prevent the escape of llamas to their home territory, and throughout the trek we were kept constantly busy herding grazing strays back into the main mass of the caravan. Novice pack animals had to be load broken by tying light bundles, such as ponchos or blankets, on their backs.

Our principal morning chore, done right after breakfast, was to load the animals for the day. This we accomplished by a hectic but well-established routine. First, we herded the animals into a compact mass close to the stacked cargoes. A number of pack ropes were then tied together to form one long rope, which was laid on the ground in the form of a large U. Once the animals were herded into this U, the ends of the rope were quickly raised off the ground,

Each year, since 1972, we introduce at least one exciting new travel program; and for the summer of 1982 we offer our first tour into the most ruggedly beautiful, untamed region of Europe:

Adventure in Montenegro

JULY 2 TO 17, 1982

Here, in the dramatic Dinaric Alps of Yugoslavia, our small and expertly led group will spend five nights under canvas and descend the Tara River by log rafts as it flows through pine forests and the huge Dumitor National Park.

Before the thrilling river journey we enjoy five days in historic Dubrovnik and the spectacular Dalmatian coast and visit Montenegro's ancient capital of Cetinje.

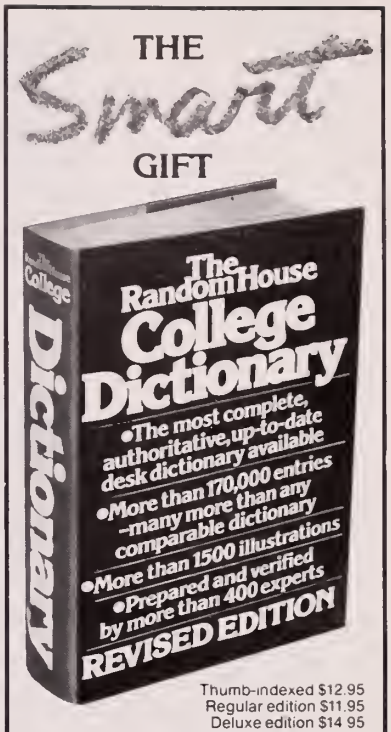
pulled together, and tied. This formed a corral around the mid-sections of the bunched llamas; a second rope was then wrapped around the herd at the knee level. While one of us remained on the outside, circling the corral to prevent escapes, the others climbed inside the ropes and, using shorter pack ropes, linked small groups of adjoining animals by binding their necks together. When all the llamas were bound into clusters of four to six, we could remove the outside restraint ropes and begin the loading. Scurrying back and forth between the stacked cargo and the waiting llamas, each drover tied his loads onto the backs of the pack animals with a slipknot. When a cluster had been loaded, the rope binding their necks was released and they were allowed to graze. Lastly, the camp utensils were loaded on the burros, the llamas united, and the caravan set off for the day. The whole procedure usually took us one hour.

Unloading was done in the same manner until the llamas became habituated. Then it could be accomplished without ropes, simply by forming the animals into a mass and darting in and jerking the slipknots loose with one hand while lifting the cargoes off with the other. This technique enabled us to unload in less than twenty minutes. Once unloaded, the scattered packs and tie ropes had to be gathered and arranged. Each drover on a caravan not only recognizes his own animals but can also identify his own cargo bags and ropes. Each man usually tends to his own tasks before helping a fellow drover with his.

Before being stacked, bags were inspected for holes, tears were sewn, the straw that protected the blocks was redistributed, and frayed ropes were replaced. We then stacked the cargo in piles to form a windbreak, and laid out bedding on the sheltered side. This done, one person was sent for water, while another prepared a crude fireplace. Only then would we take a rest break, eating a snack of flour mixed with water and sugar. Immediately afterward, everyone spread out to gather sagebrush or dried dung for the fire.



Once the sun went down, the winter chill came rapidly upon us. Huddled around the cook's fire, we would eagerly await our first meal since breakfast. For both meals we had *lahua*, a stew made of flour, lard, water, salt, fresh and freeze-dried potatoes, and an occasional slice of carrot or onion. A piece of dried meat bone would be added to the pot for stock. Gregorio and Sergio took turns cooking. The diet was monotonous, but hunger made us lap up the last drop. Supper over, the voluble Sergio would discourse in Aymara until chill or fatigue drove everyone to bed. Once we had left the plateau and entered the eastern Andean mountains through a series of passes, the extreme cold prevented a sound sleep. Intermittently dozing and conversing, we would pass the night. Everyone slept fully clothed, wearing two pairs of pants and a jacket.

On our route we sometimes followed roads passable by truck and bordered by homesteads and fields. At other times we took shortcuts over wind-swept knolls along trails made by years of human and animal passage. Yet even in the coldest, most barren regions, there were signs of human habitation. We observed circular huts of straw or rock used by isolated herders, tiny potato patches tended by aged men, and women carrying infants on their backs in a blanket tied over the shoulder.

As we wound through trails cut through rock crevices so narrow the packs would scrape on either side, we noticed droplets of blood spattered on the rocks. The blood was from llamas whose feet had been cut on the jagged surfaces. At night we would tackle the animals with the worst wounds and treat them. With me holding the animal on its side, Hilario would urinate into a can and pour the urine into the cuts as disinfectant. Gregorio would then use a knife to pry out chunks of gravel from the moistened wound. Once they were cleaned out, he would squeeze daubs of llama lard into the open cuts. Both men would then work together to slip each claw of the cloven hoof through slits in a four-inch square of llama hide. Thongs were then run through holes punched on each corner and the "sandal" was bound to the animal's foot.

On May 31 we began to enter the valley that was our destination, although the transition was not a clear one. Instead, there was a series of canyons that we had to drop into and then climb out of. Morning might find us in a warm, narrow river canyon where peach trees grew, while in the afternoon, we would be a thousand feet above it on a grassy, wind-swept knoll where only flocks of sheep and llamas grazed. Both men and animals being weary, it was with great relief that we reached the temperate valley floor on June 5. Now it was fleas, not the cold, that plagued us at night.

We camped on the banks of the Moscari River, which we followed downstream toward our destination. On June

7 we traveled up a small feeder stream bed and took a narrow, uphill path that led to the hamlet where we would stay and trade. In single file the caravan wound its way up the steep path while we scrambled alongside to fight jams caused by irritated llamas. One would try to crowd ahead of the rest, while another, equally aggressive beast would take offense and begin to spit in the eyes and nip at the neck and ears of the upstart. Until we parted them, the whole trail would be blocked by the combatants. Once, when out of frustration I used blows to separate a group, Sergio chastised me by casually remarking, "Gringo, one must have the patience of Jesus Christ to travel with llamas." Gradually the trail leveled off, and we made camp at dusk, exhausted. The next morning at dawn Sergio discovered that in the darkness he had spread his blankets over an ants' nest.

This hillside was to be our final camp, where the llamas would remain pastured. From then on, one man would stay to guard the camp while the others would visit clients and arrange trades. The burros would be used to transport cargo to and from the houses of the local residents. June 8 was the festival of Corpus Christi, and my companions spent the morning in celebration of our safe arrival.

Sergio and Hilario arose before dawn and went uphill to a rock formation to await the morning sun. There, facing east, they made offerings to the mountain spirits in the morning solitude, burning llama lard, incense, herbs, and coca leaves. On their return they continued their ritual libation of alcohol to the extent that Hilario was sent to buy another bottle. In our journey we had covered some 180 miles in twenty-two days, including seven rest days along the way.

Scattered throughout the canyon we had reached were tiny hamlets, interspersed with farmland and isolated houses wherever the terrain was flat. Thornbush and cactus grew in the dry grasslands that formed the mountainsides, but where there were clearings and water, the soil was rich in vegetation. People were at work in the fields trimming ears of corn off dried stalks or cutting other stalks to dry. Cattle used for plowing were tethered in fields of stubble. Near people's homes were large trees on whose lower forks stalks of maize were stored for fodder. Next to the plots of maize were smaller ones of broad beans, peas, and squash.

Before the development of motor

roads, llama caravans were the only outlet for surplus maize. Valley residents require salt for themselves, their draft animals, and goats. According to the drovers, the valley people are also anxious to trade their yearly surplus because insect larvae infest stored maize and render it fit only to feed to chickens and pigs. In contrast, on the arid plateau, maize, freeze-dried potatoes, and quinoa can be stored for years.

When a caravan arrives, valley people are generally busy with the harvest, and so they expect the drovers to shell their own maize. After the trade has been agreed on, a drover enters his client's patio and is presented with mounds of dried ears to shell. He spreads the ears over a blanket and, with bare feet, treads them vigorously to snap off the dried kernels. If the maize is still wet, then the kernels must be rubbed off by spindling the ears between the palms of the hand. The friction that results causes sores and even bleeding. This and the shrinkage that occurs as the maize dries explain why drovers will delay their departure from the valley until the end of June rather than accept water-soaked maize in trade. While it might seem to be burdensome for drovers to shell their own maize, they have the advantage of choosing the quality of ears to shell.

Those who still travel with llamas are mainly pastoralists who lack money for truck fare or market purchase. The beneficial exchange rate they enjoy also motivates them: "With llamas there is no transportation charge, only physical suffering—work. In the market, when you buy maize you get an exact weight. When we trade, it is done by estimate, and we always get an extra amount."

In remote areas frequented by llama caravans, traditional forms of measurement by volume are still used. At present, salt is traded on a volume-for-volume basis. If the harvest is good, the valley people will be especially generous with their surplus to compensate for the bad years, when they cannot reciprocate adequately for the cargoes of salt. When the maize is plentiful, the llamas return burdened to capacity, and sometimes fatigued llamas weaken and die.

Nineteen seventy-seven, however, was one of the poorer years, and when Sergio, Gregorio, and Hilario set off on July 12 for the return trip to Pampa Aullagas, they were not enthusiastic about the results of their venture. Although they returned with other foodstuffs as well, they were particularly dissatisfied with the amount of corn

Celestron® Multipurpose Telephotos

Let You Reach Out...

A long focal length telephoto lens is irreplaceable for many aspects of sports, nature and action photography—there are many times when only a "long" lens can achieve the right framing, isolate a subject against a complex background or provide the image scale you want for dramatic, artistic photographs.

Only Celestron offers a complete range of compact, mirror-lens telephoto lenses of 300 to 3910mm focal lengths that can also be used as visual spotting scopes and high quality, large aperture astronomical telescopes.

You are invited to see the multipurpose Celestrons at your local camera dealer and to learn about the full potential of a Celestron by sending for our beautiful, full-color, 52-page catalog describing our complete telephoto, astronomical telescope and binocular lines.

You'll be surprised at how little a Celestron costs—far, far below equivalent, bulky conventional telephoto lenses that have none of the versatility of a Celestron.

To capture the unusual
Celestron 750mm f/6 Photograph

Free 8-page brochure or send $3.00 for 52-page full-color catalog on how to select and use a Celestron telescope/telephoto lens.

American Museum of Natural History
Discovery Tours

GALAPAGOS ISLANDS CRUISE
June 5-17, 1982

Discover a naturalist's paradise: a volcanic archipelago straddling the equator and home to unique and tame animals. Share a relaxed holiday aboard the comfortable M.V. Buccaneer with three American Museum curators—all experts in their fields; ornithology/ecology, geology/volcanology, herpetology/evolution. Enjoy superb climate, sandy beaches, fantastic photographic opportunities, and good company. Limited to 65 passengers. For further information write to DISCOVERY TOURS, American Museum of Natural History, Central Park West at 79th Street, New York, NY 10024, or call (212) 873-1440.

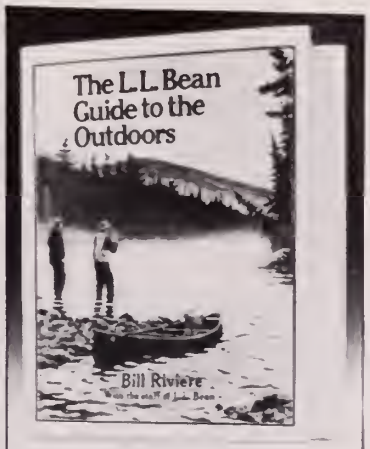
Terry L. West

On the caravan accompanied by the author, above, there were fifty-five llamas, as well as three burros to carry utensils and provisions. Loads were rotated each day so that fatigued llamas could have a respite.

they had acquired: Sergio had fourteen cargoes of corn (700 pounds) and Gregorio only ten. Hilario declared his intention to work in Santa Cruz the next year and purchase maize in the valley with part of his earnings. None of them planned to travel with llamas any more.

Archeological evidence indicates that llama caravans existed in the Andes almost 4,000 years ago, but the system of interdependence that has for so long operated between highland drovers and their valley trade partners is breaking down under the impact of commercialism. Markets have eroded the barter system that prevailed for centuries, and middlemen, traveling in trucks and buying maize with cash, have forced down the exchange rates, which once were more favorable to drovers.

Traditionally, the primary goal of all drovers was the provisioning of their households, not monetary gain; they were concerned with the quantities of products traded, rather than their monetary values. This ideal is reflected in the traders' custom of not mentioning the cash value of exchange items during their transactions. Lately, however, migrant labor opportunities created by an



agricultural boom in the Department of Santa Cruz have induced the new generation to take a more calculating look at the economics of llama caravans. The young men of Pampa Aullagas do not consider the profits sufficient compensation for the effort that must be expended. They can earn enough as wage laborers in the same amount of time to buy the maize they need and still have money to spare.

While recent increases in the price of oil in some Andean regions appear to have given llama transport a new lease on life, there are other considerations that spell a permanent decline in the caravans of Pampa Aullagas. Following the introduction of tractors in 1972, agricultural production rose as lands formerly used for grazing were opened up to cultivation. This both reduced the need for llama ownership and constricted the amount of pastureland. About the same time, some local residents purchased large trucks, which are a more convenient form of transportation to the valleys, as well as to the nearby weekly market where maize and other valley products can be purchased. Finally, the construction of a secondary school has helped to deprive drovers of their apprentice helpers. Exposed to the opportunities and values of modern society, the youth of Pampa Aullagas have become both independent and disdainful of their parents' occupations. Many hope to be teachers or truck drivers or at least migrant workers, to earn money and emulate urban ways. To travel with or herd llamas is to them old-fashioned and even degrading. □

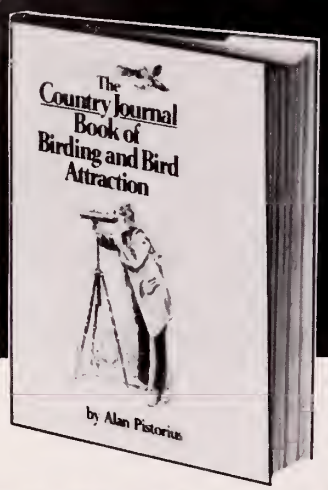
Enter the world of Questers nature tours.

Stimulate your mind on a Questers tour.

We search out the plants and animals, birds and flowers... and explore the rain forests, mountains and tundra, seashores, lakes and swamps. Tours are under the leadership of a naturalist, and range from 9 to 35 days. There is ample time to photograph, absorb, reflect. Tour parties are small, accommodations are first class, and all meals are included.



The current Directory of Worldwide Nature Tours describes tours to: *In Africa*—Zimbabwe, Botswana, Kenya. *In Asia*—India, Nepal, Bhutan, Sri Lanka. *In Australasia*—New Zealand, Australia. *In Europe*—Iceland, Greece, Spain, Switzerland, Scotland. *In the Americas*—Everglades, Alaska, Baja California, Hawaii, Pacific Northwest, Costa Rica, Panama, Amazon, Patagonia, Galapagos.

Write today for a free copy of the Directory of Worldwide Nature Tours.

Meshie Mungkut

In February of 1930, Harry Raven, a curator at the American Museum of Natural History, had just finished lunch in his camp in the great forest of the French Cameroons when two Africans emerged from the bush and approached him. One man carried a baby female chimpanzee in his arms. The African explained that he had shot the mother with a poisoned dart for food, and when he retrieved the body he had found the terrified infant chimp clinging to the dead mother's hair. The African had kept the animal as a pet for about a month and wanted to know if Raven was interested in buying it.

"I approached the man who held her," Raven wrote later, "and put out my arms. The little animal looked at me a moment, then stretched her arms toward me and I took her. She grasped me tightly as if she might fall." Raven bargained with the man through an interpreter and after much haggling acquired the chimpanzee. This purchase marked the beginning of one of the first attempts to raise a chimpanzee as a child in a human family.

Raven kept the chimp with him while the Museum expedition he was on traveled for more than 2,000 miles in Africa. When Raven returned to his temporary house in the Cameroons, he let the chimp have free run of the town. She played with the local children, who began calling her Meshie Mungkut, which loosely translates as "little chimpanzee that fluffs her hair up to look big."

In a year Raven's work in Africa was finished, and he took Meshie across the Atlantic in a steamship. One cold February day in 1931 they arrived in Boston. According to Raven, "Meshie was very much excited and interested in the things she saw and heard. I think the outstanding incident of Meshie's arrival in the United States was her alarm on seeing a team of horses while she was being driven across Boston in a taxicab. . . . Upon seeing a team of great dappled gray draft horses blowing clouds of steam through their nostrils, she uttered a little scream and grabbed me around the neck. . . . Meshie actually got down on the floor once in an effort to get as far away as possible, but a moment later she was back looking out the window."

Anthropologist Harry Shapiro, a colleague of Raven's in the Museum, who is now curator emeritus, recalls Meshie's life with the Ravens.

"Harry [Raven] arrived at his house one winter's evening. After the first greetings with his wife and children, he reached into a large pouch and pulled out the baby chimp. Harry treated Meshie just like another child in his family and raised her accordingly. The Raven kids, well, they treated her as a sibling.

"It wasn't a scientific experiment, mind you, but as far as I know this was the first time a chimpanzee was raised as a human. Of course, there have been

Meshie's mounted body on display in the Hall of Primates

Ownership Statement

Statement of ownership, management, and circulation (required by 39 U.S.C. 3685) of *Natural History*, published twelve times a year at the American Museum of Natural History, Central Park West at 79th Street, New York, N.Y. 10024, for October 1, 1981. General business offices of the publisher are located at Central Park West at 79th Street, New York, N.Y. 10024. Publisher, David D. Ryus; editor, Alan P. Ternes, Central Park West at 79th Street, New York, N.Y. 10024. Owner is the American Museum of Natural History, Central Park West at 79th Street, New York, N.Y. 10024. Known bondholders, mortgagees, and other security holders owning or holding one percent or more of total amount of bonds, mortgages, or other securities: None. The purpose, function, and non-profit status of this organization and the exempt status for federal income tax purposes have not changed during preceding 12 months (Section 132.122, Postal Service Manual).. The average number of copies of each issue during the preceding 12 months are: A. Total number of copies printed: 500,048; B. Paid circulation: 1. Sales through dealers and carriers, street vendors, and counter sales: 11,699; 2. Mail subscriptions: 453,813; C. Total paid circulation: 465,512. D. Free distribution by mail, carrier, or other means: 6,708. E. Total distribution: 472,220. F. Copies not distributed: 1. Office use, leftover, unaccounted, spoiled after printing: 9,529. 2. Returns from news agents: 18,299. G. Total: 500,048. The actual number of copies of single issue published nearest to filing date are: A. Total number of copies printed: 503,642. B. Paid circulation: 1. Sales through dealers and carriers, street vendors, and counter sales: 13,135. 2. Mail subscriptions: 455,382. C. Total paid circulation: 468,517. D. Free distribution by mail, carrier, or other means: 6,971. E. Total distribution: 475,488. F. Copies not distributed: 1. Office use, leftover, unaccounted, spoiled after printing: 7,609. 2. Returns from news agents: 20,545. G. Total: 503,642. I certify that the statements made by me above are correct and complete.

David D. Ryus, Publisher

many such experiments since. We were all just fascinated with how 'human' this chimp was. She did all the little things that human children do—she was socialized as a human child."

In his backyard, Raven built Meshie a house that consisted of a box attached to the top crossbar of a swing set. The box had a sliding door and stood eight feet off the ground, as chimpanzees, being arboreal, are nervous about sleeping near or on the ground. Every evening Raven stood under the house holding a pile of blankets, and Meshie leaned out the door and caught them one by one as he tossed them up. Inside the house the chimp twisted the blankets into a nest, and in the morning, upon rising, she carefully dropped the blankets one by one to the ground.

Meshie was a habitué of the Museum, where she was a model visitor. "She would ride around," Shapiro recalls, "on a tricycle through the long fifth-floor halls. At lunchtime she would go down the elevators and eat with us in the old staff dining room. She had perfect manners and always ate with a knife and fork, although she sometimes was a little impatient with the waitress. I remember one extraordinary incident in particular. I was having lunch with Harry and Meshie, and after eating Harry got out a cigarette and put it in his mouth. He turned to Meshie and tossed a book of matches in front of her, saying, 'Meshie, light my cigarette.' Meshie sat there and looked at the matchbook. Harry repeated his order in a very strict, firm voice. This time Meshie picked up the matches, then dropped them in fright. Harry again repeated the order, and this time Meshie picked up the matches and took out a match before dropping them in fear. She obviously knew what the matches were and was afraid of fire. Finally, after Harry insisted several more times, Meshie lit his cigarette."

Raven made a silent film of Meshie that shows the chimp's daily activities at the Raven household. Meshie is seen pulling a sled, bouncing on a bed with the Raven children, eating with a spoon and drinking with a straw, riding a tricy-

Bagpipes Call Our Men
To Battle. We Also have Something
To Call Them home.

The first bagpipes were intended to strike fear into the hearts of our enemies.

Our own brave men, however, found the sound a source of pride and inspiration. Let the piper skirl and we feel moved to march off to just about anyplace.

But then we have powerful calls to return home, too. One of which is a scotch that whispers. J&B Rare Scotch is specially and selectively blended to have a most agreeable and pleasant taste.

It's carefully chosen from the finest whisky in the land.

Why did we create a scotch that whispers? Well because, you can't spend a quiet evening with a bagpipe.

To send a gift of J&B (bottle or case) anywhere in the continental U.S.* call: 1-800-528-6148.

J&B. It whispers.

Better Than Jogging

NordicTrack

Jarless Total Body Cardiovascular Exerciser

Duplicates X-C Skiing for the Best Motion in Fitness

Highly Effective and Pleasant To Use
The enjoyable sport of cross-country skiing is often cited as the most perfect form of cardiovascular exercise for both men and women. Its smooth, fluid, total body motion uniformly exercises more muscles and higher heart rates seem easier to attain than when jogging or cycling. NordicTrack closely simulates the same pleasant motion and provides the same cardiovascular endurance-building benefits — right in the convenience of your home. Makes a year round, consistent exercise program easily attainable. Eliminates the usual barriers of time, weather, chance of injury, etc. Also highly effective for weight control.

Better Than Running
NordicTrack gives you a more complete work out — conditions both upper body and lower body muscles at the same time. Fluid, jarless motion will not cause joint or back pains as jogging or running often does.

Better Than Exercise Bikes
NordicTracks stand-up skiing motion more uniformly exercises large leg muscles and also adds important upper body exercise. Higher pulse rates, necessary for building fitness, seem easier to attain because the work is shared by more muscle mass. The NordicTrack also keeps more muscles in tone.

Even Better Than Swimming
NordicTrack more effectively exercises the largest muscles in the body, those located in the legs and buttocks. These muscles main function is to lift and propel the body in the standing position. When swimming, the water supports the body thus preventing these muscles from being exercised as effectively as when they support the body in a standing position as when using the NordicTrack.

A Proven, high Quality Durable Product
Ruggedly constructed, NordicTrack is quiet, motorless and folds compactly for storage. Separate arm and leg resistances. NordicTrack is in its 5th year of production and is used in thousands of homes and many companies. We manufacture and sell direct. Our No-Risk 15 day trial guarantee shows our confidence in your being pleased with the performance and quality of the NordicTrack.

cle around the neighborhood, taking a bubble bath, playing tug of war, and squirting water from a hose into the upper-story windows of the Raven house. In one sequence, Meshie picks up a baby in the family, carefully carries her to a high chair, brings over her food in a bowl, and feeds her with a spoon. After the baby is finished eating, Meshie fetches a damp cloth and neatly wipes clean the baby's tray. Meshie was adept at escaping from any kind of cage or leash, and one sequence in the film shows her untying herself from a tree by loosening the knot with her teeth, pulling open the knot's loop, climbing through the loop, and scurrying away. If the rope were double- or triple-knotted, she would simply climb through the knot's loops several times, a rather sophisticated piece of topological reasoning. Meshie also learned how to open a padlock by packing it with sand, how to break an iron chain by knotting it and then pulling, and how to remove leather collars by wetting them over and over again with her tongue until they became brittle. If put in a cage, she would endeavor, sometimes with success, to pry or bash her way out. In many ways Meshie was curiously "human." In the movie, for example, she walks upright most of the time instead of walking with her knuckles on the ground. And Raven reported that, like many New Yorkers, the chimp had a pasty white complexion in winter but tanned a rich brown in the summer.

Exactly how much coaching Meshie got in performing many of her tricks is unclear, but it was considerable. If primatologists were to study the movie today (none have, surprisingly enough), they probably would disagree about how much Meshie was being "cued" and to what extent her actions were simply imitative. But no one would disagree that Meshie led an extraordinary life for a chimpanzee—or even for a human. Meshie lunched with many prominent citizens, including Museum president Henry Fairfield Osborn, Mr. and Mrs. Ralph Pulitzer, and the novelist Edna Ferber. The high point of the chimp's social career in New York was described by Raven in 1933:

> Not long ago Meshie had the honor of being the guest of President F. Trubee Davidson of the American Museum of Natural History at a formal banquet at the Waldorf-Astoria. What could be stranger, more unlike her former home in the African forest, than the ride across Manhattan in a taxicab, the brightly lighted hotel with the gaily-dressed people everywhere, the brass band and Negro minstrels! But she rode her kiddie car through the foyer, into the banquet hall crowded with strangers, and took her place at the table with the rest of the guests. She politely ate some of each course as the dinner was served, sat quietly while the speeches were made, blinked while the press photographers took more than a dozen flash-light photographs of her, and did not get home until long after midnight.

Meshie spent about five years with the Ravens in their Long Island home. Her final year with them was one of increasing difficulty, according to Shapiro:

"When Meshie became sexually mature at about six years old she became a real problem. Meshie thought of Harry as her father, and he was really the only one who could control her. Mrs. Raven often had to call Harry at the Museum because of Meshie, and he would have to rush home. They didn't know what to do. Finally Mrs. Raven insisted that Meshie go, and so they sold her to a zoo in Chicago.

"About a year or so later I ran into Harry in the hall at the Museum. He was very upset. He told me he had been passing through Chicago and decided to see Meshie at the zoo. The zookeeper warned him that Meshie had become absolutely wild and dangerous. Sure enough, as Harry approached her cage he could hear her screaming and banging on the bars and carrying on. The zookeeper didn't want to let Harry go into the cage, but he insisted. When he went in, Meshie rushed into his arms and clung to him tightly. Tears were streaming down her face."

Meshie died in childbirth a year later, and the zoo shipped her body back to the Museum, where it was mounted and put on display in the Hall of Primates. No label indicates the animal's identity, but it is said that Raven stopped by the hall once in a while and gazed thoughtfully at the stuffed chimp with the glass eyes. "I suppose," said Shapiro, "it was kind of a memorial for him."

Douglas J. Preston

Harry Shapiro will introduce and show the film about Meshie made by Harry Raven in the 1930s in a special program open only to Museum members. *Bringing up Meshie* will take place on Wednesday, December 16, at 7:30 P.M. in the Museum's Auditorium. The program is free, but advance tickets are required. Call the Membership Office at (212) 873-1327 for ticket availability.

Reality behind Myth

Claireve Grandjouan, professor of classics and a popular Museum lecturer, will give an illustrated talk, *Land and Gods*, on Wednesday, December 2, at 7:00 P.M. in the Auditorium. The lecture will explore the relationship between nature and the personalities of many ancient Greek and other Mediterranean gods, including Baal, Zeus, Vulcan, and Bacchus. Tickets for the evening are $5 for members and $6 for nonmembers and may be purchased in advance from the Museum's Education Department.

Vanishing Jungle

The tropical rain forest, popularly known as the jungle, is the focus of a symposium at the Museum on Wednesday, December 9, from 6:00 to 8:00 P.M. in the Auditorium. Three speakers will discuss the future of the earth's great rain forests, where about half of all animal and plant species live. Moderator Russell E. Train, president of the World Wildlife Fund-U.S., will be joined by Thomas Lovejoy, Ghillean Prance, and George Woodwell in a program of slides and discussions about the threatened ecologies of the rain forest. Tickets are $6 for members and students and $8 for nonmembers.

Swamp, Ocean, and Fig

New Natural History Films is the title of a free weekend program on December 5 and 6. Three new films will be shown in the Auditorium on both Saturday and Sunday at 1:00, 2:00, and 3:00 P.M. At 1:00 P.M., *Pantanal*, a film about the 100,000-square-kilometer marsh south of Brazil's Matto Grosso, will be shown. At 2:00 P.M., *Dive to the Edge of Creation* takes the viewer down to the mid-oceanic ridges where hot water vents and a sulphur-rich solution support a variety of unusal, nonphotosynthetic life forms. *Amate*, a film about an ancient fig tree, its life cycle and microhabitat, will be shown at 3:00 P.M.

Carved Birds

An exhibition of exquisitely carved birds is currently on display in the Roosevelt Rotunda. Created by Mary and Porter Brown, the life-sized birds are hand-carved of basswood and are accurate down to the fine details of individual feathers. The exhibition also includes carving tools and information on how the birds were carved. The Browns' work was recently featured in an article in *Sports Illustrated*.

Haitian Highlights

On the weekend of December 5 and 6, a program of Haitian arts, crafts, folk dances, and music, including a lecture by Henry Frank on voodoo, will be presented in the People Center. Entitled *Panorama of Haiti*, the free program, presented by the Education Department, runs from 1:30 to 4:00 P.M. on both days.

Caribbean Christmas

The celebration of Christmas in the Caribbean is the focus of a free program in the People Center on December 12 and 13. This Education Department program, which includes folk music and dance, and arts and crafts in different areas of the Caribbean, runs continuously from 1:30 to 4:00 P.M. on both days.

Dance Potpourri

The Allnations Dance Company, a multiethnic troupe, will give a free performance on Sunday, December 13, at 2:00 P.M. in the Auditorium. In a program entitled *Joy in Every Land*, the troupe will perform dances from Appalachia, Mexico, China, Tahiti, Barbados, the Philippines, and Kenya, among other places.

For more information about programs or events, contact the appropriate Museum department: Education Department (212) 873-7507; Membership Department (212) 873-1327; Hayden Planetarium (212) 873-1300, ext. 389; or write to the department at the American Museum of Natural History, Central Park West at 79th Street, New York, N.Y. 10024

Any project worth starting is worth finishing with Behlen.

Quality woodwork deserves a quality finish. That's why, since 1888, the world's foremost professional finishers and cabinetmakers have insisted on H. Behlen & Bros. Finishing Products.

Now you can do the same. Because, although normally available only in industrial quantities, Behlen finishing supplies can now be ordered from Garrett Wade in quantities packaged for the amateur or small professional shop.

Our extensive selection of Behlen products includes:

- Removers
- Burn-in Sticks
- Aniline Dyes
- Pigment Stains
- Coloring Agents
- Varnishes
- Lacquers
- Shellac Flakes
- Rubbing Materials
- Oil Finishes
- Waxes
- Brushes & Cleaners
- Bleaches
- Padding Lacquers

By using only the purest, most carefully selected ingredients, Behlen products take the mystery out of obtaining professional finishing results—and add the perfect "finishing touch" to all your wood-working projects.

Camera-ready art is required for display ads. A tearsheet or copy of the page with your ad will be sent upon publication.

Celestial Events

by Thomas D. Nicholson

The Moon The four-day-old crescent moon of December 1 is in Capricornus and grows to first-quarter on December 4. The moon is in Taurus when it is full on December 10, and the bright reddish star to its right is Aldebaran. On the night of the 12th, the gibbous moon is below the stars Castor and Pollux in Gemini, and on the 15th it passes above Regulus, in Leo. Last-quarter moon is in Libra on the 18th, located just above the autumnal equinox when it rises about midnight on the 17th. The waning crescent passes Mars on the 18th, Saturn and Spica on the 19th, and Jupiter on the 21st. It will be seen near them in the morning sky for several days. After new moon early on December 26, the crescent moon of the new cycle should show up in the evening sky by the night of the 28th, when it passes near Venus. Perigee moon (nearest the earth) is on December 10 and January 8; apogee moon (farthest from the earth) is on December 23 and January 20.

Stars and Planets Mars, Saturn, Spica, and Jupiter, which rise in that order from midnight on, offer a spectacular show in the morning sky, although Jupiter's motion to the east has stretched November's triangle out quite a bit. Look for these objects from about 4:00 A.M., when they should be clear of the horizon's murk, until dawn wipes them out. Note that Jupiter has now shifted well to the left of Virgo's bright star Spica, while Mars is moving swiftly toward both Saturn and Spica. Saturn, meantime, has pulled much closer to Spica, but hasn't yet passed to its left. It will pass it in early January, in late February, and again in September 1982, and then not for another thirty years. Can you guess why? I'll tell you about it in the January *Natural History*. Mercury, you may remember, was part of the Saturn, Spica, Jupiter scene last month, but it has stayed close to the sun (actually moved closer to it) while both have moved rapidly away from Virgo. On December 10, Mercury passes the sun, on the far side as seen from the earth, in the position called superior conjunction. The planet then enters the evening sky, but remains too close to the sun (setting very soon after sundown) to be seen for the rest of December and early January.

December 10: Mercury, in superior conjunction, enters the evening sky.

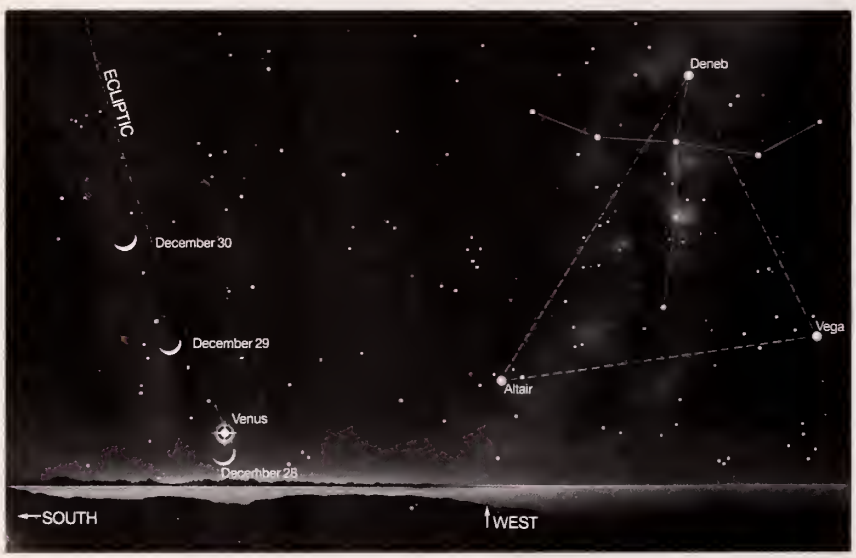
December 11: With perigee moon on the 10th and full moon only nine hours later on the 11th, tides should be exceptionally strong today and tonight as the effect of perigee adds to the normally stronger spring tide that accompanies syzygy twice each month (at full and new moon).

December 13–14: The normally productive Geminid meteor shower, one of the two best of the year, reaches maximum tonight. Since the full moon occurred only two nights ago, the still bright waning gibbous moon will obscure all but exceptional objects. Unfortunately, the Geminids seldom produce bright meteors.

December 16: Venus, moving closer to earth, has been brightening rapidly, but also showing less of its sunlit surface. The best balance occurs today, and Venus reaches its greatest brilliancy in our sky.

December 18–21: Watch the waning crescent moon move past the planets in our morning sky, highlighting each in turn. The moon is nearest Mars on the 18th, Saturn on the morning of the 20th, and Jupiter on the 21st. Look for them from 4:00 A.M. on, in the east.

December 21: The sun arrives at the winter solstice today, and winter begins in the Northern Hemisphere. This is also the shortest day of the year, although the earliest sunset occurred on the 9th and the latest sunrise will be about January 4.



December 21–22: The Ursid meteor shower (about 15 per hour) reaches maximum after midnight.

December 28: Venus is just above the crescent moon tonight. On the 30th, the planet begins its retrograde (westerly) motion.

January 4: Earth is at perihelion, nearest to the sun (about 147,102,000 kilometers, or 91,405,000 miles, distant).

January 8: Saturn is in conjunction with Spica.

Editor's Note: The Celestial Events Sky Map in the October issue shows the evening constellations and stars for this month and gives the times for use.

Helmut Wimmer

Venus is the only bright evening planet in December, visible low in the west-southwest shortly after sundown. This hasn't been a good evening cycle for the planet, however, since it is too far south and its position relative to the sun at setting keeps it low in the sky. The view of Venus improves in late December, as its position to the sun's east brings it to the northerly curving part of the ecliptic. The early crescent moon passes above Venus on the night of the 28th, as shown here, at about 6:00 to 6:30 P.M.

Give a GIFT of NATURAL HISTORY

Give one at $15 and save 20% on subsequent gifts at $12 each

This Christmas give 12 beautiful, thought-provoking issues of Natural History to someone special. This year-long gift is appreciated by discriminating and intelligent people, and is inexpensive and easy to order. Just send this postage paid card with your order today.

An Art Book That Took Centuries To Create

It took the American Museum of Natural History four years to arrange its exceptional exhibition of more than 500 pieces of ancient gold from Colombia. But those few years are a brief time when compared with the decades archeologists have spent digging (literally!) and studying the gold artifacts from tombs, caves, and buried sites. And all that time is short when compared with the many centuries prehistoric Indians practiced their craftsmanship and artistry to create these treasures.

So when it became the United States sponsor for this outstanding collection, the American Museum faced a dilemma. Could we do justice to all this effort and scholarship and beauty? We think we have. First, by dramatically displaying *Gold of El Dorado: The Heritage of Colombia* in one of our largest halls. The glowing reports from visitors tell us our efforts have been worthwhile. If you don't have a chance to see the show for yourself in New York, we hope you will see it in Chicago, San Francisco, or New Orleans on its year and a half tour.

The second challenge for the American Museum was the creation of an appropriate book to accompany the exhibition. We decided against a traditional catalog; against a small, boring volume with tiny black-and-white pictures that could never do justice to these fine objects. Instead, we decided to present a select number of the finest pieces of pre-Columbian gold in a large, stunning format. And to represent the three important elements that make a great art book we chose outstanding professionals.

First, photographer Lee Boltin. One of the greatest photographers of art objects, he also took the famous pictures of the Tutankhamun show. We sent him abroad to find and record great pieces of pre-Columbian art.

Second, archeologist Warwick Bray, from the University of London. One of the world's foremost authorities on pre-Columbian art, Bray is also a skilled writer, able to present fascinating background in a succinct, readable essay in the book. Dr. Bray organized the Colombian gold exhibition in London.

Third, Harry N. Abrams, Inc., America's leading publisher of fine art books. In a co-publishing venture with the American Museum, Abrams designed the book, supervised the preparation of 30 large color plates, and monitored the fine-quality printing.

The result is an unprecedented exhibition book. It is bold and big—each plate is 16 by 11½ inches—bigger than this magazine *opened up*. The paper is heavier than most posters. In fact, many persons have purchased two copies of the book in order to have one set of these fine art prints for framing.

And now for the happy ending. Because the Museum is a co-publisher, we are able to offer this soft-bound art book at a major savings from its normal retail price of $12.50. We are pleased to offer *Gold of El Dorado* to subscribers for only $6.25—a 50% savings off its regular price. This special offer is valid only during the exhibition and only while our limited supply lasts. We suggest that you order one or more copies immediately. Of course, if you are not satisfied after you have had an opportunity to examine it in your home, simply return the book and the Museum will refund the purchase price.

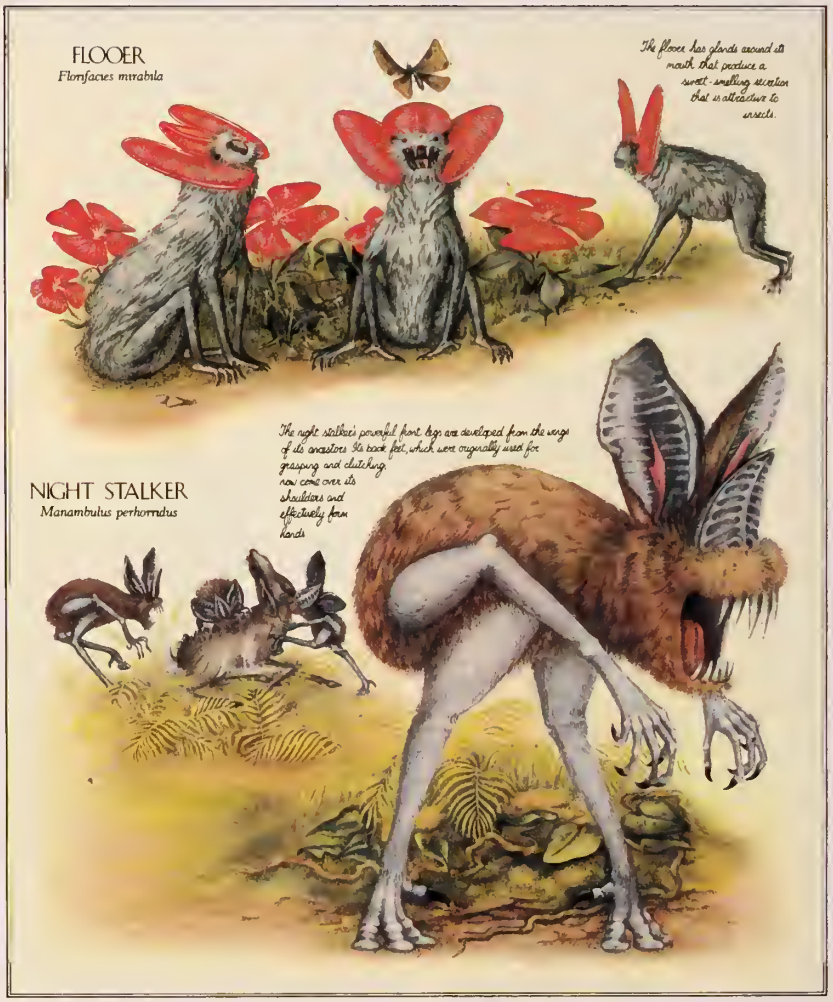
Striger, Striger, Burning Dim

by Matt Cartmill

AFTER MAN: A ZOOLOGY OF THE FUTURE, by Dougal Dixon. *St. Martin's Press, $14.95; 124 pp., illus.*



The animal I wanted
Couldn't get into the world . . .
I can hear it crying
When I sit like this apart from life.
Kenneth Patchen

Dougal Dixon wants *lots* of animals that never made it into the world. Giant killer rats with incisors like interlocking sickles. Naked pink sea lion things that swim through desert sand like dusty sharks. Big spotted bunny rabbits with the long necks and dainty hooves of gazelles. Rodent ostriches, feathered whales, blind wingless bats the size of Volkswagens: he dreams about them, draws them, sculpts them, makes up classifications and pedigrees for them. In this amusing and disturbing book, he marshals his imaginary zoo for its first parade in public.

After Man has a certain obsessive quality to it, which is one of the things that make it disturbing. God only knows what a psychoanalytic reviewer would make of it, although a few choice Freudian symbols are obvious to anyone (for example, the recurrent image of a yawning, toothy mouth set in an eyeless face). But although some of Dixon's creatures are frankly nightmarish, and the book's format and illustrations seem to be aimed at the people who buy those coffee-table books on the natural history of trolls, *After Man* is not just another dreary exercise in fantasy-world construction. It aspires to be both an imaginative entertainment and a textbook of sorts on the principles of evolutionary biology.

Dixon, a former paleontology student turned animator and pop-science writer, offers us a minutely detailed vision of what the world might look like fifty million years from now. He makes three basic assumptions. The first and simplest is that the continents are going to keep on drifting along their present courses, producing a new world map with differently arranged habitats. The second is that *Homo sapiens* is going to become extinct in the near future, when shortages of food, land, and raw materials demolish the fragile industrial economy that we all depend on (he says) for survival. The third is that most of today's large mammals—whales, elephants, cats, dogs, horses—will either be wiped out by our death throes or sucked down to oblivion along with us and our pet-food canneries. This third assumption is the critical one, because it leaves lots of empty niches waiting to be filled by the rats and rabbits and reptiles that creep out to stare at our ruins.

The book's first thirty-two pages are devoted to reality. Dixon gives us a survey of the ground rules of his evolutionary game—genetics, ecology, ethology, convergence, mimicry, Bergmann's rule, and so on—and a 6,000-word synopsis of The Story Thus Far, from the Precambrian up through the history of

Bats that have taken up a terrestrial life are the flooer, an insect-eater, and the night stalker, which devours mammals and reptiles indiscriminately.

man and his well-deserved extinction. This part of the book is drably printed in black and uremic yellow on a matte paper. We turn the page and find ourselves in a four-color fantasy printed on glossy stock, full of gorgeous landscapes and delightful paintings of charmingly named animals: flapjacks, gholes, spickles, wakkas. The effect is exactly like the transition from Kansas to Oz in the old MGM *Wizard of Oz* (Dixon, remember, is a filmmaker on the side), and the subliminal message is similar: Oz, witches and all, is better than Kansas, and a fantasy world without intelligent life is better than a real world full of human beings.

This is the main reason why I found *After Man* so disturbing. For all its lovely artwork (including several witty parodies of Audubon and his successors), unflagging inventiveness, and genuine educational value, the book oozes a black misanthropy that is ultimately self-destructive. Asked in a recent television interview why he had omitted intelligent life from his zoology of the future, Dixon replied, "I take the line that Nature won't make that mistake twice." The same moral is conveyed in Dixon's book: sentience is a blind alley, and thinking leads to extinction. This sentiment seems out of place in a book that aims to teach nonscientists the principles of evolutionary biology. Telling your audience that science and learning are suicidal is a poor way to arouse their enthusiasm for learning something about science. Even on a superficial level, Dixon's zoology of the mindless future contradicts itself, for the reader soon starts to wonder just who or what is supposed to be describing these animals and giving them scientific names—in Latin, yet—if the last scientists died fifty million years before. "The purrip bat," Dixon tells us on page 46, is "so called because of its curious voice." So called by *whom*?

The pilofile's bristles extend its potential insect-catching area beyond the region of its head

SRI LANKA

The island of Serendip in the Indian Ocean better known to you as Sri Lanka or Ceylon offers you the most unexpected discoveries.

You will see in this resplendent land one of the world's oldest cultures and marvel at its ancient cities, built before Rome was founded.

Optional excursions to the architectural splendors of North & South India and the Himalayan Kingdom of Nepal; the coral formations and tropical atolls of Maldive Islands, wild life parks where you can see leopard, the rare black deer, loris, elephant and various other species of animals and birds; golden unspoiled beaches of Bentota and Trincomalee.

Desmond Morris, in his introduction to *After Man*, compares Dixon's creations favorably to what he calls "the cheaper brands of Science Fiction." But cheap or high-priced, any competent science fiction writer knows that a world without sentient life or the hope of sentience to come makes for a boring, meaningless, and ultimately depressing story. (Compare Dixon's book with De Camp and Miller's exhilarating science fiction bonbon *Genus Homo*, which is also set in a post-human future full of giant bats and gazellified rabbits, but contains *five* plausible sorts of thinking animal—four primates and a beaver.) The human species is the only mind our planet has. Although a world without other animals would be as disturbing and repulsive as that living brain in a bottle that Orwell took to be "the logical end of mechanical progress," Dixon's fantasy world without the promise of intellect is a living body with a dead brain—futile, empty, and hopeless. And that, unfortunately, has to be the coroner's verdict on *After Man* considered simply as a work of imaginative fiction.

And as a work of scientific speculation? Considered as science, Dixon's book has real merits and equally real flaws. Both are interesting because they suggest some larger thoughts about evolutionary biology.

A lot of Dixon's imaginary animals are genuinely plausible—so plausible that it's hard to see why they should be imaginary. Take, for instance, his giant rabbits ("rabbucks") that have replaced the missing deer and buffalo. This sounds like a sure bet; rabbits and hares have convoluted guts, high-crowned teeth, and a nasty but practical habit of recycling their feces, and so they look like logical candidates for the hayburners of a future without horses and cows. Well, then why aren't there *already* rabbits the size of deer or, anyway, of small antelopes? Why haven't the rabbits ever produced a herbivore that weighed more than about fifteen pounds? Some of Dixon's other good ideas raise similar questions. Monkeys with skinfold "wings" like a flying squirrel's? Sure—but why haven't there ever been any gliding primates? Fish-eating mammals with long, many-jointed necks like a heron's or a plesiosaur's? Seems reasonable—but then why has almost every mammal for the last 150 million years or so had seven vertebrae in its neck? (A few have six; one genus of sloths has nine.) Why haven't the marsupials, some of which have been running around in trees for longer than any

The tree goose or hanging bird in roosting position

placental mammals have, ever come up with an imitation monkey like Dixon's "baraboo" when they've had no trouble evolving imitation dogs, moles, woodchucks, and flying squirrels?

One answer might be to point to the important role of chance in evolution. Maybe there aren't any giant rabbits because there just don't happen to be any giant rabbits, and no more need be said. But I suspect that there is more to it than that, and that we simply don't yet understand the reasons why evolution has missed so many apparently good bets. Some important facts about ecology, genetics, or the general principles of evolutionary change may be escaping us because we are busy trying to figure out why we have the animals we have, not why some animals can't get into the world. Maybe there are genetic or embryological reasons that prohibit marsupials from having big brains or mammals in general from having a dozen cervical vertebrae. Maybe there are fundamental ecological reasons for the absence of rabbucks. Perhaps there is some global truth about primate locomotion that explains why no monkeys ever took to the air. If so, then we need to start thinking seriously about the zoology of imaginary animals, and *After Man* is a good enough place to start.

Unfortunately, most of Dixon's animals aren't very instructive. They don't exist because they're anatomically, ecologically, or evolutionarily absurd. Take the purrip bat, for instance. Not only is it eyeless (a favorite assumption of Dixon's, even for tree dwellers and open-country predators), but it has its ears shoved forward to the tip of its snout, a move guaranteed to eliminate the phase differences between right and left ears needed for echolocation. Presumably it runs into things a lot. The lost carnivores

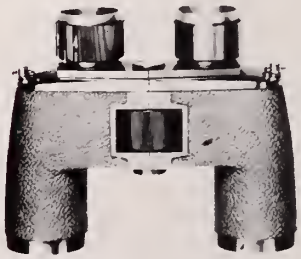
In 1974 we originated our epoch-making **Galapagos Islands Thrift Cruises**, *which for several years enabled many hundreds of budget-minded travelers who were interested in ecology, wildlife and photography to see these unique islands without luxurious trimmings but under expert guidance.*

We now again offer a budget program which includes some of the highlights which make a visit to this remarkable archipelago such a renowned tourist attraction. We explore five of the islands in order to view sea lions, iguanas and a large variety of birds, such as the famous Darwin's finches, boobies, frigates and gulls.

Galapagos Islands Thrift Program

APRIL 4 TO 14, 1982
JUNE 27 TO JULY 7, 1982
DECEMBER 26 TO JANUARY 5, 1983

Our program includes easy hikes on Santa Cruz to see tortoises roaming free and to the top of the dormant volcano at Sullivan Bay, and ample opportunities for swimming and snorkeling. It is ideal for young people and families with children and has been planned during periods of school and college vacations.



We do not claim that these programs are as comprehensive as our superb and unrivalled **Discover Galapagos** yacht cruises in August and October, 1982; but our meticulously supervised arrangements do provide you with a fascinating introduction to these wonderful islands—and at a third of the cost.

Each program is accompanied by one of our expert leaders and a naturalist guide who give informative talks and lead us in the field.

Before the week at the islands, we spend two days at the best hotel in Quito, Ecuador's lovely capital in the Andes.

Please send for the detailed brochure of these programs—we also specialize in expeditions to Greenland, Mount Kilimanjaro, the Himalayas and the Andes; wildlife safaris to see polar bears and seals in northern Canada and to Scotland, Borneo and Rajasthan; and archaeological tours to Peru, Morocco and Egypt.

of Dixon's Africa have been replaced by various species of meat-eating monkeys ("raboons"), which have "increased their speed by taking to their hindlimbs and adopting a totally bipedal locomotion." Anyone who thinks that bipedal primates are speedier than quadrupeds might find it instructive to try chasing an alley cat. On page 92, Dixon solemnly informs us that his "zarander" (a pig practicing to be an elephant) "like other mammals of the forest floor . . . has little sense of smell." This suggests that Dixon has never watched a coati or an opossum—or, for that matter, a pig. Even when Dixon has a good idea, he generally manages to spoil it with a mistaken pontification or an anatomical gaffe. For example, take a look at the drawing of the "falanx" reproduced on the following page. The incisors of this rat in wolf 's clothing are an inspired invention; they wrap up the stabbing canines and shearing premolars of a real carnivore into a single neat dental mechanism. But the drawing of the skull is an anatomical joke. It's obviously the skull of a herbivore, with a hopelessly addled jaw joint and ear region. My guess is that it was copied from a picture of a deer skull by an artist who didn't understand what he was looking at. This isn't Dixon's doing (his own drawings of the falanx, reproduced at the beginning of the book, are much better), but it's his fault for not fixing it.

I could go on for a dozen pages poking holes in Dixon's fabrications—especially if I let myself get started on his eyeless marsupial sloth that traps bugs by drooling into flowers—but that would give the wrong impression. Many of Dixon's evolutionary inventions are excellent, and the ones that are silly are generally silly enough or scary enough to be fun. As a piece of prediction, *After Man* is a nonstarter, but it's still an

Stargazing–with the great minds of history

From the astronomy of the ancient Greeks to our own physical exploration of space, man's preoccupation with the cosmos has dramatically influenced both our culture and values. In a skillful blend of science and biography, noted historian Vincent Cronin brings alive the cosmology of each age through its key figures. The result is a lively and thorough analysis of man's fascination with the universe—from the days of Pythagoras and Plato to the making of *Star Wars*.

entertaining bestiary. Why bother swatting Dixon's butterflies with a meat-ax? Well, in this case, swatting a few is instructive for two reasons: first, because the book's obsessively detailed fantasy is disguised as the product of scientific reasoning, and it's worth pointing out the difference; and second, because annotating the flaws in *After Man* has left me feeling a renewed confidence in the scientific status of evolutionary biology.

Evolutionary biology is in a dreadful funk at the moment. Some prefer to call it a scientific revolution, but "funk"—a state of depression and cowardice—seems like a more accurate description. Every learned journal and scientific meeting is sprinkled with papers bemoaning the shortcomings of Darwinists and telling us what we must do to be saved. One after another, Jeremiahs and iconoclasts are leaping onto their soapboxes and accusing their fellow evolutionary biologists of circular reasoning, hollow explanations, baseless assumptions, and general all-around mushheadedness. Some of these accusations have some real sting to them, but the cures being peddled along with them—genetics based on French anthropology, systematics rooted in Viennese philosophy, dialectical paleontology, and the like—are mere Laetrile. Hence the funk.

Reading *After Man* with a critical eye helps to dispel that funk. I feel dead certain that Dixon's raboons and purrip bats and sand sharks are not going to evolve in any world that might follow the extermination of man. I don't believe in his clawed armor-plated apes ("khiffahs") that weave huge, communal nests in the treetops and feed on

The falanx, one of the earth's principal carnivores, is a large doglike rat that preys on the herbivores of the plains and forests.

roots (!) and berries. I don't believe in the "strigers"—brachiating cats with opposable thumbs—that prey on the khiffahs. I can't believe for an instant that all the dogs, cats, foxes, goats, rabbits, and other Eurasian mammals that have been introduced to Australia over the last two centuries are going to step politely aside and allow the native marsupials to have a big evolutionary radiation (especially one featuring pouched monkeys and blind, slobbering sloths) in the next fifty million years, even if *Homo sapiens* is out of the picture. I'm not only sure that these products of Dixon's imagination *won't* happen (after all, the odds are a zillion to one against any detailed prediction about the distant future); I have some empirical and theoretical reasons for being fairly confident that they *can't* happen. And having such reasons is heartening because (unless I am just deluded) it means that evolutionary biology has enough predictive power to rule out a vast number of seemingly possible futures and that we probably understand evolution a good deal better than some of us are willing to admit.

Does this make evolutionary biology a real hard-core predictive science? Yes and no, but mostly no. For example, I'm willing to predict that if people become extinct and Australian marsupials don't, there will be animals in Australia ten million years later descended from domestic cats. Testing this prediction, however, is a bit sticky; the conditions of the experiment presuppose that no one is left to note the results. And this dismal presupposition is crucial to any sort of long-term evolutionary prediction. As long as *Homo sapiens* is running around disseminating diseases and poisons and edible garbage and foreign animals in all directions, turning forests into deserts and deserts into suburbs, and generally altering the environment in massive and unpredictable ways too fast for the process of adaptation to catch up, all bets are off about the future of terrestrial life in the long run. This is why Dixon's book has to begin by killing off its author and his audience. Beginning with that premise, you might concoct a more inventive or more plausible fantasy than *After Man*, but you can't develop a science that presupposes the absence of scientists. A predictive science of macroevolution is a contradiction in terms.

Matt Cartmill is professor of anatomy and associate professor of anthropology at Duke University.

Additional Reading

Humpback Whales (p. 30)

General books on whales containing information about humpbacks include: *Whales, Dolphins, and Porpoises*, edited by K. Norris (Berkeley: University of California Press, 1977); *The Year of the Whale*, by V.B. Scheffer (New York: Charles Scribner's Sons, 1969), which has an annotated bibliography; *The Whale: Mighty Monarch of the Sea*, by J.Y. Cousteau and P. Diole, translated from the French by J.F. Bernard (Garden City: Doubleday and Co., 1972); *The Great Whales*, by F. McNulty (Garden City: Doubleday and Co., 1974); and *The Book of Whales*, written and illustrated by R. Ellis (New York: Alfred A. Knopf, 1980). The January 1979 issue of *National Geographic* contains two articles on humpback whales. Marine biologist S.A. Earle recounts her observations from a research project on humpbacks in Hawaii in "Humpbacks: The Gentle Giants" (pp. 2–17), with photographs by A. Giddins. Interested in humpbacks as "floating islands of the sea," Earle set out to observe the whales in their own realm and went on various swimming expeditions with them. Zoologist R. Payne, who studied the complex songs of the humpbacks for twelve years, suggests their sound sequences may relate to social behavior and possibly to intelligence in "The Mysterious Songs" (pp. 18–25). The issue also contains "Songs of the Humpback Whale," an accompanying, detachable sound sheet reproducing some of the whale songs. Longer samples of humpback whale songs are available on two albums released by Capitol Records, *Songs of the Humpback Whale* (SW-60) and *Deep Voices* (ST-11598). *Natural History's* last arti-

cle on these mammals was "The Humpback Is Not Over the Hump," by J. Lien and B. Merdsoy (June–July 1979).

Wasps (p. 36)

H.E. Evans and M.J. Eberhard discuss the thynnine wasps briefly in their detailed, readable introductory paperback *The Wasps* (Ann Arbor: University of Michigan Press, 1970). There is much evidence that sperm competition is common in insects as a result of multiple matings. G.A. Parker analyzes the importance of sperm competition—which he defines as "the competition within a single female between the sperm from two or more males over the fertilization of the ova"—in his article "Sperm Competition and its Evolutionary Consequences in the Insects" (*Biological Reviews*, vol. 45, pp. 525–68). Parker explains how sexually selected adaptations that occur in response to the preadaptation of insects to sustaining a very high level of sperm competition have led to intense intrasexual pressures on the male. R. Thornhill presents the theoretical aspects of gift giving in male insects and explains the different types of nutritional paternal investment during reproduction in "Sexual Selection and Paternal Investment in Insects" (*American Naturalist*, vol. 110, pp. 153–63). "Daddy Water Bugs," with text and photographs by R.L. Smith (*Natural History*, February 1980, pp. 56–63), examines the unusual reproductive behavior of many species of giant water bugs in which the male carries and cares for the eggs.

Proteaceae (p. 42)

A. Huxley's *Plant and Planet* (New York: The Viking Press, 1975) begins with an account of plant evolution, briefly describes the major plant groups, then provides chapters on photosynthesis, structure and growth, and other aspects of plant life. The final five chapters deal with human exploitation and manipulation of plants. Illustrated with engravings, Huxley's work is readable and accurate; he uses colloquial plant names whenever possible and offers a good bibliography. *Structure, Form, Movement*, by H. Hertel, translated from the German by Scripta Technica, Inc. (New York: Rheingold Publishing Corporation, 1966), explores the relationship between biology and engineering, proposing that a closer partnership between the two fields would be mutually beneficial. Two other works relevant to "Protean Beauty" are *Art Forms from Plant Life*, by W.M. Harlow (New York: Dover Publications, 1974), and *Seed Biology*, edited by T.T. Kozlowski (New York: Academic Press, 1972).

Spacesuits (p. 50)

Suiting Up for Space, by journalist L. Millan (New York: The John Day Co., 1971), is a nontechnical, illustrated account tracing the development of the spacesuit. Beginning with the early suit designed for Mark Ridge by J.B.S. Haldane and Sir Robert Davis, the book then discusses the evolution of different spacesuits, ranging from the primitive suit fashioned for American daredevil Wiley Post to the multilayered Apollo life-support system. A.C. Guyton's *Textbook of Medical Physiology* (Philadelphia: W.B. Saunders Co., 1976) is a standard reference that gives some information on the physiological problems experienced at high altitudes; the section on aviation medicine, "Aviation, Space, and Deep-Sea Diving Physiology," is especially relevant to this issue's article on spacesuits. There are a number of Scientific Technical Aerospace Reports published by NASA offering technical but readable information on life-support systems and the physiological problems experienced in outer space. A collection of twenty-seven papers from a symposium, *The Second Conference on Portable Life-Support Systems* (Washington, D.C.: National Aeronautics and Space Administration Special Publication No. 302, 1971) is available from the National Technical Information Service, Springfield, Virginia 22151. For more physiological information, see *The Bioastronautics Data Book*, edited by J.F. Parker and V.R. West (Washington, D.C.: National Aeronautics and Space Administration Special Publication No. 3006, 1973). *Advanced Extravehicular Protective System (AEPS) Study*, edited by J.L. Williams, B.W. Webbon, and R.J. Copeland (Dallas: Vought Missile and Space Co., National Aeronautics and Space Administration Contractor Report No. 114382, 1972), is a readable, detailed account summarizing a study of life-support systems of the future. *Biomedical Results of Apollo*, edited by R.S. Johnson, L.F. Dietlein, and C.A. Berry (Washington, D.C.: Scientific and Technical Information Office, National Aeronautics and Space Administration, 1975), covers the different medical problems associated with people in space and provides information on life-support systems. It is available for sale from the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402.

Rita Campon

Endangered Pisces

The Great Lakes whitefish is exploited by both lampreys and humans

by Raymond Sokolov

When my father's father came to this country just after the turn of the century in the great wave of Jewish immigration from Eastern Europe, he did his greenhorn best to make a clean break and adapt to America. He struck out for the last frontier and made a quixotic stab at homesteading on bone-dry land in southern Utah. Cutting his losses after two years, he retreated back East during World War I and resettled in Detroit, where he had cousins and where, after so much unaccustomed mountain landscape and exotic brushes with Mormons and coyotes, he found the familiar comforts of urban life as well as a familiar fish.

In Detroit, as in any Great Lakes town of that period, whitefish abounded. This fleshy, mild-tasting relative of the salmon and the trout, known to ichthyologists as *Coregonus clupeaformis*, has many cousins in Europe, especially in the Russian empire my grandfather had escaped. There, the whitefish Linnaeus dubbed *C. lavaretus* was called *sig*, and Jewish families knew it best either smoked or ground up and poached in those quenellelike fish dumplings called gefilte fish.

The Great Lakes whitefish was not only a perfect substitute for the European, but it also grew on an American scale, averaging four pounds and occasionally breaking twenty. My grandmother, when I first knew her in the forties, was still continuing the old *shtetl* tradition of chopping whitefish for gefilte fish. Like other Jewish grandmothers, she tasted the raw fish paste as she worked, correcting the seasoning, and thereby risking the tapeworms that might have lurked in the mixture.

By then, my grandfather had professionalized his ancestral ties with whitefish; he ran a small fish market in Detroit. In our family, then, whitefish seemed like a very routine part of everyday life. Smoked whitefish for Sunday brunch, gefilte fish on holidays, and insidiously bony whitefish fillets sprinkled with paprika and broiled for dinner all seemed to me unremarkable features of growing up in the Great Lakes region. Cod was strange, lobster virtually unavailable, but whitefish was a staple.

All the while, doom was slithering toward us in the jawless, primordial form of the sea lamprey. These eellike creatures (*Petromyzon marinus*) are grotesque, with their single nostril, their fourteen gill holes, and their toothy, suctorial mouth pad. Lacking a central nervous system and endowed with a cartilaginous spine, they are not, in fact, eels (which are structurally more advanced and belong to the true or bony fishes, Osteichthyes). Along with the hagfish—similar members of the Agnatha class—lampreys are considered to be the oldest surviving vertebrates.

Ugly and nightmarish, the lamprey incubates peacefully enough for several years in streams, but then it enters its parasitic stage, propels its twenty-inch-long form into deeper water, and hunts for prey. Vampires of the aquatic world, lampreys attach their suctorial mouth to other fish. With their teeth, they rasp away at the victim's flesh, then drink its blood; their saliva contains an anticoagulant that thins blood and makes it easy for them to suck a whitefish dry.

Lampreys did not originally infest the Great Lakes. They were let in by the building of the New York State Barge Canal and the Welland Canal, which my other grandfather worked on as an engineer. The *coup de grâce* came when a thoroughfare for lampreys was inadvertently made by the construction of the Saint Lawrence Seaway. In the wake of the great seagoing vessels that began to ply the new water route to Lake Superior and Lake Michigan after World War II, *P. marinus* sinuously followed.

In other countries, such as France, the solution to the lamprey plague would have been obvious: eat them. Lamprey cooked in the style of Bordeaux (see recipe) is a classic dish, so

The Greak Lakes whitefish, Coregonus clupeaformis, *was abundant until the 1950s when sea lampreys nearly destroyed the population.*

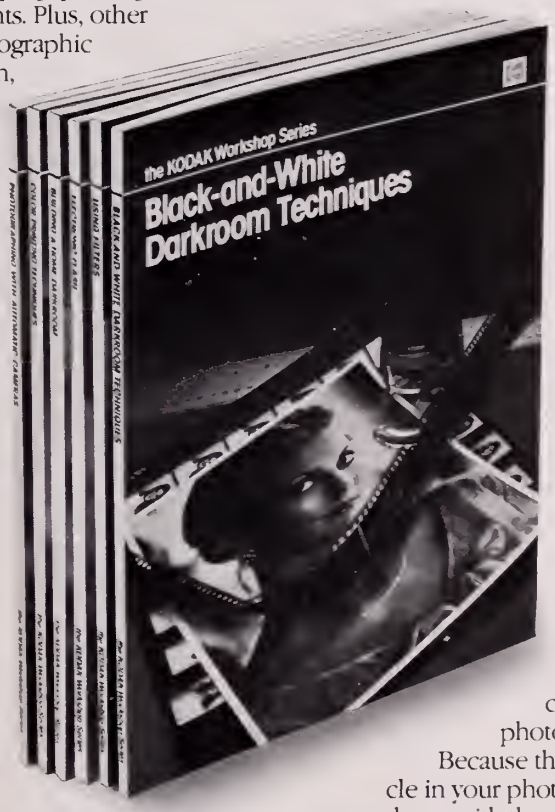
DEVELOP YOURSELF.



Pick your area of interest. And *teach yourself* with six easy-to-follow books in the new *KODAK Workshop Series.*

Each volume contains 96 pages of step-by-step pictorial instructions and costs only $8.95.

Black-and-White Darkroom Techniques details all the steps for developing, printing, and finishing black-and-white prints. Plus, other sections cover choosing photographic paper, dodging and burning in, mounting prints, and more.

Using Filters gives creative advice that helps you see and capture extraordinary images in color and black-and-white. It shows you how to create mood with color filters, add dazzle with special-effects filters, and render more natural colors and tones with correction filters.

Photographing with Automatic Cameras shows you how to get the most from your automatic camera. Especially useful for newcomers to 35 mm photography, it looks at how automatic cameras work and how to best use one. It offers special tips for capturing landscapes, portraits, and other subjects with an automatic camera.

Building a Home Darkroom tells you how to plan, what you'll need, and where to locate. From planning to construction to electrical work to plumbing, this book shows the step-by-step completion of a prototype darkroom in photographs and easy-to-understand illustrations.

Electronic Flash starts with the basics, giving thorough coverage of how, when, and where a flash can be used to enhance your photographs. Advanced techniques such as bounce and multiple flash are discussed.

Color Printing Techniques explains the basic procedures for making color prints from color negatives and color slides (including the new KODAK EKTAFLEX PCT Color Printmaking Products). Also included is information on equipment, darkrooms, retouching, and framing.

Choose one or all six titles in the new *KODAK Workshop Series* at your camera store or wherever fine photography books are sold.

Because the best way to put some muscle in your photographic development is to work out with the experts.

When it comes to photography, Kodak wrote the book.

popular it is even canned. In Finland, lampreys are smoked. Portugal, too, is a center of lamprey fishing. England once also favored the lamprey, but by 1850, interest in it had largely died out. Given the arduous and slightly macabre procedure (scalding, bleeding, and beheading) required to prepare the lamprey, it is not hard to see why it might scare off home cooks. Still, it could be easily cooked in a professional or factory setting, and it seems a shame that this vaunted delicacy was not actively promoted as a food source in this country when it suddenly became so plentiful. Instead, it was attacked as a useless vermin.

By the mid-fifties, sea lampreys had nearly destroyed the whitefish population of Lake Michigan (as well as that of the lake trout). The commercial catch fell below 100,000 pounds. Then a solution was found: a poison, called TFM, that kills lampreys selectively in the streams where they spawn. Since 1962, a joint United States-Canadian control program has effectively suppressed lampreys and largely protected other fish. The proof of this has been a dramatic rebound in the whitefish population. Commercial production from Lake Michigan rose to a recent peak of one million pounds.

Fish, however, are never simple. Last year, the Lake Michigan harvest sank to 800,000 pounds. Ron Poff, a fish expert with the Wisconsin Department of Natural Resources, blames the decline on "overexploitation of the whitefish population." The whitefish have responded to the pressure by maturing faster, he says, but they can only take so much.

Poff represents only one of the many groups that care intensely about whitefish in Lake Michigan. The state of Michigan bears an equal legal responsibility for the lake. It differs officially with Wisconsin over the respective conservational merits of gill netting versus trap netting. Commercial fishermen have their points of view. Tribal Indians fish the same waters under a separate set of rules and privileges. Meanwhile, the ordinary consumer, given half a chance, will eat fresh whitefish again and again with insatiable zest. And as long as there is whitefish to catch in Lake Michigan, people will throng to Door County, Wisconsin, to feast on whitefish at a traditional Wisconsin fish boil.

There are plenty of other reasons to visit Door County in the summer. The end of a big peninsula stretching out into Lake Michigan, it is a rural paradise of Holstein cows and cornfields and cherry orchards with a water view, all only an hour's drive from gritty Green Bay. On my way through the county last summer, I stopped to pick a bucket of tart pie cherries at one of the commercial orchards that invite amateurs in to pick what they need for a modest price. Special folding wooden ladders planted in the sandy soil permit the picker to reach whatever point in the tree he wants. Large families were contentedly filling long strings of buckets.

In Sturgeon Bay, I bought smoked whitefish for $2.75 a pound at a market that does its own smoking out back over maple, imparting a mild flavor to the fish's flesh, which is more delicate than the smoking done for shipping to New York deli counters.

In the resort village of Fish Creek, I headed for Jan and Andy Coulson's White Gull Inn, a white clapboard building dating back to 1896, which has landmark status in Wisconsin. There I sat down on the patio in back to watch Russ Ostrand preside over the best-known fish boil in the county.

Russ is a big, warm fellow who works in a shipyard in Sturgeon Bay and literally moonlights as a chef and strolling accordionist at outdoor banquets. In the winter, he runs coon feeds and venison feeds for hunters and civic groups. But in the summer, on Wednesdays and weekend nights, he concentrates on fish boils and gives hundreds of tourists a taste of what life was like in the old Wisconsin lumber camps where fish boils began.

The method is simple, quick, and requires nothing more than an ample

At a Wisconsin fish boil, left, Russ Ostrand adds potatoes to a caldron of boiling water. Meanwhile, guests at the White Gull Inn, right, wait for the thick whitefish steaks to be added and the meal to begin.

supply of fish, potatoes, salt, hardwood, and a big pot. At the logging camps, it was the ideal way to get dinner together for a mob of ravenous lumberjacks.

Ostrand starts by building a large wood fire from logs of oak, maple, cherry, and beech. On a metal stand sits a twenty-two-gallon caldron filled with twenty gallons of lightly salted water. In that pot, Ostrand first cooks red Wisconsin potatoes. He lowers them into the water with a perforated metal basket whose handle will later permit him to extract the potatoes from the pot. In an evening, he will boil forty pounds of potatoes for eighty people, and eighty pounds of whitefish, cleaned and cut into thick steaks. The only trick is timing. It takes just a few minutes to cook the fish.

When it's ready, Ostrand gingerly tosses a coffee can of kerosene into the fire, which surges up in twenty-foot flames. The conflagration is spectacular, but it also has a practical point. It makes the pot boil over, thus purifying the fish of any scum and oil that have come to the top of the pot during cooking. Then, out comes the fish, ready to be eaten in one of the greatest fast-food banquets ever devised.

Raymond Sokolov's new book, Fading Feasts *(Farrar, Straus and Giroux), is a collection of food columns that first appeared in* Natural History.

Eve Hecht's Gefilte Fish

2 pounds whitefish
2 pounds yellow pike
1 pound carp
3 medium onions
4 tablespoons salt
3 tablespoons sugar
3 eggs, lightly beaten
2 tablespoons matzo meal
Pepper
3–4 carrots, scraped and cut in rounds

1. Have your fish man fillet the fish. Take the bones and fish heads with you. And try to get an extra head—it will improve the broth.
2. Grind the fish with two of the onions, coarsely, in a meat grinder or a food processor.
3. Transfer to a wooden bowl and continue chopping with a mezzaluna (a half-moon–shaped chopper) as you work in two tablespoons salt, one tablespoon sugar, the eggs, the matzo meal, and enough water (about ¼ cup) to produce a smooth, light paste. Set aside.
4. Put the fish heads and bones as well as the remaining salt, and sugar, pepper, carrots, and the remaining onion (peeled and sliced) into a large pot of wide diameter. Cover these ingredients generously with water and bring to a boil. In a separate pot, bring three quarts of water to a boil.
5. When the first pot comes to a boil, begin making the fish balls. Keeping your hands moist with cold water, form spheres roughly the bulk of a jumbo egg (they will expand when cooked) and drop them, one by one, into the pot with the fish bones. The water should be kept at a slow simmer as you continue to add fish balls. When the paste has been completely used up, continue simmering for about 1½ hours. Add additional boiling water from the second pot as necessary, so that there is enough to float the balls.
6. Remove from heat and let the fish balls cool in cooking liquid.
7. Remove the fish balls to a serving platter.
8. Strain the cooking liquid. Pour it into a jar and refrigerate. It should gel. If it does not, rewarm the liquid and dissolve a package of gelatine into it. Test the sauce by putting a teaspoon of it on a saucer in the refrigerator: If the liquid does not gel, add more gelatine and continue until it does. Refrigerate.
9. Serve fish balls with gelled fish aspic and horseradish.

Yield: 8–10 servings

Lamprey Bordelaise

(Adapted from Raymond Oliver's *La Cuisine*)

1 live 2-pound lamprey
1 cup sauterne or other sweet white wine
6 tablespoons olive oil
8 leeks, cut into green and white parts, well washed, and sliced into 5-inch strips
3 medium onions, peeled and chopped
8 cloves garlic, minced
4 shallots, minced
2 carrots, scraped and diced
4 celery hearts, sliced
2 tablespoons flour
3 cups dry red wine
1 sprig parsley
1 bay leaf
¼ teaspoon dried thyme
¼ pound smoked ham or prosciutto
Black pepper
Salt
2 tablespoons butter
¼ cup Armagnac

1. Put the lamprey into a rough wooden box with no lid. Pour a slow stream of very hot but not boiling water over the lamprey, which will squirm and, in so doing, scrape off the film that covers its skin. Do not scald the lamprey to death. As soon as it has been doused on all sides, pour on cold water to revive it and scrape off any remaining film with a knife.
2. Tie a string around the lamprey's neck and suspend it from a hook over a saucepan containing the sauterne. Cut off six inches of the lamprey's tail (reserving this piece) and let the fish bleed into the wine, stirring constantly until the bleeding is complete and the mixture is well blended.
3. Make several vertical incisions just below the cartilaginous backbone and pull it out in one piece. Cut off the head and discard. Cut the body into six or eight even slices. Remove the gut and discard.
4. Marinate the pieces in the blood-wine mixture for three hours.
5. Preheat oven to 300 degrees.
6. Heat four tablespoons of the oil in a saucepan and cook the onion, garlic, shallot, carrot, celery, and the green parts of the leek until soft. Stir in the flour, cook for one minute, and add the reserved tail, the red wine, parsley, bay leaf, thyme, ham, pepper, and a little salt. Bring to a boil, cover, and cook in oven for two hours.
7. Add lamprey and its marinade to the mixture from step 6, stirring constantly as you bring it to the boil on top of stove. Reduce heat and simmer for five minutes. Remove lamprey pieces and set aside. Discard the tail.
8. Cover the saucepan and return to oven for seven hours.
9. Heat the remaining oil in a saucepan with the butter and cook the white parts of the leeks until golden. Add lamprey slices and Armagnac. Flame. Strain the sauce over the fish and stir carefully so that fish pieces don't break.
10. Cover saucepan and simmer over lowest possible heat for one hour, or less if the fish pieces seem about to break up. Serve with boiled potatoes and croutons.

Yield: 4 servings

The Possibilities are Endless.

Shutter-Priority: 1000 S 6

Six-mode exposure control. System versatility. Newer electronics for wider applications.

The Canon A-1 is one of the world's most advanced automatic SLR cameras. Combining the finest in optical and mechanical engineering with the most sophisticated electronics, it's technology applied to give you the ultimate in creative control. At the touch of a button.

Depending on your subject, you can choose from six independent exposure modes to achieve the results you want:

1 Shutter-Priority: You select the shutter speed, to freeze the action and prevent camera shake or create an intentional blur. The A-1 automatically selects the appropriate lens opening.

2 Aperture-Priority: Control the area in focus by selecting the lens opening for the effect you want. The A-1 matches with the right speed.

3 Programmed: When you need to shoot fast, just focus. The A-1 will select *both speed and aperture* for great results.

4 Stopped-Down: For extreme close-up or specialized photography, a bellows, a microscope or almost anything can be attached to the A-1. It's still automatic.

5 Flash: Totally automatic flash photography, of course, with a wide variety of Canon Speedlites to choose from.

6 Manual: Yes. For those times when you absolutely want to do it all yourself. To experiment. To explore the possibilities.

There are over forty fine Canon lenses ranging from Fish Eye to Super Telephoto, plus accessories to meet every need. If you can't photograph your subject with a Canon A-1, it probably can't be photographed.

From the sophistication of its LED viewfinder display, to a ruggedness that allows up to five-frame-per-second motor drive, the Canon A-1 represents an incredible technology. At a price that makes owning one a definite possibility.
